Abstract: the research team aims to build upon previous research using speleothems from caves in northwest and southwest madagascar to reconstruct late pleistocene and holocene climate from a southern hemisphere tropical site and to examine the role of climate in the ongoing alteration of the island's ecosystems. using previously collected samples, the researchers plan to construct high-resolution (decadal) multiproxy climate records from the last glacial maximum (26,000 years ago) to the present from high-resolution (near annual resolution) analyses for periods of particular climatic interest (e.g., the 4.2 ka event, younger dryas). the researchers will extract organic matter from the speleothems across an interval of marked change in speleothem delta carbon-13 and measure biomarker concentrations and the same to test a newly developed subsistence shift hypothesis for the disappearance of madagascar's megafauna. speleothem fluid inclusion water isotopes, combined with carbonate oxygen isotopes, will be examined as a tool to estimate paleotemperatures over the past 117,000 years for southwest madagascar and the past 26,000 years for northwest madagascar. the goal of the project is to produce long, high resolution records of climate from the southern hemisphere tropics. these data will aid in understanding the influences of inter tropical convergence zone (itcz) migration, western indian ocean sea-surface temperature (sst), and regional precipitation. in particular the project will investigate whether the indian ocean monsoon in the northern versus southern hemispheres vary in or out of phase at various timescales and test current hypotheses on tropical rainfall variation. the potential broader impacts include the integration of science across the fields of paleoclimatology, anthropology, and biology to provide

background climate data needed for interpreting the impact of climate on a variety of fossil communities of the past. the research team will produce educational materials and exhibits prepared for a general audience to heighten public awareness of tsimanampesotse national park's natural history, bio\*\*diversity\*\*, and extinction events. the project will help develop a better understanding of the causes of decadal-scale climate variability which can aid in forecasting possible changes in rainfall in a country that experiences severe drought and flooding on inter-annual time scales and relies on subsistence farming for survival. this project includes supporting an early career female post-doctoral scholar in the united states and collaboration with malagasy scientists and students as well. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: CAREER: Leveraging Signal Structure for Cost-Sensitive Adaptive Sampling

Awardee: Portland State University

Amount: \$441,193.00

Abstract: a persistent challenge to scientists and engineers is the ability to rapidly sense the environment. whether monitoring for harmful air pollutants, wildfires, or low oxygen levels in lakes, an essential task is to determine all locations where a factor of interest reaches a critical level. to solve this problem, practitioners are increasingly utilizing mobile sensors such as those deployed on unmanned vehicles. while these provide a safe means of exploring large spatial regions and hazardous environments, they also require extensive planning to ensure the most relevant measurements are collected and to manage battery life. this project will overcome these issues through the design of adaptive sampling algorithms, which automatically guide sampling vehicles to the most important regions while accounting for the realistic costs associated with the measurement process. the resulting approaches will provide general-purpose solutions to environmental sampling

that can be easily utilized by practitioners while also accounting for the realistic challenges that typically prevent adaptive methods from translating into practice. furthermore, this research will support education and **\*\*diversity\*\*** through the development of curriculum for a high school course on unmanned aerial vehicles as well as a citizen science campaign that leverages adaptive sampling to benefit one of the nation's largest urban parks. the objective of this project is to design and analyze cost-sensitive adaptive sampling algorithms for the problem of level set estimation. novel adaptive sampling techniques will be developed under three forms of level set structure: (1) boundary smoothness, where no domain or side knowledge is available, (2) known similarity structure that indicates which locations should have similar measurement values, and (3) unknown cluster structure, where the signal of interest is constant within each cluster of locations, and the goal is to simultaneously learn the cluster structure and measurement values. for each case, principled algorithms will be derived based on recent developments from the fields of active learning, multi-armed bandits, and reinforcement learning, with the goal of providing improved empirical performance, rigorous theoretical characterization, and incorporating realistic costs such as the distance traveled while sensing. algorithms will be evaluated on real-world datasets including those measuring air quality and geothermal energy prospects. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: NSFGE0-NERC:Collaborative Research: Chemistry and Biology under Low Flow Hydrologic Conditions Beneath the Greenland Ice Sheet Revealed through Naturally Emerging Subglacial Water

Awardee: Indiana University

Amount: \$440,249.00

Abstract: this project is jointly funded by the national science foundation's directorate of

geosciences (nsf/geo) and the national environment research council (ukri/nerc) of the united kingdom (uk) via the nsf/geo-nerc lead agency agreement. this agreement allows a single joint us/uk proposal to be submitted and peer-reviewed by the agency whose investigator has the largest proportion of the budget. upon successful joint determination of an award, each agency funds the proportion of the budget and the investigators associated with its own component of the work.

weathering is an important process that releases nutrients that are essential for life from rocks and minerals in the earth's surface. this project seeks to understand the effect of large glaciers on weathering processes beneath the greenland ice sheet and the consequences for life. during summer, nutrients and other products are flushed out of the greenland ice sheet with water from melting ice. while these products have been sampled in spring and summer, it is not known how weathering processes are different during winter. in this project, researchers will sample the seasonal ice that forms in front of two of greenland's glacial outlets, isunnguata sermia and leverett glacier, during the freezing months to assess the chemistry and microbiology processes that reflect wintertime conditions beneath the ice sheet ? periods when input of fresh meltwater is minimal. these samples will increase knowledge of winter conditions under the greenland ice sheet and help better understand the interior portions of the ice sheet which are largely inaccessible. such information will help in assessing past conditions, when colder atmospheric conditions resulted in minimal meltwater input through the ice sheet and to the glacial bed. these analyses will inform understanding of the role of glaciers on earth's nutrient cycles presently, under past ice age conditions, and in a future deglaciating world. the greenland ice sheet is a major exporter of biologically important elements to the world's oceans. however, most of our knowledge of chemical and biological fluxes from the ice sheet comes from the summer outflux of outlet glaciers whose channelized waters contact only a limited portion of the glacier bed. the majority of the glacier-bed interface contains slow-flowing, distributed waters not representative of this flux. the project will test the hypothesis that overwinter chemical and biological processes under outlets of the greenland ice sheet differ substantially from summer outflow and represent a window into widespread, but typically

inaccessible, distributed flow. the principal sample collection method will be early spring coring of naled ice that forms at glacial termini from wintertime subglacial flow. chemical, mineralogical, and biological constituents of this flow will be compared to material emerging from the initial, peak, and terminal phases of the melt season. elsewhere in the arctic, the chemistry of frozen overwinter subglacial material shows significant limitation in oxygen or sediment supply compared with even the first spring melt, supporting the idea that naled ice reveals a unique overwinter system. the naled ice and outflow of isunnguata sermia and leverett glacier will be sampled over two years. these west greenland outlets differ by more than an order of magnitude in the size of the catchments they drain, thereby testing the effect of scale on biogeochemistry. naled ice structure will be characterized by ground penetrating radar and ice borehole temperature profiles. the aqueous geochemistry, stable isotopes of carbonate and sulphate, and mineralogy of the suspended sediment of ice and water will be assessed. these analyses will document changes in the mineral flux and supply of atmospheric gases at the glacial bed between winter low flow conditions and peak summer melt. microbial abundance, **\*\*diversity\*\***, metagenomics, and stable isotopes of biomass will also be measured to understand the concomitant relationship between geochemical conditions and biological communities. researchers will incorporate findings into a number of outreach efforts including developing a new curriculum module for the center for earth and environmental sciences, providing research opportunities for underrepresented students as part of the bridge to research program and preparing hands-on activities for the market science program. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Rare Isotope Reaction Studies for Nuclear Structure and Astrophysics

Awardee: Rutgers University New Brunswick

Amount: \$440,000.00

Abstract: this award will support the principal investigator and her group of early career scientists to advance our understanding of the structure of atomic nuclei as well as their reactions and synthesis in exploding stars. nearly all elements heavier than iron are made in stars and stellar explosions through processes that involve the capture of neutrons. to learn more about those processes the pi will lead experiments using beams of rare isotopes, concentrating on neutron-rich nuclei. this research program will use state-of-the-art instruments and accelerator facilities in the u.s. the project will also serve to enhance the **\*\*diversity\*\*** of the nuclear science workforce. the participation of these early career scientists in forefront research and the development of scientific instruments will prepare them for careers in higher education and fundamental and applied research at national laboratories and in industry. light-ion transfer reactions will be studied with beams of rare isotopes with energies near the coulomb barrier and about 45-mev per nucleon. studies will concentrate on neutron-rich nuclei near the  $n=50$  neutron shell closure and light nuclei important for understanding the synthesis of nuclei in stars and their explosions. these studies will be carried out with accelerated beams of rare isotopes at michigan state university, first with the reaccelerated (rea) beam capability and starting in 2022 with the facility for rare isotopes beams (frib). additional experiments will be performed at the atlas accelerator facility at argonne national laboratory. at frib the focus is to constrain the shape of the potential that binds neutrons in a neutron-rich nucleus and, therefore, extract spectroscopic strengths and direct neutron capture rates with reduced dependence on theoretical model parameters. the neutron-transfer reaction with deuterated targets has been validated as a surrogate for neutron capture when reaction products are measured in coincidence with gamma rays. therefore, both charged particles and coincident gamma radiation will be measured with gamma-array orruba: dual detectors for experimental structure studies (goddess), where the oak ridge rutgers university barrel array (orruba) is coupled to large, highly segmented arrays of high-purity germanium gamma-ray detectors. the results will be compared with theoretical predictions of nuclear structure and reactions away from stability and disseminated as input into calculations of nucleosynthesis in stars and their explosions. this award reflects nsf's

statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: The Excited State Behavior of Ru(II) Photodrugs

Awardee: University of Texas at Arlington

Amount: \$440,000.00

Abstract: with this award, the chemical structure, dynamics, and mechanism-b program is supporting the research of professor sherri mcfarland at the university of texas, arlington to examine the excited state photophysics and redox properties of ru-based photosensitizers. photosensitizers are compounds that can trap the energy of light and use it to effect a useful chemical reaction. examples of this include solar energy conversion, catalysis, and photodrugs. this project focuses on a particular class of such photosensitizers that show promise in cancer therapy, but have many unanswered questions about their mode of action. the work will investigate the fundamental photophysical and electrochemical properties of oligothiophene-containing ruthenium compounds specifically, and reveal the details of photocatalytic mechanisms in which they can participate. it will also explore how the behavior of these photosensitizers can change as a function of its environment, e.g., agglomeration effects and the influence of simulated biological structures. the proposed work will train graduate and undergraduate students in highly multidisciplinary research at

the interface of chemistry, biology, physics, and engineering. the knowledge and skills these trainees will acquire will give them tools necessary for success as future research scientists in cutting-edge multidisciplinary fields ranging from photomedicine to solar energy conversion and chemical biology. the broader impact objectives will simultaneously equip tomorrow's leaders with skills in science communication and expose them to entrepreneurship and commercialization as it relates to bringing scientific discoveries from the laboratory to society. it will also provide curriculum-based research opportunities for undergraduate students that would otherwise not have the opportunity to experience scientific research in a real-world laboratory setting, expanding **\*\*diversity\*\*** in our next generation of emerging scientists.

this project project will examine the excited state photophysics and redox properties of oligothiophene-containing  $\text{Ru(II)}$  complexes, compounds that have important applications as photosensitizers in fields ranging from solar energy conversion to photodrugs. the project also aims to develop the photophysical model(s) for these photosensitizers in complex biological environments. we will synthesize and characterize oligothiophene-appended  $\text{Ru(II)}$  photosensitizers,  $[\text{Ru(II)}_2(\text{ip-nt})]^{2+}$  that differ in the number of thiophene rings (nt), the types of substituents on the thiophene rings, and the co-ligands (ll). the modifications are designed to systematically vary redox potentials and triplet state characteristics, and to alter the covalent and noncovalent associations typical of oligothiophenes. electrochemical and photophysical techniques will be used to test hypothetical photoredox catalysis mechanisms in complex substrates, where synthetic and cell-derived vesicles will be used to model how photosensitizer response modulates in confined matrices, e.g., a lipid bilayer. the results will advance the field of  $\text{Ru(II)}$ -oligothiophene photosensitization. with a mechanistic understanding of oligothiophene-containing  $\text{Ru(II)}$  photosensitizers, there exists the opportunity to create better next-generation photosensitizers for photocatalytic applications. the broader impact activities are equally focused on exposing stem scientists to science communication and entrepreneurship based on past translational research and commercialization efforts related to light-molecule interactions. the training program will cover outreach, education, and curriculum, emphasizing the process from

fundamental discovery to societal application, and provide opportunities for researchers to improve their science communication skills. curriculum-based research opportunities for undergraduate stem students will be designed and delivered to ensure that a larger percentage of these students receive hands-on research experience during their degree programs. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Evaluating Climate Change and Kill Mechanisms Associated with the End-Cretaceous Mass Extinction: A Model-Data Comparison Approach

Awardee: Louisiana State University

Amount: \$439,432.00

Abstract: sixty-six million years ago at the cretaceous-paleogene boundary (kpb), an asteroid impact in the yucatán peninsula resulted in the loss of about 75% of all species on earth. as the most recent, well documented, and rapid mass extinction in earth's history, study of the kpb extinction is ideal for understanding the effects of climate change on bio\*\*diversity\*\*. however, the causes of the kpb extinctions remain uncertain. this project will use a combination of novel climate model simulations and geologic records to explore climate change and kill mechanisms associated with the asteroid impact. measuring various geologic records from across the kpb will constrain the types and magnitudes of emissions from the asteroid impact. these emission estimates will then be used in climate model simulations to determine the earth system responses to the asteroid impact through time. project results will provide a mechanistic understanding of kpb extinction, which, in turn, will improve interpretation of many records from this time period, deliver insights into ecosystem collapse and recovery, and lead to valuable climate model development. outreach activities include creation of a kpb exhibit, develop of a geochemistry high school project, recruitment of three underrepresented undergraduate interns, and engagement of student researchers at the university

of texas rio grande valley, a hispanic majority university. to determine the relative importance of various processes that could have led to the kpb extinction and subsequent environmental recovery, the pis will use an earth system model to perform kpb simulations that mimic forcings from the asteroid impact. the model contains an explicit aerosol resolving scheme and high-top atmosphere, both essential for capturing the processes associated with these perturbations. further, development and implementation of an ocean biogeochemistry module will allow for direct comparison with paleontological, chemical, and isotopic records across the kpb. the pis will also collect high resolution soot, temperature, and biomarker records to constrain and validate the kpb simulations. samples will be analyzed for soot and polycyclic aromatic hydrocarbons to test the asteroid impact fires hypothesis and provide refined soot emission data for the simulations. new estimates of temperature change after impact will be generated from phosphatic microfossils and biomarkers. these records will provide sub-millennial to millennial scale constraints on temperature, and in combination with simulations and soot estimates, a means to backout co2 emission associated with the impact. finally, high resolution biomarker work will shed light on the rate of marine planktonic recovery, which will be compared with the ocean biogeochemistry simulations. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Microdiversity drives ecosystem function: SAR11 bacteria as models for oceanic nitrogen loss

Awardee: Georgia Tech Research Corporation

Amount: \$436,628.00

Abstract: this project studies how low oxygen availability influences the bio\*\*diversity\*\* and ecological role of sar11 bacteria, one of the most abundant microbial groups in the ocean. the work involves oceanographic sampling across a range of oxygen and nutrient levels in the eastern tropical north pacific ocean. using a combination of genomic, microbiological, and biogeochemical methods, the study identifies the mechanisms by which sar11 strains diversify into separate niches and species and contribute biochemically to the ecosystem, likely through removing nitrogen from seawater. the project equips the next generation of researchers and educators, notably those from underrepresented minority groups, to use oceanographic, genomic, and microbiological concepts to meet contemporary scientific challenges. this goal is met through a combination of bioinformatic workshops that target undergraduate students from the university system of puerto rico, middle school teacher-training workshops, and middle or high school teacher internships in the investigator?s labs. this multifaceted research and educational agenda fills a gap in our understanding of marine biological \*\*diversity\*\*, identifies the contribution of sar11 bacteria to nutrient and carbon cycles in low oxygen oceans, and provides lessons and analytical tools to study microbial processes in other ecosystems. this project has two aims. aim 1 employs comparative metagenomic and single-cell genomic analyses to identify metabolic properties that distinguish sar11 clades from low oxygen regions and processes of selection or gene flow operating across the clades. aim 2 combines microbial transcriptomics, incubation experiments with isotope tracers, and

culturing to delimit the oxygen and nutrient conditions that define the niche space of each sar11 clade and to correlate sar11 gene transcription with community biochemical outcomes, including nitrogen loss through denitrification. the results of these aims and the informatic methods used to probe microbial micro\*\*diversity\*\* are disseminated through genomics-focused undergraduate workshops, and new teacher-training educational modules, including lab-based modules focused on the importance of microorganisms under environmental change in the oceans. data, manuscripts, and informatics workflows from this project are made publicly available. the results are critical for resolving the processes that create and sustain microbial \*\*diversity\*\* in the oceans and informing biogeochemical models that predict how \*\*diversity\*\* influences ecosystem processes. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: CAREER: Long Document Summarization with Question-Summary Hierarchy and User Preference Control

Awardee: Regents of the University of Michigan - Ann Arbor

Amount: \$436,313.00

Abstract: in an era when long documents are produced at an overwhelming speed, a reader may not have time even to skim over a document to decide which topics deserve a detailed look. the goal of this career project is to build text summarization systems that can understand and aggregate information from long documents, so as to allow users to explore their content with summaries that are generated in styles they prefer. the summarization tools will make long documents more accessible and comprehensible, easing the knowledge learning experience of the general public. researchers and practitioners can also use the tools to summarize long documents relevant to their work, and educators can incorporate them in their classes to bolster students' reading and writing skills. the project also broadens the investigator's efforts of engaging young students in immersive

research opportunities, allowing them to participate in the design and implementation of advanced summarization systems. this project develops a new summarization framework for long documents in which article-level abstractive summaries provide an overview, and a question-summary hierarchy presents different levels of details. the technical contributions of this project are three-fold. first, the quadratic time complexity of state-of-the-art summarization (e.g., transformer) is reduced by using adaptively predicted sparse attentions and augmented with a knowledge encoder. second, an open-ended question generation model fills automatically learned question templates to produce concrete questions that are coherent within the question-summary hierarchy. third, summaries are tailored to user-specified styles via iterative adjustments during generation, reflecting important advice in plain-language guidelines. this project experiments with new datasets collected from government reports, since their length, topic **\*\*diversity\*\***, and formulaic verbiage embody many common challenges for long document summarization. new evaluation methods are also designed, with cloze questions to target common erroneous generations, and with model confidence metrics to pinpoint errors without using references. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: The Petabyte Project for Fast Radio Transients

Awardee: West Virginia University Research Corporation

Amount: \$432,848.00

Abstract: we are in a golden era in the investigation of flashing, short-duration astronomical events detected by radio telescopes. progress in understanding novel, highly luminous phenomena like fast radio bursts (frbs) and highly intermittent pulsars is being enabled by the broad availability of archives, new observing systems on a host of telescopes worldwide, and extensive computing systems in place to provide throughput for huge amounts of data. this field has rapidly evolved in the past decade. searches for such transients have been done by constantly evolving analysis techniques, each improving on the last. however, new techniques are typically applied to only a small set of data. a research group at west virginia university (wvu) will undertake "the petabyte project," which will harness many diverse archival and new data sets to perform an unprecedented uniform search across multiple observing systems and radio frequencies. this search for transient events has key analysis structures in place that were not available in past searches, including a systematic check of completeness of the constituent surveys, and a rigorously tested machine-learning-based event classifier. to broaden the impact of their work, the researchers will work with two strong existing outreach programs at wvu, the science public outreach team (spot) to introduce area high-school students to machine learning applications, and the pulsar search collaboratory (psc) summer program, to enable high school students to participate in the research by helping to classify radio sources. there will be several key scientific, software, and data outcomes from this search. the work will lead to the discovery of new frbs and pulsars, particularly at high radio frequencies where few searches have been done. it will provide the first statements on the completeness of frb searches as a function of dispersion measure (distance) and radio frequency, leading to new knowledge on the **diversity** and range of frb properties. the team will also provide the first broad, blind multi-frequency exploration of extreme intermittency in the radio pulsar population. all code generated by this project will be open-access and accompanied by in-depth documentation, allowing broad use of the unified transient data read/write tool, machine-learning suite, pipeline, and completeness assessment software. labelled search products will be made public on a permanent server for use in future interference, fast-transients, or machine-learning

studies. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Disentangling biological and environmental drivers of diversification in the Andean flora

Awardee: University of Hawaii

Amount: \$431,424.00

Abstract: the tropical andes of south america is one of the world's richest bio**diversity** hotspots. this **diversity** likely evolved due to the complex environmental and geological history of this region. however, exactly how plant **diversity** arose from the combination of mountain uplift, the development of new habitats, and species interactions is unclear. this research aims to understand how these factors led to plant **diversity** in cloud forests and high-elevation grasslands. the researchers will develop new software to compare plant genomes to understand the ancestry of four groups of flowering plants in the andes. the project will also result in new mathematical models to test the importance of different factors in shaping **diversity** in these plant groups. these new methods will have broad application to studies of bio**diversity** in the andes and beyond. additionally, this project aims to train the next generation of scientists in the study of bio**diversity** through a variety of interrelated activities, including: (1) a course for undergraduates to do guided

genomic research; (2) collaborative training for students; and (3) computational training for diverse students. the project will first establish well-supported phylogenetic hypotheses for each of the four focal clades of andean plants using low-coverage and targeted genome sequence data. samples will be collected from colombia as well as museums. this work highlights the importance of natural history collections in cutting-edge biological research, and new fieldwork will add to those collections. a component of the research will be to develop new approaches to address complexities common in plant genomes, including polyploidy and paralogy, that can affect estimates of evolutionary relationships. these methods will be made available through open-source software such that other researchers can easily estimate phylogenies and examine support for phylogenetic hypotheses using sequence data. second, the project will develop new models that jointly infer the roles of dispersal and trait evolution in species diversification. these methods will be applied to phylogenomic, morphological, and distribution data collected for this project. these methods will also be made publicly available for widespread use. finally, by comparing the roles of biogeographic and ecological processes in generating **\*\*diversity\*\*** in these clades, the research will address the generality or idiosyncrasy of the processes facilitating rapid radiation in tropical andean plants. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: A Model of Generalized Ingroup Recognition Advantage

Awardee: University of California-Riverside

Amount: \$431,338.00

Abstract: this award is funded in whole or in part under the american rescue plan act of 2021 (public law 117-2). people often have worse recognition memory for individuals who are not (versus are) in their racial group. this well-known cross-race effect can lead to racial disparities. as one example, in the us criminal justice system nearly a third of wrongful convictions that later are overturned were

based on errors made in cross-race identification. the cross-race effect would seem to be specific to faces: a glance at a face quickly reveals information about race, gender, age, and other social categories. yet many objects beyond a face, or even beyond a person, may signal group membership and cause a recognition bias. this research investigates the possibility that the ingroup recognition advantage exemplified by the cross-race effect is a general recognition bias. this research has the potential to transform our theoretical understanding of social influences on perception and cognition, including the basic psychological mechanisms that contribute to racial disparities.

this project builds upon research in social psychology, developmental psychology, cognitive neuroscience, and vision science to develop a comprehensive model of ingroup recognition and examine its social impact. the project is organized around three sets of experiments, all using a basic paradigm in which participants complete a learning task followed by a recognition task. the first set of experiments aims to differentiate two causes of an ingroup recognition advantage: people may better recognize information relevant to their own group because (1) they have more lifetime experiences with their group and thus have perceptual expertise, and/or (2) they are more interested and motivated to attend to their own group. each cause can be tested with experiments in which participants form new groups and are exposed to objects with which they have no prior experience but are related to their group or another group. a second set of experiments examines whether an ingroup recognition advantage occurs to the same extent for different groups to which one belongs, and a third set examines how the generalized ingroup recognition advantage can lead to stereotypic judgments of others. under conditions of tight experimental control, this research tests a novel model that accounts for: (1) the mechanisms and boundary conditions of ingroup recognition; (2) the qualitative nature of the cognitive processes underlying the generalized ingroup recognition advantage; and (3) the implications of the generalized ingroup recognition advantage. the interdisciplinary and integrative nature of this research has implications that are relevant to social psychologists, policymakers, legal scholars, law enforcement, and the general public, and it can inform interventions to reduce stereotyped judgments. the project also provides

specialized training to students at a minority-serving institution (msi) that ranks highly in terms of **\*\*diversity\*\***, social mobility, and graduation rates. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: IntBIO COLLABORATIVE RESEARCH: Deep Time, Development, and Design: Evolution of shark skin teeth from genotype to phenotype to prototype.

Awardee: Harvard University

Amount: \$431,276.00

Abstract: the skin of sharks is unique among vertebrate animals because it contains tooth-like scales, called dermal denticles, that create a hard external armor. these tooth-like denticles evolved over millions of years and equip the shark with hydrodynamic skin that reduces the cost of moving through the water. this advanced streamlining is currently a subject of great interest, with many industries attempting to take advantage of shark skin technology to create more efficient swimming designs. this project aims to provide a complete integrated understanding of shark denticles: how they form in embryonic sharks, how denticle shape has changed over years of evolution, and which denticle types are the best for drag-reduction and further design advances. this knowledge will enable better use of shark skin technology to make advanced design solutions that help to make a better and more environmentally friendly world. for example, one possible use of shark skin technology is the development of surface structures on airplanes or boats to reduce drag during movement and decrease fuel emissions. in addition to its scientific impact, this project has impact on the stem workforce by supporting principal investigators and trainees across a wide range of career stages and by providing a unique, much-needed accessible research training program for undergraduates with disabilities in interdisciplinary research. the shape and pattern of shark skin teeth, or denticles, has been refined over millions of years of evolution for functional improvements

in aquatic locomotion. this project addresses the evolutionary and developmental trajectories that have led to a vast **\*\*diversity\*\*** of shark skin denticle types with the goals of determining why sharks have different shaped denticles among and within species and what functional advantages these different denticle shapes might offer these animals. from an integrated developmental, genetic, and evolutionary framework, the project will investigate how denticles develop and what factors lead to changes in shape. the approach will include studies of embryonic denticle development from the level of single cell transcriptomics to phenotypes and function to learn what key genes are essential to the production of various denticle shapes in a range of shark species and how these shapes are achieved via developmental innovation. goals include understanding what shapes are most efficient for drag-reduction in both modern and extinct species to enable modeling and testing of new engineering designs to reduce drag in air- and water-borne vehicles and devices. combining 3d printing with engineering methods, new shark-inspired surface structures will be used to create a shift in design solutions for a changing and more environmentally friendly world. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: CIF: Single-Particle Measurements of Soot and Incandescing Aerosol

Awardee: Clemson University

Amount: \$427,895.00

Abstract: this community instruments and facilities (cif) award makes the single-particle soot photometer (sp2) at clemson university available to the broader atmospheric science community. the sp2 can be used to measure the mass of black carbon in individual aerosol particles suspended in air. in addition, the advanced capabilities of the sp2 allow direct measurement of black carbon mixing state, or the degree to which black carbon is mixed with other, non-incandescing chemical species, on a single-particle level. funds awarded for this project will provide support to keep the sp2 in a user-ready state for laboratory studies, airborne field studies, and ground-based field deployments. the sp2 will be requestable by the scientific user community and provided with support to make full use of the soot photometer data. this project also supports outreach activities to reach a broader scientific community, to garner public interest in science, and to increase **\*\*diversity\*\*** in science, technology, engineering and math (stem) disciplines. black carbon or soot is an important aerosol type found in the atmosphere which is generated from nearly every combustion process, including vehicle engines, factories, and forest or agricultural fires. soot aerosol is highly absorbing of sunlight, which makes it an important component to understanding local heating, micrometeorology, and long-range, long-term climate. broader access to the sp2 instrument has the potential to advance knowledge in several topics concerning atmospheric aerosol particles. this award will enhance the ability of the broader scientific community to use the sp2 instrument at clemson university through the atmospheric and geospace sciences facility and instrument request process. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Diverse Evolutionary Power of Nucleic Acid Libraries Carrying Different Information Content

Awardee: Foundation for Applied Molecular Evolution, Inc.

Amount: \$426,000.00

Abstract: with the support of the chemistry of life processes (clp) program in the division of chemistry, dr. elisa biondi of foundation for applied molecular evolution, inc. will study chemical systems that could have served as precursors to the replicating macromolecules, such as rna and dna, found on earth and other places where life could exist. the macromolecules that make up current life on earth are composed of only a small subset of all possible chemical building blocks. dr biondi aims to provide insights into how only a small subset of molecules evolved and persisted into the current macromolecular systems. using the power of in-vitro evolution (evolutionary experiments performed in the laboratory), dr. biondi's laboratory will characterize potential prebiotic systems to provide insights into how the information density in the system (the number of building blocks), information amount (the minimum length of the polymer needed to display minimal activity), and information **\*\*diversity\*\*** (the types of building blocks and/or chemical groups) affect the performance and persistence of potential prebiotic systems. this project will provide fundamental intelligence on the information density requirement for an evolving nucleic acid library and shed light on many fundamental questions regarding the limits and ways in which prebiotic molecular evolution took place on our planet or others. additionally, results from this project will provide precious information to the large community of scientists who make use of in-vitro evolution to develop molecular tools applied in fields such as biomedicine, diagnostics, genetic engineering, and bioremediation. dr. biondi's outreaching activities will focus mainly on encouraging undergraduates, especially women and underrepresented minorities, to pursue stem careers. moreover, dr. biondi will participate in focus groups centered on the issue of women in science and will continue her virtual encounters with 3rd to 5th grade students to introduce them to astrobiology and general sciences. this project

will investigate what types of nucleic acid chemical systems are more suited for evolution towards catalytic functions and might have served as precursors of contemporary catalysts. the work will compare laboratory in-vitro evolution of nucleic acid libraries with different information density using biochemistry tools and high-throughput sequencing data. the chemical **diversity** of nucleic acid libraries will be adjusted with the artificially expanded genetic information system (aegis), developed in dr. biondi's laboratory. first, three parallel in-vitro selections of rna-cleaving dnazymes able to cut an rna substrate will be performed. the starting libraries will include a 25n random region and primer binding sites (pbs) composed of either standard or aegis dna, flanked by standard dna. a third selection will use libraries with a standard 25n region, but aegis in the pbs, which have been shown at fflame to improve self-pairing and yield cleaner pcrs. with this method, by removing some laboratory biases that have taunted the field for decades, it is expected that the work will not only improve the output of selection experiments, but also to gain extra insights into sequence-based fitness evolution previously 'buried' under techniques biases. in the next phase, initial experiments will be repeated with starting libraries carrying 19, 30, 40, and up to 45 random positions. these analyses will provide another level of information once biochemical and high throughput sequencing results for each selection will be compared: it is expected that not only will libraries with different information content evolve and explore the sequence space differently, but that a length difference in sequence options will also provide different evolutionary routes. further, outputs of selections performed with libraries carrying different types of modifications inside the random region, primer binding sites, or 5' and 3' ends of the molecules will be compared, with the goal of obtaining a comprehensive view of which groups and which combination of molecules have the best fitness towards a specific function. metrics for selection comparison will include number of cycles required to achieve function, catalysis parameters ( $k_{obs}$ ,  $k_m$ ,  $k_{cat}$ , turnover rates), and sequence fitness and enrichment values. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research:SWIFT:Ultra Wideband Flexible MIMO Radios for Energy Efficient Secure Spectrum Sharing

Awardee: Florida International University

Amount: \$425,000.00

Abstract: worldwide growth in wireless links, navigation, automation, internet of things (iot), and mobile healthcare has challenged spectrum access. in parallel, we are witnessing rapid advances in augmented reality/virtual reality (ar/vr), autonomous driving and vehicle-to-vehicle communications (v2v). further, increased adaptation of unmanned aerial vehicles (uav) may require large swaths of bandwidth and high data rates. indeed, the **\*\*diversity\*\*** of radio spectrum utilization is quickly growing. however, existing wireless networks may no longer be able to keep pace with these technologies, implying a need for new rhythms and targeted innovations. concurrently, security protocols must be adapted to avoid eavesdropping and man-in-the-middle (mitm) attacks. coexistence of active and passive spectrum utilization is another challenge. to address the aforementioned challenges, and to circumvent radio spectrum scarcity, this research brings forward innovations and features to significantly advance next generation wireless networks. among them: 1) increased throughput using robust spectrum sensing and slicing of legacy frequency bands by identifying gray and white spaces/gaps across the available electromagnetic spectrum; 2) frequency independent and high isolation antenna feeds and rf cancellers to enable spectrum co-existence; 3) wideband autonomous multiple-input-multiple output (mimo) transceivers using flex radio architectures to maximize overall spectral efficiency; 4) significant hardware reduction via multiplexing; and 5) resilience against man-in-the-middle attacks via artificial intelligence (ai) techniques. this project will also foster workforce development in the rapidly growing area of wireless engineering. curriculum enhancements are proposed to integrate new technologies on spectrum awareness, wireless security, and cross layer rf transceiver architectures. further, new degrees and

new curricula in wireless and iot technologies will be leveraged to promote stem outreach programs and coordinate outreach activities. the latter will be aimed at recruiting larger cohorts of undergraduates and k-12 students from the local miami-dade and broward counties to be trained in wireless engineering. examples of outreach programs to be leveraged include engineers on wheels, engineering expo, enlace (engaging latino communities for education), and the miami prep (positive youth preparedness) programs. the proposed research aims to develop next generation flexible and secure wireless networking with adaptive rf front ends and back-end cross-layer algorithms that enable spectrum efficiency and high throughput via novel relay architectures, all with end user protection in mind. namely, a new class of low cost and low power secure mimo transceivers with >100 db transmit/receive isolation are proposed along with flexible radio architectures. the following innovations are proposed: 1) ai-based effective spectrum utilization and/or coexistence, 2) innovative transmitter and receiver technologies through cross-layer design, and 3) improved security by detecting man-in-the-middle attacks and other eavesdroppers. notably, the transformative nature of the proposed research stems from the introduced novelties to overcome challenges in developing low-power and low-cost flexible radio architectures and rf electronics with secure data relays to provide resilience for man-in-the-middle attacks. to accomplish the proposed goals, a strong background is required in the following areas: rf front/back-end hardware, mathematical network modeling, propagation, optimization, control, queuing, stochastic analysis, and legacy system operation integrated through the following thrusts: 1) rf reconfigurability and spectrum aggregation to support users with decoupled phy/mac protocols, 2) adaptive flexradio wireless networks with increased throughput and protection using high performance phy/mac layer algorithm, 3) rf self-interference cancellation for spectrum co-existence, and 4) ai-based models for security and privacy. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: COLLABORATIVE RESEARCH: 21 cm Reionization Science with the MWA

Awardee: University of Washington

Amount: \$424,878.00

Abstract: the epoch of reionization (eor) is the period of time in the early universe when it is thought that the first stars and galaxies formed. understanding the physics of galaxy formation and feedback during the eor is one of the key goals of modern cosmology and astrophysics. observations of neutral hydrogen in the early universe have the potential to revolutionize our understanding of these first stars and galaxies. this work will improve data analysis with the murchison widefield array telescope so that researchers can make significantly better detections of such faint signals, making the observations much more useful and providing a tool for researchers engaged in similar projects. in addition, this work will continue and expand the initiative to provide research experiences for non-traditional undergraduates. undergraduate research is an essential component in preparing students both for graduate school and for positions in the broader stem workforce. providing this kind of research experience to non-traditional undergraduate students will enable more of them to go on to graduate school, increasing the **diversity** of the broader stem community. this award supports the continued work of a successful eor analysis team. over the past four years innovations by the us imaging power spectrum (ps) team have driven the field forward and have led to the deepest eor ps limits in the world. the investigators will make the next steps needed to reduce the limits by another order of magnitude with murchison widefield array (mwa) data. specifically, this work will make improvements in ps analyses with the mwa that will lower limits on the signal strength by an order of magnitude, making deep cuts into the possible parameter space for eor models. this research will be invaluable for the entire 21 cm community. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: IUCRC Phase II: Washington State University: Center for Bioplastics and Biocomposites [CB2]

Awardee: Washington State University

Amount: \$422,995.00

Abstract: the center for bioplastics and biocomposites (cb2) at iowa state university (isu), university of georgia (uga), washington state university (wsu), and north dakota state university (ndsu) seeks to develop and build on an industry/university cooperative research center (i/ucrc) that focuses on bioplastics and biocomposites. the mission of cb2 is to develop fundamental knowledge related to bioplastics and biocomposites, to disseminate research-based findings to industry to promote sustainability, and to educate future scientists and engineers. as such, there is an expressed industrial interest in leveraging research efforts to accelerate systematic development of standardized material and processing data for these novel plastics and composites. the center focusses on the development of jobs in the area of sustainable manufacturing and the conversion of agricultural and woody crops to bio-based materials that contribute to job creation in the united states. the center also strives to support education and **\*\*diversity\*\*** through engagement of undergraduate and graduate students in research on sustainable materials. the goal of cb2 is to improve the basic knowledge of synthesis, processing, properties, and compounding of bioplastic and biocomposite materials, to develop reliable materials characteristics data for industrial partners, and to support large-scale industrial implementation of renewable materials. the vision of the center is to develop knowledge that will facilitate the production of an array of high-value products, including plastics, coatings, adhesives, and composites, from renewable feedstocks. the materials are compatible with current industrial manufacturing systems and promote rural development as well as national growth. the goals of the phase ii are fourfold: 1) expand the knowledge and develop the science for recycling and end of life treatment of sustainable materials, in particular as they are mixed with petrochemical plastics; 2) expand membership by engaging new companies that have expressed a need for recycling and end of life treatment; 3) develop fundamental knowledge on sustainable materials; 4) prepare students to join the workforce equipped with the knowledge and

skills required by industry. the team of researchers includes experts in the fields of polymer processing, polymer chemistry, materials science, and crop utilization. wsu's research focuses on utilizing industry-relevant technology platforms to develop bio-based composites, coatings and adhesives, and polymers for various industry applications, as well as to recycle bio-based composite materials. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Awardee: Society for Personality and Social Psychology

Amount: \$421,165.00

Abstract: theory, methodology, and statistics in support of research in social and personality psychology has grown in complexity over the past three decades. these scientific advances are partly due to increasingly connected and diverse academic and professional networks among faculty. this project supports the continuation and extension of summer institutes in social and personality psychology (sispp). graduate students from social psychology and personality graduate training programs attend the advanced two-week intensive training program, led by renowned scholars and teachers in the field. training at this level helps to advance these fields of science and supports the production of important innovations. the institute also focuses on broadening the participation of graduate students who may be from groups historically and currently marginalized in these fields and who may not have intensive access to scholars in multiple subfields of their interest. evaluation of the previous training institutes (supported by nsf) reveals that graduate students who participate are successful in obtaining academic positions, peer-reviewed publications and funding for their research. affording graduate students with cutting-edge theoretical and methodological training enhances their ability to participate in interdisciplinary and international collaborations, which are increasingly important across all of science. scheduled every two years,

sispp provides an opportunity for approximately 100 advanced graduate students in social and personality psychology ph.d. programs to obtain intensive experience and instruction in cutting-edge theories, research, and methods. because graduate programs offer strengths in different areas, preference for attendance is given to students whose home institution does not offer strengths in the topics covered during a particular summer institute. sispp has been successful in fostering **\*\*diversity\*\*** in the field, both in promoting the careers of members of historically underrepresented groups and in enhancing the graduate training of students from programs with different emphases and resources. sispp has been successful in fostering research collaboration and communication networks among individuals from different laboratories, universities, regions, and nations, and creating a collaborative scholarly community for a new generation of researchers. the diversifying experiences enabled by sispp are critical for fostering creativity, innovation, and flexible scientific practices, and for expanding the scientific potential for social and personality psychology to support solutions to important societal challenges. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Digitization TCN: Collaborative Research: Bringing Asia to digital life: mobilizing underrepresented Asian herbarium collections in the US to propel biodiversity discovery

Awardee: Regents of the University of Michigan - Ann Arbor

Amount: \$420,761.00

Abstract: Asia is the largest continent on earth, and includes the world's tallest mountains, lowest landscapes, and habitats ranging from arctic tundra to tropical rainforests and mangroves to deserts. The plants of this region are incredibly diverse in their identities and functions. More than one-third of the world's 350,000 plant species grow in Asia and include tiny alpine cushion plants, medicinal herbs, ancient crops, and some of the planet's tallest rainforest trees. But documentation of this **diversity** remains inaccessible and research about it is difficult because most herbarium specimens of Asian plants have not been digitized. The All Asia Thematic Collections Network (TCN) will mobilize online 15 million specimens of Asian plants currently housed in the US and around the world. The project will especially focus on digitizing specimens from the unique and critically endangered bio**diversity** hotspots of Southeast Asia and the Himalaya-Hengduan region. These mobilized digital data will accelerate research to conserve endangered plant species and understand the interacting effects of evolution and global environmental change on plant species **diversity**. The project will apply state-of-the-art informatics tools and high-throughput digitization methods to efficiently and affordably digitize an unprecedented number of herbarium collections. This effort will connect and build long-lasting relationships among 25 large and small consortium institutions in the U.S., Europe, and Asia. The focal areas from which specimens will be digitized encompass five bio**diversity** hotspots that include ~20% of the world's vascular plant flora and historically spanned 3 million km<sup>2</sup> of primary vegetation that now covers less than 300,000 km<sup>2</sup>. Fundamental bio**diversity** data for these bio**diversity** hotspots are lacking, along with the necessary baselines required to characterize species' identity, range, and responses to ongoing climatic change. The overall goals of the All Asia TCN are to rapidly digitize herbarium specimens of Asian plants to advance bio**diversity** discovery and provide critical baseline assessments

essential for establishing floristic change in the anthropocene. the project will accomplish this by (1) digitizing 3 million asian vascular plant specimens from u.s. herbaria; (2) developing and applying novel informatics tools and high-throughput digitization methods to massively scale herbarium digitization; (3) aggregating and mobilizing the digitized records from the project with those by international partners in china, france, the netherlands, and russia to establish a single online all asia portal of ca. 15 million specimens; and (4) enhancing opportunities for early career learners in science, technology, engineering, and mathematics by stimulating synergies between bio\*\*diversity\*\* and computer scientists who will use design thinking principles to create real-world informatics solutions to bio\*\*diversity\*\* challenges. to stimulate curiosity in plant \*\*diversity\*\* and botanical exploration among the general public, the consortium members will host several asia-themed notes from nature virtual expeditions to facilitate additional specimen digitization by citizen-scientists. digitized specimen data mobilized through this project will be shared and made available through idigbio.org. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: REU Site: Sustainable Resilient Transportation Systems

Awardee: University of Delaware

Amount: \$420,383.00

Abstract: climate change is one of the major challenges that the u.s. faces in the 21st century. carbon emissions, as a major catalyst, are in great part a result of construction, maintenance, and operation of transportation systems. with support from the nsf division of engineering education and centers, this award establishes the reu site in sustainable resilient transportation systems at the university of delaware which will contribute to the state-of-the-art technologies and design methodologies with a potential to reduce carbon emissions and, consequently, help address climate

change. the site will host a diverse cohort of undergraduate researchers who will engage in interdisciplinary research programs in electric and autonomous vehicles; green construction materials and structures; and resilient infrastructure. by enabling low-carbon footprint transportation systems, the reu site contributes towards improved global economic prosperity, the safety of our planet's residents, and future development. training provided at the reu site will help develop a diverse stem workforce capable of tackling the complex engineering challenges of the 21st century, improving the u.s. competitiveness at the global level. this unique program provides students with research experiences in sustainable resilient transportation systems; develops students' experimental, quantitative analysis, and communication skills; fosters student appreciation of interdisciplinary collaborations, the pursuit of graduate degrees and careers in transportation-related fields; and increases the **\*\*diversity\*\*** of the transportation workforce. this is accomplished by the students participating in individual and cohort experiences. individual experiences will promote students' transition from dependent to independent researcher status in their laboratory by engaging students in personalized mentoring with reu site faculty advisors. cohort experiences are designed to strengthen students' intellectual focus in sustainable resilient transportation systems, support the development of students' research skills, and encourage student-student communication and collaboration. it is anticipated that this work will contribute to the development of more diverse engineering programs for students underrepresented in stem as well as provide opportunities for students that have limited access to research experiences. this underserved population presents a significant potential benefit to society in areas in which innovation and creativity are most needed. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: SWIFT: Cognitive-IoV with Simultaneous Sensing and Communications via Dynamic RF Front End

Awardee: University of Minnesota-Twin Cities

Amount: \$420,000.00

Abstract: future transportation is promising safer and more efficient traveling via connected intelligence among vehicles as well as with the transportation infrastructure. at the same time, travelers can also be relieved from tedious driving and use vehicles as offices or entertainment rooms on the move. essential to all these is a reliable and resilient internet of vehicles (ioV). given the unique transportation environment, a satisfactorily functioning ioV is confronted with many challenges. for example, data services for transportation safety/efficiency and/or traveler convenience/comfort are often very sensitive to delays and require large bandwidth. the vehicular environments are also filled with various communication services as well as active sensing devices, which can potentially cause interferences to each other. in addition, the high mobility inherent to transportation and fluctuation of the transportation information exchange depending on the specific traffic scenario can both lead to fast-changing and possibly unpredictable dynamics. to address these challenges, this project organizes collaborative efforts to enhance spectrum utilization, sharing and management in ioV. the project will promote the interactions among multi-disciplinary experts such as electromagnetic waves, electronics, signal processing and wireless communications to create wireless innovations at different network layers. the developed technologies will provide

valuable tools for foundational science and engineering research and promote societal embracing of the emergent cognitive iov technologies. the project also has an integrated education plan that aims to prepare the workforce to address future challenges of spectrum utilization and wireless communications, while promoting and embracing **\*\*diversity\*\*** in science and engineering. this project aims to develop a cognitive iov framework with simultaneous sensing and communications via a novel dynamic rf front end. targeting the aforementioned challenges, the proposed iov research has three distinctive features. first, the proposed research is centered at simultaneous communications and sensing. based on a dynamic rf front end that is innovatively designed to facilitate full duplex modes, communications and simultaneous monitoring of multiple spectrum bands with tunable granularity become possible. secondly, the resultant iov framework is cognitive in two counts: i) cognitive in the spectrum environment - the spectrum sensing information from devices equipped with the dynamic rf front end is used to develop algorithms to learn and track the spatiotemporal radio tomography with quantifiable uncertainty; and ii) cognitive in the physical environment - with judiciously designed waveforms that enable simultaneous communications and active physical environment sensing, the acquired information will be leveraged to enhance communications. last but not least, the proposed cognitive iov framework is dynamics-ready via hardware, architecture, and algorithm design: the dynamic rf front end boasts real-time tuning and control capability, the network architecture incorporates unmanned aerial vehicles (uav) to mobilize on-demand support for transportation/traveler data service hotspots, and reinforcement learning algorithms developed to achieve closed-loop control and management of spectrum resources will remain robust when the dynamics are unknown or unpredictable. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: GP-IN: Families and University Together as a Unit for Research and Education (FUTURE):

## Connecting Hispanic Families to Geosciences Through Community Informal Learning Network

Awardee: The University of Texas Rio Grande Valley

Amount: \$419,996.00

Abstract: this award is funded in whole or in part under the american rescue plan act of 2021 (public law 117-2). a strong and diversified next generation geoscience workforce will play a critical role in solving crucial global threats (water, energy, natural hazards, and food) under climate stresses in the coming decades. in the u.s., the geoscience workforce has the least ethnic **\*\*diversity\*\*** compared to other stem fields (e.g., ~3% hispanics). national academies press states that minority serving institutions are america's under-utilized resource for strengthening the stem workforce for the near future. the university of texas-rio grande valley (utrgv), as the nation's second largest hispanic serving institution (with ~32,000 students and ~90% hispanic), and its location at the u.s.-mexico border, make it an ideal hub for training the future hispanic geoscience workforce. the future project integrates the hispanic culture into an informal geoscience and stem learning pathway through a family-centered model to address the challenge of enhancing hispanic participation in stem. a family-centered learning framework will help families understand one of the most critical elements in their lives ? water supply/resources? and its relationship to the geoscience/earth environment. with the experience gained in a previous geopaths project, the project team aims to expand and scale up the established platform and infrastructure of its existing program transforming the traditional geoscience learning ecosystems (gles) while nurturing the hispanic geoscience workforce in a way that can be expanded to other minority serving institutions. the future project will explore how the family can be placed at the center of informal stem learning and be the basis for understanding a geoscience issue ? how water works;? i.e., the water cycle with humans at the center, and the activities/link to earth environment (i.e., mining and agriculture in texas). the future project has four objectives: (1) establish an informal learning network with a water and earth-environmental science theme at communities; (2) change hispanic families' (parents and children) perspectives towards geosciences careers; (3) recruit students into geoscience through a

developed network and (4) provide a channel into geoscience education and career paths for local junior/senior high school and 2-year college students. the project offers activities focused on water, soil, rocks and minerals, geoscience and their relationship to rio grande valley's history and economics (oil/gas mining and agriculture). future's innovative approach will test how informal learning networks between the local community and educational institutions can transform gle for individuals from groups that have historically been underrepresented in stem. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: RCN: Expanding the History of Science, Technology, Environment, and Medicine: The United States and its Regional Neighbors

Awardee: University of Maryland, College Park

Amount: \$419,209.00

Abstract: science has often been understood as a universal language, involving conversations across all parts of the planet. however, as recent controversies regarding vaccination and climate change remind us, not everyone understands science in the same way. recent research on science, technology, environment, and medicine is addressing this issue by looking at how diverse publics engage with and apply science. they are also analyzing how these disparate publics influence scientific innovation. still, most of this research focuses on the united states and europe. this project provides a more comprehensive view of how science works by examining scientific innovation and application in latin america and the caribbean and the relation of science in the region to other sites. by sponsoring a website, workshops, and publications, the project will produce new resources for teachers and researchers, providing access to cutting edge studies of science in latin america and the caribbean. it will also train a new generation of graduate students in the history of science to conduct research on latin america and the caribbean and to incorporate the region into their

courses. this research coordination network project brings together senior and established researchers and graduate students to take stock of the vibrant and burgeoning fields of science, technology, environment, and medicine in latin america and the caribbean. our network will secure ties among researchers in north and south america and unify discussions taking place with a variety of academic societies and organizations. it will produce publications that make this research available to those who are not specialists in the region. the ethnic and racial **\*\*diversity\*\*** of latin america and the existence of creolized indigenous and afro-descendant knowledge practices make it an excellent place for advancing knowledge of worldviews that challenge or coexist with scientific rationalities. project participants will include graduate students in the history of science and provide them with in-depth training and mentoring on latin america and the caribbean--training that is not readily available in the majority of history of science graduate programs. k-16 teachers will gain access to bibliographies, lesson plans, essays, and collections of syllabi that allow them to cover a broader range of scientific endeavors and of a more diverse community of scientists. their students will in turn incorporate and reproduce more complete and complex representations of how science functions globally. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: A Robust Temporal Framework for the Paleoproterozoic Crash of Atmospheric Oxygen

Awardee: University of Wisconsin-Madison

Amount: \$419,135.00

Abstract: the protracted rise of atmospheric oxygen has important implications for the trajectory of biological evolution and global nutrient cycling. this work will test ties between large-scale environmental changes and biotic macroevolution in the paleoproterozoic. investigators will obtain age constraints for sediments within the onega basin of russia and the lastoursville basin of gabon

to evaluate the synchronicity of carbon burial episodes potentially associated with an overshoot and crash of atmospheric oxygen levels in the paleoproterozoic era. the geochemical constraints they obtain will allow to critically evaluate the synchronicity and extent of marine conditions and oxygen levels at the termination of what may have been the most dramatic disturbance to the carbon cycle in earth history. these efforts will be paired with a science video-logging series, terralingua: reading the rock record, which will be broadly disseminated through the travelinggeologist platform on social media, reaching a total audience of over one million globally. this series will provide content highlighting the variety of tasks that geoscientists complete, including field work in russia with a team of international collaborators, geochemistry laboratory and mass spectrometry work, and will also cover common barriers to entry in the geosciences and academia. the goal of this project is to improve our understanding of the trajectory of atmospheric oxygen during the ~2.3-2.0 ga lomagundi-jatuli (lj) positive carbon isotope excursion and the subsequent shunga negative carbon isotope excursion in the onega basin of russia and the lastoursville basin of gabon. the proposed research will address: 1) how did oxidative weathering vary during these carbon isotope excursions? 2) do the end-lj and the shunga event occur synchronously in the onega and lastoursville basins? the petrologic, isotopic and temporal constraints to be determined will permit global correlations and shed novel insights into the rise of oxidative weathering and global carbon cycling at this critical juncture. this will support education, outreach, and **\*\*diversity\*\*** initiatives through the training of a phd student and postdoc and the production of a broadly disseminated videologging series (terralingua: reading the rock record) focused on geochemistry as well as promoting inclusivity in field- and laboratory-based geoscience fields and more broadly within academia. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: MRI: Acquisition of a controllable pulse transcranial magnetic stimulator with robotic

positioning and integrated EEG / EMG for engineering and neuroscience research and education

Awardee: Northeastern University

Amount: \$417,913.00

Abstract: understanding the brain's role in behaviors such as movement, cognition and emotion is paramount to progress in science and engineering, and to advancing improvements in health and wellness. invasive approaches in animals cannot be readily adapted to humans, creating a technological barrier to causal study of the brain in awake behaving humans. one promising approach in humans, transcranial magnetic stimulation, uses magnetic pulses to noninvasively and safely modulate brain activity. however, stimulators modulate brain cells (neurons) indiscriminately, which prevents studying how distinct neurons drive behavior. this award will facilitate the acquisition of a cutting-edge stimulator that allows scientists to modulate specific neuron populations in the brain. the system includes an integrated positioning robot for precise localization and recording devices that read physiological signals from the brain or muscles to objectively quantify the effects on different neural populations and behavior. this instrumentation will enable discoveries that will catalyze new research in the study of brain and behavior. crucially, the instrumentation paired with the proposed education plan will create unique training opportunities for students in stem and health science, lowering the barrier of entry for underrepresented students, including persons of color and women. the project leverages northeastern university's experiential education model and various **\*\*diversity\*\***/inclusion initiatives to support research by diverse (under)graduate and k-12 students and teachers. the project proposes the acquisition of a controllable-pulse transcranial magnetic stimulator capable of differentially modulating specific neural populations in the human brain, with integrated robotic positioning and electroencephalography and electromyography recording. this instrumentation will be the only such system in the northeastern us. as part of the northeastern university non-invasive brain stimulation center, it will enable unprecedented basic science research into human neurophysiology and brain-behavior relationships, and significant advances in fundamental engineering research in stimulator development, automated robotic positioning,

stimulation-induced artifact removal in physiological recordings, closed-loop stimulation, and artificial intelligence / machine learning algorithms. allowing researchers to control stimulus waveforms and to differentially activate distinct neural populations will enable a scientific scope of work that will transcend multiple disciplines including motor and affective neuroscience, cognition, memory, development, aging, and biophysical modeling of brain physiology. the proposed **\*\*diversity\*\*** and education plan enabled by this instrument will lower barriers for underrepresented minority students to engage in cutting-edge experiential stem education. the project's impact will be profound on science and technology innovation, as well as in training a new, diverse, interdisciplinary workforce to drive this field forward. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Does Cytonuclear Coevolution Drive Reproductive Isolation?  
Dissecting the Architecture of Genetic Incompatibility Across a Species Range

Awardee: University of Virginia Main Campus

Amount: \$416,757.00

Abstract: the natural world exhibits a vast array of bio**\*\*diversity\*\*** which ensures the stability of ecosystems, the services they provide, and has intrinsic aesthetic value. individual species are critical elements of this bio**\*\*diversity\*\*** and understanding how new species form is key to ensuring maintenance of **\*\*diversity\*\***. interactions between the nuclear genome and organelle (mitochondria and chloroplast) genomes underlie key processes including respiration and photosynthesis. these interactions are an underappreciated and yet potentially powerful driver of the earliest stages of speciation. the planned research will investigate the contribution of intergenomic interactions to incompatibility between populations of a species. the research will use state-of-the art techniques to identify the genomic basis of incompatibility between the nuclear and organelle genomes and

determine the ability of such incompatibility to maintain genetic divergence and facilitate speciation in a contact zone. the project will also introduce undergraduate students and high-school and community college teachers to core ideas about species formation and evolution through hands-on experience with the newest genomic sequencing technologies in a novel course-based lab module and workshop. finally, the project will provide training at the undergraduate, graduate, and post-graduate level. interactions between cytoplasmic and nuclear gene products are expected to drive intergenomic coevolution, leading to the potential for genetic incompatibility and reproductive isolation between populations with divergent cytoplasmic genomes. while such cytonuclear incompatibility (cni) has been posited to be among the earliest reproductive barriers to develop during speciation, our understanding of the dynamics of cni at the early stages of speciation remains limited, particularly for plastid-driven speciation. the research will examine the dynamics of plastid driven cni in *campanula americana*, creating a powerful set of genomic resources, characterizing variation in the genetic architecture of cni across lineages, and leveraging a natural contact zone to evaluate whether exposure to selection alters the genetic architecture of cni relative to allopatry. together, these data will provide insight into the evolutionary dynamics of plastid-nuclear incompatibility and how these dynamics may drive the early stages of speciation. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Chemical imaging of sheets, surfaces, and interfaces

Awardee: University of Tennessee Knoxville

Amount: \$416,184.00

Abstract: non-technical summary with this project, which is supported by the solid state and materials chemistry program in the division of materials research, professor janice musfeldt and her research group will explore the properties of material sheets, and material surfaces and interfaces

using near field-infrared spectroscopy, and will invest in the education of a diverse group of young people at the university of tennessee. both initiatives will advance the use of chemical imaging spectroscopies at synchrotron facilities and contribute to important societal values and outcomes. a variety of material systems will be imaged including van der waals, ferroic, and catalytic materials. these material sheets and textures are small in size - well below the diffraction limit of traditional infrared spectroscopies - which is why near-field imaging approaches such as those employed in this project have the potential to be transformative, also in unraveling important structure-property relationships. a broad range of educational, outreach, and service activities will also take place under the auspices of this national science foundation-funded program, especially in the areas of **\*\*diversity\*\***, conference and workshop organization, and service to various national laboratories.

technical summary    the research, which is supported by the solid state and materials chemistry program in the division of materials research, employs synchrotron-based near-field infrared spectroscopy to image a variety of materials with different functionalities. the focus is on van der waals, ferroic, and catalytic materials, as well as the structure-property relationships that can be unraveled in these systems. the goals are to: (i) explore symmetry and properties of magnetic and heavy chalcogenides and halides in the ultrathin limit, (ii) reveal interface dynamics in unusual settings such as at ferroelastic and ferroelectric domain walls, (iii) untangle chemical bonding heterogeneities and their relationship with catalytic behavior, and (iv) understand how these effects can be enhanced and controlled. what brings these efforts together is an overall interest in imaging heterogeneity in quantum materials and the opportunity to explore completely new types of light-matter interactions. findings from this program will advance the development of theoretical approaches and of energy-related applications. this program also supports the interdisciplinary education of a diverse group of young researchers for future employment in academics, government laboratories, and industry in the area of advanced materials.    this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Redefining the footprint of deep ocean methane seepage for benthic ecosystems

Awardee: University of California-Los Angeles

Amount: \$415,399.00

Abstract: this research examines the role of deep-sea organisms in determining the fate and footprint of methane, a potent greenhouse gas, on pacific continental margins. the investigators are evaluating the deep ocean methanosphere defined by the microbial communities that consume methane and the animals that directly feed on or form symbioses with methane-consuming microbes. they are also investigating animal communities that gain energy indirectly from methane, as well as those that take advantage of carbonate rocks, the physical manifestation of methane consumption in seafloor sediments. the study of methane seeps in the deep waters of both alaska (4400-5500 meters) and southern california (450-1040 meters) is enabling comparisons of the methanosphere under different food-limitation and oxygen regimes. by applying diverse chemical, isotopic, microscopy, and genetic-based analyses to seep microbes and fauna, this study is advancing understanding of the contribution of methane to deep-sea bio\*\*diversity\*\* and ecosystem function, information that can inform management and conservation actions in us waters. in addition

to training for graduate and undergraduate students at their home institutions, the investigators are collaborating with the alaska native science and engineering program (ansep). they are recruiting alaskan undergraduates to participate in the research, contributing to ansep's online resources that promote interaction between scientists and middle and high school students, and participating in ansep's annual residential career exploration in marine science programs to engage middle school students in learning about deep-sea ecosystems and the variety of career pathways available in marine related fields.

microbial production and consumption of methane is dynamic and widespread along continental margins, and some animals within deep-sea methane seeps rely on the oxidation and sequestration of methane for nutrition. at the same time, understanding of methane-dependent processes and symbioses in the deep-sea environment is still rudimentary. the goals of this study are to 1) examine the **diversity** of animals involved in methane-based symbioses and heterotrophic consumption of methane-oxidizing microbes and how these symbioses extend the periphery of seeps, contributing to non-seep, continental slope food webs; and 2) determine whether carbonates on the seep periphery sustain active methanotrophic microbial assemblages, providing a localized food source or chemical fuel for thiotrophic symbioses, via anaerobic oxidation of methane, or free-living, sulfide-oxidizing bacteria consumed by animals. the investigators are addressing these goals by surveying, sampling, and characterizing microbes, water, sediments, carbonates and animals at a deep seep site on the aleutian margin and a shallow site off southern california. shipboard experiments and laboratory analyses are using molecular, isotopic, geochemical, and radiotracer tools to understand transfer of methane-sourced carbon from aerobic methanotrophs under multiple oxygen levels, pressures, and photosynthetic food inputs. this approach offers a wide lens by which to examine the methane seep footprint, allow reinterpretation of past observations, and identify new scientific areas for future study. improved characterization of the deep continental margin methanosphere informs climate science, bio**diversity** conservation, and resource management. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts

review criteria.

Title: CCSS: Online Learning for IoT Monitoring and Management

Awardee: University of Minnesota-Twin Cities

Amount: \$415,000.00

Abstract: at the core of several emerging technological advances lies the notion of internet-of-things (iot). conceptually, iot is envisioned as an intelligent network infrastructure with a huge number of ubiquitous smart devices present in diverse application domains such as smart buildings, group and personalized healthcare, as well as self-driving connected vehicles, to name a few. today, a number of iot applications have already improved many aspects of daily life. however, critical challenges need to be addressed before embracing the full potential of iot. this in turn calls for innovative machine learning approaches that account for scalability, heterogeneity, adaptivity, and robustness to unpredictable uncertainties -- what are the central challenges facing the emerging iot monitoring and management tasks. novel algorithms and their performance need to leverage recent advances in data science, optimization, statistical signal processing, communications, and networking. in addition to markedly influencing future iot modules, insights gained from this project's learning and inference will also cross-fertilize benefits to a gamut of additional domains, including smart grids, smart cities, and self-driving vehicles. at a broader scale, the developed technologies will provide valuable tools for foundational science and engineering research, and advocate societal embracing of the emergent iot technologies. broader impact will be further effected by the integration of research with an educational plan designed to train the new cadre of next-generation of iot professionals, as well as foster cross-pollination of academic research to industry needs, while promoting and embracing **\*\*diversity\*\*** in science and engineering. to address the core iot challenges, this project puts forth foundational tools for real-time interactive function learning using an ensemble of experts. learning algorithms will be developed with adaptivity and quantifiable

performance even in environments with unpredictable dynamics, but also with ability to scale in terms of i) the huge number of "things" in iot; ii) the high-dimensional feature vectors involved in sophisticated learning tasks; and iii) the massive data collected, processed, and exchanged over the iot graph ? what is desired for iot monitoring. scalability, adaptivity, and robustness benefits in learning nonlinear functions will be further permeated to interactive black-box bayesian optimization, and reinforcement learning with an ensemble of experts -- merits that will boost performance in open- and closed-loop iot management. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Toward lifelike synthetic cells via engineered control of DNA replication

Awardee: University of New Mexico

Amount: \$414,071.00

Abstract: the ability of cells to reliably replicate and maintain genomic information is a key facet of life. recapitulating these mechanisms is a critical step towards the development of autonomous synthetic cells that exhibit self-replication and stable propagation of their genetic information. to that end, this project creates a new synthetic mechanism for dna replication control in synthetic cells that will open the door for new applications in biomedicine and biotechnology. this project carries out an integrated social science investigation into the current regulatory framework surrounding engineered synthetic cell technologies. this project also provides educational and technical training aimed at increasing the number and **\*\*diversity\*\*** of undergraduates and graduates pursuing careers in synthetic cell research. public outreach is carried out in conjunction with local partners to increase public awareness of synthetic cell technologies. natural cells have evolved sophisticated mechanisms to control dna replication, to prevent the loss of critical genes while simultaneously

preventing runaway replication. analogous replication control mechanisms will be required for synthetic cells. while natural genome replication control systems are complex, plasmids provide a simple yet powerful and modular system for building synthetic replication control systems and modular genomes for synthetic cells. this project addresses the broad challenge of engineering dna replication control mechanisms for synthetic cell systems. rna engineering techniques are used to create modular and programmable synthetic plasmid replication control systems that function in both cells and cell-like systems. this project also studies how dna replication can be utilized for novel biosensing applications. biocontainment applications are investigated through an integrated social science investigation. this award is co-funded by the systems and synthetic biology cluster in the division of molecular and cellular biosciences and the cellular and biochemical engineering program in the division of chemical, bioengineering, environmental and transport systems. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: CAREER: Evolutionary Disease Ecology- Can evolutionary responses to environmental change modify the biodiversity-disease relationship?

Awardee: SUNY at Binghamton

Amount: \$413,756.00

Abstract: understanding patterns of emerging infectious diseases is at the forefront of global interest. this research asks: "why are some communities more vulnerable to diseases than others?" to address this broad question, this work focuses on understanding how bio**\*\*diversity\*\*** influences

community disease risk. while many studies find that communities with higher bio\*\*diversity\*\* have lower disease risk, some studies show no effect of bio\*\*diversity\*\* on disease risk and others even find the opposite effect (i.e. communities with higher bio\*\*diversity\*\* have higher disease risk). overall, the idea that bio\*\*diversity\*\* can reduce disease risk is attractive because it suggests that protecting bio\*\*diversity\*\* has clear benefits to both nature and society. this research tests the central hypothesis that cryptic differences in population's responses to past conditions (i.e. evolutionary history) plays an important role in understanding when bio\*\*diversity\*\* will reduce disease risk. this career award will develop a summer research and outreach program that supports undergraduate artists, engineers, biologists, and educators and a 3rd grade citizen science training program. the bio\*\*diversity\*\*-disease (bdd) relationship has generated considerable attention as a theoretical framework for predicting community disease outcomes. yet, limited consensus on the generality of the bdd relationship has been reached leading to repeated calls to uncover factors shaping the magnitude and direction of the bdd relationship. this research tests the hypothesis that intraspecific host variation, generated by divergent evolutionary histories, plays a cryptic role in shaping the direction and magnitude of the bdd relationship. to this end, the research focuses on amphibian host-parasite interactions and takes advantage of an experimentally tractable group of focal wood frog populations that exhibit intraspecific variation in parasite susceptibility as a result of evolving in contrasting environments. the researchers will first, evaluate the contribution of intraspecific variation to shaping the bdd relationship by generating mesocosm communities that vary in amphibian host species \*\*diversity\*\* and focal host intraspecific \*\*diversity\*\*. second, to integrate ecological context into our understanding of how intraspecific variation influences the bdd relationship, the researchers will conduct lab and mesocosm studies testing whether intraspecific variation in focal hosts can shape the bdd relationship by modifying (a) competitive, (b) predator-prey, or (c) host microbiota interactions. third, to complement the controlled experimental studies, the researchers will conduct a citizen-led field surveys to evaluate whether intraspecific variation modifies the bdd relationship in more complex natural ecosystems. towards this aim, the

researchers will develop a two-step integrated education-research program: (1) content development: researchers will design an interdisciplinary program where undergraduates work with local communication and education experts to develop a citizen training program. (2) implementation: citizens will complete training program and collect field data that contributes to the overarching research goals. collectively, this integration will facilitate citizen data collection efforts, diversify stem training and engagement, and broaden access to authentic research opportunities. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: MCA: Integrating immune system and microbiome function during amphibian development

Awardee: University of Colorado at Boulder

Amount: \$413,329.00

Abstract: microbial organisms, such as bacteria, often live in a symbiotic relationship with animals and provide beneficial functions that support health of the host animals. for many of these bacterial and animal symbiotic relationships, we know very little about their specific biology and what kinds of beneficial functions the symbiotic partners provide. like most vertebrate animals, amphibians have complex immune systems with innate and adaptive immune functions, however amphibians do not develop a fully capable immune system until after they metamorphose from the aquatic tadpole life stage. the investigator proposes a novel hypothesis postulating that the symbiotic skin bacteria on aquatic tadpoles provide protective defensive functions while the immune system is not yet mature. the project will test this idea using an experimental approach that will examine the immune system and bacterial symbionts of an amphibian during its development from the egg and tadpole stages through metamorphosis. the colorado boreal toad will be featured in this work, and it is locally endangered in the southern rocky mountains due to a fungal skin pathogen. this project will advance understanding of the ways in which boreal toads defend themselves against the pathogen which can

be helpful for conservation of the species. the investigator is a mid-career scientist who will work with a collaborator and mentor to expand learning how to apply immunology methods to amphibian disease research. the investigator is also dedicated to service in her position to support **\*\*diversity\*\***, equity and inclusion as the director of graduate studies in her unit. host-associated microbes provide a range of beneficial and necessary functions for their host organisms, yet the processes that drive the assembly of host-associated microbial communities is a significant knowledge gap. this project will study microbiome function on the skin of amphibians in order to examine the role of symbiotic microbes in pathogen defense and how that functioning changes during amphibian development. growing a complex immune system that is capable of targeting and ridding harmful pathogens takes significant developmental time, and most of the adaptive immune system of amphibians does not come online until after metamorphosis. this begs the question, how do larval, aquatic amphibians defend themselves against a sea of opportunistic pathogens prior to the full functioning of the immune system? this project will test the idea that larval amphibians assemble a symbiotic microbial community with pathogen defense as a primary function, the ?microbial surrogate defense system hypothesis?, prior to the maturation of the immune system. the investigator proposes a time-series experiment that will track the symbiotic skin bacteria and immune function during boreal toad development and conduct three pathogen challenge trials that will occur before, during, and after metamorphosis, respectively. the project will use both culture-dependent and sequencing tools to characterize the bacterial symbionts and immunogenomic and transcriptomic tools to characterize immune function. this project represents a first-time collaboration between the pi and a research partner who will provide expertise on amphibian immunogenetic tools as well as mentoring related to career advancement for the pi. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: HSI Implementation and Evaluation Project: Advancing the Reach and Scope of Supplemental Instruction

Awardee: North Park University

Amount: \$413,066.00

Abstract: with support from the improving undergraduate stem education: hispanic-serving institutions (hsi program), this track 2 project focuses on increasing stem student retention and success in entry-level courses at a hispanic serving institutions (hsi) by expanding and adapting supplemental instruction (si) to online learning environments. si is a peer-facilitated academic support program consisting of regularly scheduled out-of-class collaborative learning sessions. there is growing demand for well-trained stem professionals, but high rates of student attrition in introductory level science and engineering courses limit the number of stem degrees awarded. additionally, **diversity** and inclusion in stem fields remains a major concern, with students from traditionally underrepresented backgrounds earning stem degrees at levels well below rates of enrollment. si participation is a positive predictor of higher grades and student success in introductory stem courses, and interaction with si leaders of diverse backgrounds has been shown to further benefit underrepresented student groups in these classes. this project will expand face-to-face and online si offerings to make si more accessible and beneficial to a diverse group of stem students, including non-traditional and commuting students. in addition, the project will seek to expand si leadership opportunities to traditionally underrepresented student groups. the project aims to (1) determine the impact of the si program on student retention and success in introductory science courses, and (2) determine the effect of the si program on student's metacognition, affective components of learning, and positive attitudes toward stem education and stem careers. this multi-year project will employ a variety of quantitative and qualitative research methods over a period of three successive fall academic terms. findings will be compared among three student groups/ sets: those who attend required face-to-face si sessions, those who attend required online si sessions, and those for whom si session attendance is optional. the research will provide insight into

the effect of face-to-face and online si implementations on student success, particularly among non-traditional and commuter student populations to whom face-to-face si sessions may be less accessible. in addition, the project findings will contribute to best practices for successful adaptation of si to online learning environments. broader dissemination of the findings at national conferences and in peer-reviewed educational journals of respective stem fields will allow participants to share insights and innovations with the growing community of stem educators leveraging peer-facilitated learning models. the hsi program aims to enhance undergraduate stem education, broaden participation in stem, and build capacity at hsis. achieving these aims, given the diverse nature and context of the hsis, requires innovative approaches that incentivize institutional and community transformation and promote fundamental research (i) on engaged student learning, (ii) about what it takes to diversify and increase participation in stem effectively, and (iii) that improves our understanding of how to build institutional capacity at hsis. projects supported by the hsi program will also draw from these approaches to generate new knowledge on how to achieve these aims. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: REU Site: Research Experiences for Community College Students in Physics and Astronomy

Awardee: CUNY Queensborough Community College

Amount: \$412,659.00

Abstract: this award is funded in whole (or in part) under the american rescue plan act of 2021 (public law 117-2). this research experiences for undergraduates (reu) site at queensborough community college in new york city has a number of broader impacts that focus on providing research opportunities to undergraduates to help prepare them for future science, technology, engineering, and mathematics (stem) careers. the site focuses on providing research opportunities to students from community colleges who have had no prior research experience. the site has a

strong plan to recruit students from groups underrepresented in physics. the research projects proposed for the students to engage in are varied and reach across different physics and astronomy topics including black holes, biophysics, cosmic ray detection, x-ray spectroscopy, acoustics, and climate change. due to the **\*\*diversity\*\*** of the research topics offered the students have an opportunity to engage in research that excites them while mastering skills that can be applied to the academic journey in a number of ways. participants will have the opportunity to access and analyze big data using large national databases which will give them skills in understanding and applying large amounts of data. they will learn computational methods to create applications that can collect and manipulate data as well as run large simulations from basic equations that will predict physical outcomes. they will have the opportunity to physically build detectors and assist in collecting and analyzing data from experiments with partners all over new york. the reu site at queensborough community college provides opportunities to twelve undergraduate students at community colleges per year. one of the goals of the reu site is to prepare the students to be competitive for transfer to a four-year college in a stem discipline. in addition to participating in research with an experienced mentor, the students will engage in activities to ensure not only that their research stays on track but that they have an engaging collegial and scholarly experience. the skills of data handling and analysis, building and controlling equipment and computation methods can be applied to their academic path and many of their careers. a focus on scientific communication and collaboration will also be emphasized which is an essential skill for any stem student in all aspects of their journey. by the end of the program, every student will present the results of their work in a seminar talk. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: RoL: The intersection between cell fate decisions and phenotypic diversification in a rapidly radiating butterfly lineage

Awardee: George Washington University

Amount: \$410,662.00

Abstract: animal structures are made of combinations and arrangements of distinct cell types, the product of complex cell decision-making during development. but how do cells, which contain identical genetic information, decide their fate? this research addresses this fundamental biological question in a simple, yet spectacularly diverse animal structure?the color patterns on the wings of heliconius butterflies. although heliconius wing patterns are highly diverse, they are created by altering the distribution of just three cell types (red, black and yellow wing scales) across the wing surface. unlike in a complex organ, the cell decisions that create these patterns unfold on a flat canvas of non-migrating cells. this attribute greatly simplifies the process of understanding the interactions among genes and how these interactions change throughout development to create a specific pattern. this research capitalizes on this fact and emerging genomic tools to characterize the molecular decisions that determine how a developing wing cell becomes specified into one of the three different scale cell types. the project is strengthened by a 6-month internship program that targets traditionally underrepresented groups and offers an in-depth research experience and hands-on professional development. moreover, through partnerships with science museums, this project will create bilingual (english and spanish) experiential learning resources that harness the potential of butterflies to educate a variety of audiences (school children, teachers, and life-long learners) about genes, development, natural selection, and the role that interactions among them play in generating earth?s bio\*\*diversity\*\*. evolutionary processes constantly generate and rearrange specialized cell types, forging the morphological dimension of bio\*\*diversity\*\*. research is starting to connect changes in gene expression and open chromatin to cell fate decisions. however, this research has mostly focused on early embryonic development or on the developmental trajectories of complex organs in a few species. although powerful, these studies do not have an explicit goal of linking changes in cell fate decisions to phenotypic change. this research fills this important knowledge gap by characterizing the rules governing cell specification? from signals, to

reception, transduction, transcriptional activation, and fate determination during the critical developmental period when the wing patterns of heliconius butterflies are established. here, extensive knowledge of the ecological and evolutionary significance of wing color patterns, experimental tractability, and fantastic **\*\*diversity\*\*** make heliconius a powerful experimental system for understanding how the processes of cell specification are modified by natural selection to produce **\*\*diversity\*\***. by casting single-cell transcriptomics, open chromatin profiling and crispr loss-of-function experiments within an evolutionary framework that includes replicated cases of the independent evolution of identical wing patterns, this project will determine the rules that govern how cells communicate and acquire a specialized fate during development, and how those rules are applied to generate **\*\*diversity\*\***. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Reproductive heterogeneity in the structured coalescent framework

Awardee: Florida State University

Amount: \$410,357.00

Abstract: curbing the effects of pathogens and securing the survival of endangered or commercially exploited species is a matter of national interest. while collecting genetic data on these pathogens and endangered species has become standard over the last decade, the data requires translation and analysis to be useful for policy decisions. these data are commonly used in models that describe both the recent and ancient history of the species. these models are founded on theoretical population genetics and are often not very flexible. this research addresses the assumption that the populations that are being studied have a relatively constant number of offspring per generation. scientific observation has shown that this assumption is incorrect. for example, some sars-cov-2 strains are more successful in infecting people than others, suggesting that the ancestor with a new

mutation has many more 'offspring' than others. this research generalizes the common assumption and constructs a framework that allows for the improvement of these population models by offering an increase in accuracy and a decrease in bias. this research will result in the creation of a software tool that will benefit the research community and train the next generation researchers. accurate estimates of population size and genetic **diversity** will lead to better control of pathogen outbreaks, regulation of catch quota for commercial fishing, and maintenance of endangered species. this research explores the effect of heterogeneity of offspring production on the genealogy of a population using (1) a theoretical framework that can handle heterogeneity and the development of software to infer this heterogeneity from genomic data. this framework is based on the fractional coalescent expanded to multiple, structured populations. the research extends a single-population derivation of the fractional coalescent that incorporates offspring variability as a random variable. these new methods will be incorporated into the widely-used open-source computer software migrate. the new approach will then be compared with multi-merger coalescent methods using artificial data. these data are generated using (2) a simulator taking into account environmental quality changes within and among populations affecting the number of offspring an individual can have. (3) analyses of the effect of heterogeneity for many biological datasets over a broad range of species with different life histories: from viruses to humpback whales and from small geographic scale to large scales. these biological datasets will be analyzed in collaboration with practical scientists. software and tutorials will be reported on <http://popgen.sc.fsu.edu> and <https://peterbeerli.com>. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Characterizing Inclusive Strategies that Retain Black Students in Computer Science to Graduation and Beyond

Awardee: Clemson University

Amount: \$410,081.00

Abstract: this iuse project aims to serve the national interest by identifying factors that lead to the lack of **diversity** in computing professions. research has shown that the first two years of science, technology, engineering, and mathematics (stem) majors are often where students are lost in the pipeline. this project will identify factors that affect the retention and graduation of under-represented minority students in the computing major. the goals are to identify inclusive strategies for success in computing programs and investigate ways to increase the retention and post-graduation success of black students in computing. of particular interest are strategies that are transferable to different types of institutions and stem fields in general. this project features a collaboration between two historically black colleges/universities and a primarily white institution that will work together to understand the challenges facing each institution and the strengths each institution brings to addressing this problem. through detailed transcript analysis, this research will take an asset-based approach, focusing on the strengths of students succeeding in the major. two cohorts of lower division (freshman and sophomore) black cs students from two historically black colleges/universities (hbcus) and one primarily white institution (pwi) will be studied to measure perceived societal impacts and their understanding of content through conceptual assessment instruments. a cohort of upper division students will be studied to measure the factors that led to their success using surveys, a content assessment, and interviews. using a mixed methods analysis approach, white students will be compared to black students at the research intensive pwi and then the principal investigators will compare black students at the pwi to black students at the two hbcus. the goal is to expand knowledge of inclusive teaching strategies and provide institutional awareness of factors that can go beyond recruiting urms to focus on retention in the major and student success post-graduation. the nsf iuse: ehr program supports research and development projects to improve the effectiveness of stem education for all students. through its engaged student learning track, the program supports the creation, exploration, and implementation of promising practices and tools.

Title: Collaborative Research: US GEOTRACES GP17-OCE: Mapping nitrous oxide sources and sinks through isotopic measurements in the Pacific Ocean

Awardee: Stanford University

Amount: \$409,577.00

Abstract: nitrous oxide is a powerful greenhouse gas that is produced by microbial activity in soils and the ocean. the pacific ocean is an important component of oceanic nitrous oxide production and emission to the atmosphere due to its large area and pockets of low oxygen in the eastern tropical pacific. the largest amounts of nitrous oxide observed in the global ocean occur in these pockets of low oxygen. these regions appear to impact nitrous oxide distributions throughout the pacific ocean, but the sources of nitrous oxide in these regions may be quite different. this work will provide a better understanding of both the natural distribution of nitrous oxide in the global ocean, as well as the mechanisms and controls on its production for future emission projections. this will be accomplished by collecting nitrous oxide isotopic measurements at different water depths from the central pacific, where relatively little work has focused. measurements of nitrous oxide isotopic composition is a powerful analytical tool that will help to answer these important questions about this powerful greenhouse gas. the stanford component of this project will be carried out primarily by a phd student, who will be trained in a variety of laboratory techniques, data analysis, and computer modeling. we will also use support from this project to increase **\*\*diversity\*\*** in the geosciences by providing first-time research experiences to underrepresented minority students through stanford's surge (summer undergraduate research in geoscience and engineering) program. one of the project's lead investigators, bourbonnais, will also give a series of introductory chemical oceanography lectures at benedict college, a private historically black, liberal arts college in

columbia, sc and support two undergraduate students from benedict college through summer internships at the university of south carolina. this project will address three main questions related to n<sub>2</sub>o cycling in the pacific ocean: (1) what features of n<sub>2</sub>o distribution in the central pacific ocean are driven primarily through mixing and circulation vs. biological processes; (2) which biogeochemical processes control the distribution of biologically produced n<sub>2</sub>o in the central pacific ocean; and (3) how does the production (amount, mechanism, yield) of n<sub>2</sub>o relate to the availability of oxygen in situ? this collaborative project will be carried under the geotraces program, an international effort to understand the distribution of elements in the global ocean. with the synthesis of the geotraces gp17 and gp15 sections, we will have an opportunity to examine the distributions of n<sub>2</sub>o and its isotopes (an indicator of production mechanisms) relative to oxygen, trace elements, and water mass tracers. data from this project will be made available to the public through the biological and chemical oceanography-data management office ([www.bco-dmo.org](http://www.bco-dmo.org)). the data will also be compiled in geotraces data products that will be freely available. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: DMREF: Microstructure by Design: Integrating Grain Growth Experiments, Data Analytics, Simulation, and Theory

Awardee: University of Utah

Amount: \$409,494.00

Abstract: most technologically useful materials are polycrystalline microstructures composed of a myriad of small monocrystalline grains delimited by grain boundaries. an understanding of the evolution of grain boundaries and associated grain growth (coarsening) is essential in determining the properties of materials across multiple scales. despite tremendous progress in formulating microstructural models, however, current descriptions do not fully account for various grain growth

mechanisms, detailed grain topologies and the effects of different time scales on microstructural evolution. as a result, conventional theories have limited predictive capability. the goal of the project is to develop a predictive theory of grain growth in polycrystalline materials through the construction of novel, closely integrated data-driven numerical simulation and mathematical modeling combined with data analytics, analysis, and a set of critical experiments. this interdisciplinary project, requiring the complementary expertise of applied mathematicians and materials scientists, is firmly aligned with the materials genome initiative. the new knowledge and tools that will emerge from the project will have a profound impact on the performance and reliability of polycrystalline materials used in many technologically useful systems and structures, thereby expediting advanced materials development and deployment. predictive computational algorithms and data will be made available and accessible to other researchers. for the training of the next-generation materials workforce, in addition to mentoring of graduate and undergraduate students, the pis (from columbia university, illinois institute of technology, lehigh university and university of utah) will participate in outreach activities and will continue to work towards increasing **\*\*diversity\*\*** and broadening participation within stem.

grain growth is a very complex process and may be viewed as the anisotropic evolution of a large metastable network. one of the main thrusts of the project will be to uncover possible stochastic processes that define the evolution of various statistical measures of grain growth, discover relations among them, and establish links to materials properties. results from structure-preserving numerical simulations alongside critical sets of experiments and new experimental data will be invaluable in navigating the modeling and analysis. the project will also create and employ specific data analysis techniques for the study of dynamic evolution of grains in experimental and computational systems with the goal of validating and further refining the microstructural models. this component of the project, will lead to a) the development of new materials informatics methods, b) innovative stochastic differential equations/differential equations models of grain growth, c) new mathematical and numerical analysis techniques for coarsening systems, as well as d) improved computational tools. in turn, the results of combined data analytics,

modeling and analysis will be used to guide the design of subsequent experiments. experimentally, grain growth will be examined in prototypical metallic thin films (pd, ni, cr, fe). as most elemental metals and many metallic alloys have cubic structures, the proposed studies will have broad applicability. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: BRITE Synergy: Transforming Electron Beam Lithography with Reactive Gases

Awardee: University of Kentucky Research Foundation

Amount: \$407,998.00

Abstract: this boosting research ideas for transformative and equitable advances in engineering (brite) synergy award will support research which seeks to transform the way manufacturers perform electron-beam lithography by introducing a reactive gas that modifies the process chemistry. electron-beam lithography is critical for nearly all manufacturing at nanometer length scales and is often the first step in fabricating devices in semiconductor electronics, digital imaging, communications, and healthcare. this innovation will enable patterning of new functional materials while also improving the performance of conventional materials. the research program seeks to understand the fundamental physical and chemical mechanisms underlying the effects of reactive gases on the lithographic process, and to use this knowledge to advance lithographic performance. a broad range of industries now relies on nanoscale manufacturing, and thus on electron-beam lithography. this award could thus impact multiple sectors of the u.s. economy while accelerating product development and increasing access to nanotechnology-enabled products. this effort will also expand **\*\*diversity\*\***, equity, and inclusion in advanced manufacturing through workshops for middle-school teachers primarily serving underrepresented groups and multi-disciplinary training for graduate students recruited from underrepresented groups. electron-beam lithography is the primary pattern generation technology for nearly all nanomanufacturing, from integrated circuit mask

making to direct-writing of quantum devices. focused electron-beam induced processing in gases and liquids provides nanoscale rapid prototyping with functional materials as well as nanoscale repair and editing capabilities. this effort synthesizes research outcomes in these two areas with established knowledge in radiation chemistry and electron-material interactions to enhance understanding of the influence of reactive gases on electron-beam lithography. specifically, the research seeks to understand how reactive gases can alter radiation chemical processes to expand the range of materials that can be patterned and to improve lithographic performance for conventional electron-beam resists. a rigorous research synthesis program, hybrid monte carlo-continuum simulations, and carefully designed nanopatterning experiments will build knowledge of the relationships between process conditions, such as gas composition and pressure, and lithographic performance metrics, such as sensitivity, contrast, and resolution. success could transform electron-beam lithography because functional materials could be patterned with resolution and throughput comparable to conventional resists while the performance of conventional resists could be tuned by the reactive gas. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: MRA: Elucidating Plant and Mycorrhizal Fungal Relationships and Consequences across Space and Time

Awardee: Purdue University

Amount: \$407,353.00

Abstract: many plants are dependent on belowground fungi to help them obtain nutrients and respond to environmental stress. revealing the patterns and drivers of these interactions is important for understanding forest ecology and improving management practices. plant-fungal associations in the soil can dramatically influence plant growth and terrestrial ecosystem function. this research will take the advantage of several existing datasets, including those collected by national ecological observatory network (neon) and the u.s. forest service (usfs), to understand: 1) nation-wide patterns of plant-fungal associations; 2) key factors that influence these associations; and 3) how plant-fungal interactions influence key ecosystem functions such as carbon cycling. this research project will contribute to the fields of microbial ecology, ecosystem science, and global change biology by formulating and testing new theories about plant-fungal associations. results of the project will inform forest managers, policymakers, and other stakeholders on how to improve ecosystem management of plant and fungal bio\*\*diversity\*\* to promote sustainable ecosystems. the project will contribute to the professional development of diverse students at several stages. the goal of this project is to understand the patterns, drivers, and consequences of the linkages between plant and mycorrhizal fungal \*\*diversity\*\* across spatial and temporal scales. this information will enable better predictive understanding of essential ecosystem functions which they control. the project will use a holistic, scale-dependent framework that forecasts the strength and direction of arbuscular mycorrhizal (am) and ectomycorrhizal (em) fungal-plant associations, and provides greater insight about the consequences for ecosystem functioning across space and over time.

specific objectives of the project include: 1) elucidation of patterns of plant and mycorrhizal fungal **diversity** across scales by extensive dna sequencing and analysis; 2) determination of key abiotic and biotic drivers of observed co-occurrence patterns; and (3) forecasting the effects of plant-mycorrhizal fungal couplings on tree productivity and soil c storage, two key forest ecosystem functions. by linking multiple facets of both above- and belowground **diversity** in a scale-dependent context, the project will produce robust continental-wide distribution maps of am and em fungi for the first time. leveraging data-rich sampling of putative biotic and abiotic drivers of plant and fungal **diversity** by neon and the usfs, the project will also provide broad-scale understanding of when and where these drivers serve to couple or decouple plant and mycorrhizal fungal **diversity**. finally, by linking plant and mycorrhizal fungal **diversity** to the consequences they have for plant productivity and soil c storage and stability, the project will improve understanding of ecosystem resilience to environmental stress. the project will train diverse undergraduate and graduate students, postdoctoral scholars, and will enhance the development of three early-career scientists. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Probing Cellular Dynamic Mechanobiology Using Human Cardiomyocytes on a Stimuli-Responsive Nano-Topographic Substrate

Awardee: Syracuse University

Amount: \$406,551.00

Abstract: this grant will support a multidisciplinary research that will enable new approaches in dynamic cell mechanobiology and smart biomaterials. traditionally, cell mechanobiology is studied using static culture systems. though useful, these systems provide little knowledge as to how the cells respond to a dynamic changing microenvironment, such as in the body. this project aims to

develop in vitro models and approaches that include time-dependent mechano-structural cues to cells. these physical cues are important to regulating of cellular morphology (shape), differentiation (what cells become), and function at each phase of tissue development or healing. the knowledge gained through this project will have a broad impact and various applications in the scientific fields related to developmental cell biology and cardiac pathophysiology. this project is also designed to integrate research, education, and **\*\*diversity\*\*** with an emphasis on strengthening research exposure and opportunities at different education levels. the educational component of this project aims to help raise the awareness and familiarity of high-school students and undergraduate students with interdisciplinary, emerging and socially compelling directions within biomedical engineering. the goal of the present research is to use an in vitro shape-memory polymer (smp) platform to investigate how dynamic topographic structural cues affect cellular mechanobiology, with a particular emphasis on the focal adhesion dynamics of human cardiomyocytes. the combination of dynamic biomaterial substrates, hipsc technology and genome editing will provide a great potential to establish new analytical tools and in vitro model systems for broadly studying time-dependent mechano-structural cues in dynamic cell mechanobiology. this dynamic platform will allow us to test our hypothesis that extracellular topographic changes will dictate the different dynamic responses of both periphery focal adhesions and sarcomere-linked costameres of cardiomyocytes, thereby reorganizing myofibril structures and controlling contractile functions. this project aims to study how dynamic structural cues would regulate periphery focal adhesions (objective 1) and cardiac-specific sarcomere-linked costameres (objective 2), and how mechanotransduction signaling pathways (fak and yap/taz) are involved in these cellular developmental processes (objective 3). this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: FSML: SERC Visiting Scientist Cottages

Awardee: Smithsonian Institution

Amount: \$405,804.00

Abstract: the smithsonian environmental research center (serc) provides field, lab and convening facilities at its 1,000 ha property on the shores of chesapeake bay in support of research on the interactions among ecosystems of the coastal landscape in response to climate and human impacts. with this award, serc will build on-site short-term housing for visiting scientists relieving presently inadequate and deteriorating housing facilities that lack ada accommodations. this investment is part of a much broader master plan for growing accommodation at serc; it will ensure continued access for critical on-going research and will enable expanded opportunities for outreach. serc is unique in its combined estuarine and terrestrial research that provides important long-term and large-scale data and unique experiments on land-sea interactions and responses to environmental change. it hosts numerous major research projects including participation in the national ecological observatory network; long-term research on the effects of elevated co2, stream discharge and water quality, estuarine fish & invertebrate community dynamics, tree demography; and experimental research on tree species **diversity** and ecosystem function. access to these resources provide rich and diverse opportunities for visiting scientists to conduct both new research within the context of extensive background data and synthesis of multifactorial interactions. access to serc resources also provide unique opportunities for undergraduate intern training and graduate dissertations. approximately 60 active extramural research projects leverage an array of long-term datasets, and the datasets are highly valued by our academic and governmental sponsors and collaborators. serc facilities support a 50-year history of both providing access to visiting scientists and informing environmental policy makers on emerging environmental issues. short-term housing enables visiting researchers and educators to use serc's unique resources and site most efficiently and cost-effectively. serc's site is also hosts numerous tours for congressional staff members and politicians from nearby washington, dc, and the maryland capital annapolis. u.s. state department often features serc in tours of international visitors working on environmental resource management.

serc facilities are also an important resource for serc's diverse array of collaborative research and training programs for academic partners. the facility is a central feature of serc's professional training that annually supports 55 interns, 10 grad students, 25 postdocs and 570 visiting scientists for short and long periods. approximately 130 of these visiting scientists actively conduct research on the site for multiple days at a time, and over 400 attend meetings, workshops and training annually. for more information on serc, see <https://serc.si.edu/>. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Contribution of mafic magmatism to upper crustal batholiths: A case study of the Sierra Nevada batholith

Awardee: California Institute of Technology

Amount: \$405,087.00

Abstract: the dense crust beneath earth's oceans is regularly driven beneath the continents in a

tectonic process called subduction, which results in the formation of magmas. such magmas ascend and create long chains of volcanoes like the cascades of the northwest united states or the andes in south america. over time, magmatism at subduction zones has helped build earth's continents. these magmatic processes concentrate silica to create thick and buoyant continents that stand higher than surrounding oceans and oceanic crust, which is a unique feature of our planet. this continental crust is an important source for resources essential to human existence, but the processes that concentrate silica in magmas are not fully understood. this research will study magmatic processes in the sierra nevada mountain range of california, which is the ancient 'plumbing system' from the insides of subduction zone volcanoes from hundreds of millions of years ago, now exposed at earth's surface. this work will study the chemistry of mafic (more magnesium and iron-rich, lower silica) rocks that represent an important compositional ingredient to create the high-silica rocks that form the bulk of the continents. extensive existing work on the high-silica rocks at this location will provide context for new measurements of the mafic end-member composition to understand the magmatic processes that build continents. the research will support collaboration between caltech and pomona college, including the mentoring of a female graduate student (caltech) and multiple undergraduate/post-baccalaureate students (pomona), as well as early career support for a female faculty member (caltech). in addition, earth science classroom lessons and field trips for middle and high school students from the big pine unified school district (bpusd) in owens valley, located within study area will be developed and conducted. bpusd serves a student population that is ~50% native american and >40% latinx, two under-represented groups in geosciences. the ultimate goal is to increase participation and interest of under-represented students in geosciences through place-based and culturally appropriate lessons that successfully aligned indigenous ways of knowing and scientific practices with western science models the formation of high-silica arc batholiths is an enduring petrologic problem. during flux-melting of the mantle wedge at subduction zones primitive basalts are produced. upon ascent into the crust, further differentiation of these basalts is required to form more silicic derivative melts. although field

and experimental studies highlight the importance of lower crustal ( $>0.7$  gpa) fractional crystallization of primitive basalts in generating high-silica melts, this process in detail cannot produce the composition of arc batholiths. In particular, deep crustal fractional crystallization generates peraluminous intermediate and silicic melts, compositions that are not widely observed in arc batholiths. To reconcile these observations, this research will test the following hypothesis: deep crustal differentiation produces high-al, low-mg basalts, as well as, evolved mildly peraluminous granitic melts. These melts represent endmembers that can mix to form the compositional **\*\*diversity\*\*** of granitoids observed in arc batholith. Testing this mixing-model hypothesis has been limited due to the relative lack of studies focusing on the mafic endmember. Although volumetrically minor and relatively less-studied compared to high-silica granodiorites to granites that dominate batholiths, mafic plutons (non-primitive gabbros and diorites) are widely present in the upper crust of accreted arc sections. Through a collaboration between Caltech and Pomona College this research will investigate the bulk-rock and mineral major/trace element chemistry, geochronology, and oxygen & strontium isotopic compositions mafic plutonic bodies across a transect from a classic continental arc locality, the Sierra Nevada batholith. This data will be placed in the context of both existing and new granitoid data, as well as, quantitative geochemical and rheologic models to understand whether these mafic plutonic bodies represent suitable mixing endmembers in the production of batholithic granitoids. This award reflects NSF's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: REU Site: Imaging in Medicine and Biology for Underrepresented Minorities

Awardee: University of Rochester

Amount: \$405,000.00

Abstract: diverse teams are needed to solve complex engineering problems. however, the lack of research opportunities in engineering and other stem-related fields prevents undergraduates from underrepresented groups from considering stem as a viable and rewarding career path. to improve this situation, this imaging in medicine and biology for underrepresented minorities reu site will provide an environment for underrepresented minorities (urm) undergraduates to complete individual research projects under the mentorship of leaders in their respective fields, in a world-class interdisciplinary research environment. the imaging in medicine and biology for underrepresented minorities reu site will also provide structured enrichment programs to participants that will allow students to develop critical skills needed to be successful in stem graduate education (gre preparation, time management, oral/written presentation). the university of rochester (ur) is an ideal setting for this reu site; it is the home of the rochester center for biomedical ultrasound (rcbu), the institute of optics, the goergen institute for data science (gids), and the del monte institute of neuroscience?members of which will serve as mentors in this reu site. imaging is crucial to medicine (disease diagnosis, treatment planning, and monitoring), but it is also the driving force behind many transformative technologies, including robotics, self-driving cars, and facial recognition. at its foundation, imaging is a highly multidisciplinary field that combines various engineering disciplines (e.g., electrical engineering, computer science, physics, chemistry, materials science, and medicine) to create a cohesive whole. like other disciplines, artificial intelligence is changing imaging. it requires diverse teams to solve new challenges, which requires us to train and expand the **\*\*diversity\*\*** of researchers capable of making meaningful contributions to imaging science and engineering. this reu program will provide ten students annually with exciting interdisciplinary research opportunities in computational imaging, optical imaging, and ultrasonic imaging science with mentors in disciplines ranging from engineering to computer science to neuroscience to microbiology. the reu site program will organize workshops on career development, community colloquiums, scientific research in chosen laboratories, and a bootcamp on scientific programming focusing on fundamental medical imaging techniques. students will regularly meet with professional

and research mentors to formulate the next steps regarding appropriate graduate programs that align with research interests discovered during the reu experience. participants in the reu site will complete individual projects under the mentorship of leaders in their respective fields. in these projects, participants will use computational, optical, or ultrasound imaging techniques to solve significant medicine and biology problems. participants will interact with their professional advisors to demystify the graduate school program and improve their professional skills. other planned activities will include community colloquiums, a matlab programming bootcamp that teaches students image processing techniques such as image segmentation, principal component analysis, and multidimensional filter design, which are fundamental to medical imaging. students will work with their professional and research mentors to formulate the next steps to pursue their research interests. research mentors in the proposed reu will teach participants how to develop their research project; collect data from several imaging modalities (functional ultrasound, shear wave elastography, bioluminescence, micro-ct, magnetic resonance imaging); design algorithms for image analysis, 2d and 3d image reconstructions, computer vision; perform experiments on rodents, cell culture, and phantoms; and iteratively refine the solutions. students will present their research findings to other students, mentors, and the research community at ur at a research symposium at the end of the 10-week research experience. students will also be encouraged to submit their research findings to national conferences or co-author peer-reviewed publications. three thematic research areas will serve as the foundation for this reu site: 1) ultrasonic imaging, 2) computational imaging, and 3) optical imaging. this site is supported by the department of defense in partnership with the nsf reu program. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: REU Site: Green Infrastructure for Sustainable Urban Environments (GI4SUrE)

Awardee: University of Tennessee Knoxville

Amount: \$404,784.00

Abstract: in this research experiences for undergraduates (reu) site program, green infrastructure for sustainable urban environments (gi4sure), a diverse cohort will participate in research supporting the advancement of green infrastructure to improve public and ecological health in urban environments. green infrastructure can be described as the interconnected natural spaces in urban environments such as parks, riparian areas, and nature-based storm water control measures that serve to clean storm water runoff, reduce urbanization impacts to local surface waters, and offer protection from flooding. research will include state of the art field, laboratory, and modeling studies to better understand and optimize these systems. students that participate in this reu will have the chance to improve their research and critical thinking skills while bolstering their ability to communicate with technical and non-technical audiences through oral and written mediums. additional experiences include access to new mentors, exposure to the various career pathways made possible by a graduate degree in engineering, and training on how to collaborate with, learn from, communicate with, and consider the perspectives of colleagues outside their discipline. this program will serve to improve the **\*\*diversity\*\*** of the engineering profession and student participation in graduate school by extending opportunities to traditionally underrepresented groups in science and engineering. through a 10-week, summer undergraduate research experience, the gi4sure reu site aims to: (1) propel scientific knowledge regarding green infrastructure (gi) contributions to sustainable urban water, and (2) provide a high quality professional and social atmosphere where attendees are educated on fundamental research methodologies and critical thinking. under the guidance of faculty mentors, students will perform field, laboratory, and/or modeling studies to explore how gi functions to mitigate the effects of urban runoff on surface water quality and hydrology. green infrastructure has been deemed as a way to build better infrastructure

as part of the national academy of engineering's grand challenge to restore and improve urban infrastructure, making it a vital topic for investigation. reu students will be exposed to state of the art techniques and convergent research by the inclusion of non-engineering co-mentors in a subset of the projects to address complex questions that consider social, hydrologic, ecologic, and/or economic outcomes. through a targeted recruiting strategy, this reu site will bolster the participation of traditionally underrepresented groups in undergraduate engineering research. students will gain skills in research methodology, communication, convergent approaches, and working in team environments which will be invaluable in their professional endeavors. further, exposure to the various career pathways that are open to individuals with advanced degrees will aid them in determining their desired career path, whether it be academia, industry, government, or non-government organizations. reu contributions to gi knowledge will be invaluable. as billions of dollars are being spent nationwide to reduce the effects of urbanization through the use of gi, there is a critical need to better understand and optimize its performance to make these efforts more scientifically informed. overall, the reu intends to establish direct, lasting mentoring relationships between participants and faculty, and long-term relationships among those in the cohort. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Quantum optics with nonlinear organic small molecule enhanced integrated photonics devices

Awardee: University of Southern California

Amount: \$404,374.00

Abstract: quantum networking has emerged as a global grand challenge in the field of quantum information sciences, identified as a critical technology for enabling general purpose quantum computing and its applications. therefore, developing implementable devices to accelerate quantum networking will advance us security and technical leadership. a flexible quantum network will have the ability to transmit an arbitrary quantum state with high-fidelity over room- (data-center), metropolitan- (lan), continental- and trans-continental-distances. in this proposal, we provide a path for the development of quantum frequency converters (qfc?s) for translating the wavelength of photons into and between pre-assigned channels of the international telecommunication union (itu) frequency grid, while preserving the delicate quantum information that is encoded on those photons. the planned approach is fully compatible with silicon photonics technology providing a scalable, robust, manufacturable platform for the generation of non-classical light and frequency translation of that light. the training and outreach efforts directly engage the scientific community and the general

public. in collaboration with usc's center for engineering **\*\*diversity\*\***, two undergraduate student researchers will be hosted in the pi and co-pi's laboratories, and a free online quantum optics conference will be organized. the past decades have witnessed a rapid increase in the performance of on-chip integrated photonic devices for studying nonlinear and quantum phenomena. these devices have enabled a wide range of discoveries and are serving as critical roles in our optical communications network. however, as we look to shift from classical to quantum networking, we must be mindful to engineer components that enable quantum communications and yet are compatible with the large existing infrastructure already in place for classical optical communications. an important capability in quantum networking is making quantum information, stored on optical qubits, compatible with the modern telecommunications infrastructure, which includes mapping quantum channels to the international telecommunication union (itu) frequency grid. one approach being explored relies on frequency conversion using integrated optical resonant cavities. while the concept is theoretically robust, in practice, there are several hurdles related to low conversion efficiencies and optical power requirements that must be solved. while it is possible to overcome the power requirements by using a cavity with a long photon lifetime, the conversion efficiency is intrinsic to the cavity material. in the present work, we will explore a new type of hybrid optical cavity comprised of a self-assembled monolayer of nonlinear optical organic materials on a silicon oxynitride microring. organic materials possess 1,000-100,000x higher non-linear optic (nlo) coefficients than conventional optical materials; thus, the proposed hybrid system could provide a transformative solution to the current challenge. the key quantum capability of the microresonators to be validated is coherent wavelength translation of an optical state while preserving the quantum coherence of observables on which quantum information is encoded. the si device architecture that will be studied is compatible with existing infrastructure; thus, this work will pave the way for establishing the quantum network using the existing itu grid. undergraduate and graduate students will be directly engaged in all aspects of the research, and all findings will be disseminated using scholarly publications as well as social media. this award reflects nsf's statutory mission and has

been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Awardee: University of Texas at San Antonio

Amount: \$403,859.00

Abstract: this award is funded in whole or in part under the american rescue plan act of 2021 (public law 117-2). despite concerted effort over the last two decades, the size and **\*\*diversity\*\*** of the geoscience workforce has not significantly changed to meet the projected demand for geoscientists, which has major consequences for the sustainability of natural resources and overall environmental quality that supports a strong economy and ensures the health and welfare of all united states residents. this project aims to address this shortfall using an innovative curriculum program to recruit and retain more undergraduate students from historically excluded groups; it will promote interest in geoscience within 2-year institutions where geoscience courses are limited and facilitate transfer pathways from 2- to 4-year institutions and retention to degree completion so students earn the educational credential needed to enter the geoscience workforce. the new insights gained from the program will form a model of best practices that can be adapted and implemented at other universities to grow a larger, more diverse geoscience workforce. this project aims to broaden participation and enhance retention in geoscience by implementing and testing the effectiveness of a three-stage early intervention strategy within the undergraduate degree arena. conducted at the hispanic serving institutions of northwest vista college and the university of texas at san antonio, the three-year program will generate greater awareness of and interest in geoscience in introductory stem courses and promote retention through extracurricular service-learning projects. in introductory geoscience, chemistry, and physics courses, four modules will test the effectiveness of a recruitment

strategy that targets specific barriers and motivations to broaden and diversify the pool of geoscience majors and minors. participants will be supported by multi-level mentoring, advising, a transfer bridging event, and stipends; a program-specific interactive website will facilitate formal and informal learning and interactions between students, faculty, professionals, and community. the project design permits a critical test of a recruitment approach that targets a wider pool of potential majors and the critical elements of service-learning projects that promote learning and retention. the new knowledge identified from formative and summative program assessments will be widely transferrable because it focuses on introductory courses that are generally offered at many institutions and experiential learning experiences that can flourish independently from formal coursework. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: RCN: Ecological and Evolutionary Effects of Extinction and Ecosystem Engineers (E6)

Awardee: University of Nebraska-Lincoln

Amount: \$400,219.00

Abstract: ecosystem engineers are organisms that change the environment in which they live, and can create or eliminate habitats for other taxa. ecosystem engineers therefore can be important drivers of local and regional **\*\*diversity\*\***. our own species ? humans ? offer a powerful example. humans have adopted behaviors that have created, modified, and/or destroyed habitats used by a wide variety of animals and plants. the effects of these activities are leading to dramatic changes in the structure and function of ecosystems, and the current global bio**\*\*diversity\*\*** crisis that has been termed the ?6th mass extinction?. thus, some consequences of human activities are comparable to the environmental perturbations associated with mass extinctions, whereas others may be creating new ecological opportunities. a key question is therefore: what effect will human ecosystem engineering behaviors have as we continue to modify the global environment? this research

coordination network will bring together ecologists and paleontologists to synthesize information on the effects of ecosystem engineers in different kinds of biological systems at different times to develop predictive models for how human activity is expected to affect ecosystems. the researchers will also conduct outreach activities designed to increase **diversity** in stem fields using partnerships with local community colleges, an undergraduate course taught concurrently at member institutions, and a conference workshop. the key to predicting the effects our activities may lie in the past. although humans are among the most recently emerged ecosystem engineers with powerful effects, they are not the first. the evolution of biological groups such as oxygenic photosynthesizing cyanobacteria, marine animals capable of burrowing beneath the sediment surface, a wide variety of reef-building organisms and land plants are all thought to have had dramatic effects on global bio**diversity**. this research coordination network will synthesize existing data across nearly 600 million years of evolutionary history to address the questions: 1) to what extent are the effects of new ecosystem engineers on communities predictable? and, 2) to what extent do we expect humans to continue to drive the 6th mass extinction, and/or create new ecological and evolutionary opportunities? the e6 rcn will unite scientists from the fields of paleobiology, geology, ecology, statistics, conservation, and phylogenetics to contrast the ecological and evolutionary consequences of ecosystem engineers. activities will include twice yearly workshops and training of graduate students, postdocs, and faculty. in partnership with the university of california museum of paleontology, researchers will develop and run a paleobotany and paleoclimatology lab for bay area community college students. an interdisciplinary course on extinction and ecosystem engineers will be taught concurrently at participant institutions, and a workshop on approaches for studying ecosystem engineers and community ecology at large spatial and temporal scales will be developed for national and international conferences. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: FET: Medium: Neuroplane: Scalable Deep Learning through Gate-tunable MoS2 Crossbars

Awardee: University of Illinois at Chicago

Amount: \$400,000.00

Abstract: the increasing complexity of deep-learning systems has pushed conventional computing technologies to their limits. while the memristor is one of the prevailing technologies for deep-learning acceleration, it is only suited for classical learning layers where two operands, namely weights and inputs, are processed at a time. meanwhile, to improve the computational efficiency of deep learning for emerging applications, a variety of non-traditional layers, requiring concurrent higher-order processing of many operands, are becoming popular. for example, hypernetworks improve their predictive robustness by simultaneously processing weights and inputs against the application context. two-electrode memristor grids cannot natively support such operations of emerging layers. addressing the unmet need, this research will develop neuroplane -- a novel deep-learning accelerator of gated memtransistor crossbars. exploiting crossbars' gate controllability, multiple operands can be processed within the same crossbar unit in neuroplane. many advanced inference architectures that can generalize beyond a typical passive crossbar will thus be possible. overall, the ultra-low-power, higher-order processing of neuroplane will harness high robustness and efficiency of emerging deep-learning layers within area/power-constrained devices such as mobile, sensor, and embedded systems. the investigators will develop fabrication methods for nanometer node gate-tunable dual-gated crossbars of mos2 memtransistors. a self-aligned fabrication method with defect passivation and process variability compensation will be created. exploiting the gate-tunability of mos2 memtransistors, a new generation of crossbar platforms with many runtime control knobs will be developed, rendering the design a high elasticity and agile computing space. for example, computing methods will be created for the gated crossbars to utilize crossbar elements for product-sum digitization, thereby preventing the critical overheads in

current crossbar technologies. similarly, control-flow methods will be developed for gated crossbars to adapt their inference paths depending on the input characteristics by dynamically deactivating input/output neurons to conserve processing energy. a coherent collection of software and hardware-based correction techniques is proposed to minimize the impact of process variability. unlike the current schemes, by following the train-once-deploy-anywhere tenet, the proposed crossbar correction methods can scale to millions of deployments without considerable overhead. an annual workshop will be conducted at local high schools with substantial ethnic and gender **\*\*diversity\*\*** to mentor underrepresented students. undergraduate research projects will be sponsored using paid summer internships and university-level programs such as summer undergraduate fellowship. an inter-university senior-design mentoring program will be created for students among participating institutions. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Measuring and Reducing Algorithmic Discrimination with Quasi-Experimental Data

Awardee: Harvard University

Amount: \$400,000.00

Abstract: this research project will develop new tools to measure and reduce algorithmic discrimination in several high-stakes settings. algorithms guide an increasingly large number of decisions. alongside this rise is a concern that algorithmic decision-making will entrench or worsen discrimination against legally protected groups. however, quantifying algorithmic discrimination is often hampered by a selection challenge: an individual's qualification for a decision, which is often used to define discrimination, is typically only available for the group of individuals who were selected for treatment by an existing human or algorithmic decision-maker. this project will overcome this fundamental selection challenge by developing new tools to measure algorithmic discrimination. the project also will develop alternative algorithms that minimize or reduce discrimination. the researchers will apply these tools in multiple high-stakes settings, including pretrial detention, employment screening, medical testing, and child welfare investigations. the research is of considerable policy interest given the rapid adoption of algorithms in a variety of settings. the investigators are committed to increasing **\*\*diversity\*\*** in the economics research community by recruiting, training, and mentoring women, under-represented minorities, and first-generation college students as undergraduate research assistants and predoctoral fellows. code produced by this project will be made publicly available. this research project will develop tools to measure algorithmic discrimination. the project also will develop alternative non-discriminatory algorithms when qualification is unobserved for a subset of individuals. for example, in the employment context, whether an individual would be hired after an interview is not observed for applicants screened out before the interview is held. the investigators will show that

this selection challenge can be overcome with knowledge of average qualification rates across different groups. further, these average qualification rates can be estimated by utilizing random assignment of decision-makers to individuals. this insight can be used not only to measure algorithmic discrimination, but to develop alternative algorithms that reduce or eliminate discrimination. the project will consider several extensions. the investigators will utilize experimentation to measure algorithmic discrimination and improve accuracy. the interaction between algorithms and human decision-making also will be explored, as human discretion remains important in most real-world settings. the results of this research will have implications for more accurately quantifying the trade-offs between algorithmic transparency, accuracy, and fairness. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Chemical Bonding in Redox-Active Oxyfluorides

Awardee: University of Illinois at Chicago

Amount: \$400,000.00

**Abstract:** non-technical summary redox intercalation reactions are reactions during which electrons (negative charges) are transferred from one chemical building to a different one. in solid materials these reactions are essential to create battery technologies currently on the cusp of transforming human mobility. ideally new electrode materials allow large changes of charge, which maximizes energy storage, but these changes must also be reversible for extensive cycling and long battery lifetimes. this project, supported by the solid state and materials chemistry program in the division of materials research at nsf, seeks to build comprehensive descriptions of the chemical bond in oxyfluoride materials that are emerging as alternatives to pure oxides in cathodes for li-ion batteries with high energy density. the researchers investigate the role of fluoride ions to manipulate the underlying redox reaction, with especial attention to its participation in charge compensation. the research not only assesses the viability and design rules of oxyfluoride materials as practical battery electrodes, but also amplifies existing general theories of bonding in inorganic crystalline solids. the research has the potential to inform the discovery and design of mixed-anion materials with groundbreaking properties, even beyond battery applications. the research topic provides the driver for an educational plan with the unified goal to guide students toward energy applications, an area of the job market where growth and demand are still just onsetting. professor cabana's portfolio of education and outreach activities spans from elementary to graduate school, from local institutions to national events, with an emphasis in **\*\*diversity\*\*** by targeting members of hispanic communities.

**technical summary** the capacity of transition metal oxides as battery cathodes is maximized when high oxidation states can be achieved, but these states are not stable, leading to irreversibility and failure. oxyfluorides have recently been explored as alternatives, but the resulting synergies between anions remain to be ascertained, particularly the role of the halide when metals reach high formal oxidation states. this project, funded by the solid state and materials chemistry program in the division of materials research at nsf, leverages and expands methodologies of x-ray spectroscopy to uncover the balance of burden of metals and anions in redox compensation of oxyfluorides. the research spans to phases with late metals because their high formal oxidation states are known to

place the most stringent chemical demand on the anions, while also providing relevance to modern trends in batteries. this research aims to define fresh avenues to tailor materials to effectively and reversibly store large amounts of electrochemical energy, building new knowledge of the chemical bond that has the potential to transcend current boundaries of both chemistry and battery research. a tightly integrated educational component promotes materials chemistry and energy topics among the next generations. it includes outreach to local elementary schools and a national summer workshop on the frontiers of research in electrochemistry. the researchers also recruit undergraduates to conduct projects in support of this research, including through partnerships with hispanic organizations at the university of illinois at chicago. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Transforming Ethical STEM by Engaging Indigenous Research Methods in Native Environmental Science

Awardee: Northwest Indian College

Amount: \$399,935.00

Abstract: this project examines and documents the impacts of engaging with indigenous research methods and pedagogy in the science, technology, engineering and math (stem) fields. the native environmental science program (nes) at northwest indian college (nwic), situated within lummi nation's traditional territory with six extended campuses throughout the pacific northwest, is in a unique position to give voice to ethical research in stem. while there is some documentation about the impacts of engaging in indigenous research methodology in the social sciences, less is known about the impacts of engaging with indigenous research methods in stem. nwic's nes program is well positioned to influence the culture of stem education, more broadly, because of its commitment to engaging in methodologies and topics that align with community values and are identified as

community priorities. the **\*\*diversity\*\*** of students, themselves, with more than 130 different indigenous nations represented at nwc, provides a unique (and under-reported) lens to view science education and the growth of the stem field. this project addresses the need to develop culturally responsive and ethical research methodologies and practices for conducting relevant and transformational research in indigenous communities. this project documents the impacts of investing in tribal college science programs and developing culturally responsive and ethical research methodologies. specifically, this project investigates the question, "how does engaging with indigenous research methodology and pedagogy impact the educational pathways of indigenous students in the stem field?". answering this question will help contribute to a greater understanding of ethical research practices in the stem field, highlight best practices to support indigenous scientists, and lead to greater **\*\*diversity\*\*** and representation in the stem field. this investment in tribal college science programming is an investment in increasing the **\*\*diversity\*\*** in the stem fields, in general, while shaping innovative approaches to solving complex problems. engaging in ethics research involving indigenous science will provide a significant opportunity to grow and strengthen indigenous scientists while informing both minority-serving and predominately white academic institutions and stem practitioners. this project will provide a longitudinal study of indigenous students engaging in stem education over twelve years and an institutional autoethnography documenting program development. the project will also conduct focus group conversations with science faculty and advisors for high schools connected to northwest indian college and other tribal college science programs. the project addresses the need to develop culturally responsive and ethical research methodologies and practices for conducting relevant and transformational research in indigenous communities, and the research will be the first to comprehensively analyze the impacts of investing in tribal college science programs. this project will help answer the question, "how does engaging with indigenous research methodology and pedagogy impact the educational pathways of indigenous students in the stem field?" with two goals: 1) contribute to a greater understanding of ethical research practices in the stem field through

engagement with indigenous research methods and pedagogy and highlight best practices to support indigenous scientists and 2) greater **\*\*diversity\*\*** and representation in the stem field. analyzing the transformations of native environmental science research and practice in a tribal college setting will yield much-needed insights into how other research programs may adjust their research practices to promote inclusivity in research methods and design. following indigenous research methodologies prioritize community-identified research projects, reciprocity to and consistent engagement with community, and inclusivity of multiple ways of knowing. in addition, this process values indigenous knowledge holders as experts in the field and meaningful contributors to research and pedagogy. through this process, we will contribute to a wider understanding of the applications of indigenous research methodologies in stem disciplines. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: SaTC: EDU: Secure and Private Artificial Intelligence

Awardee: Georgia State University Research Foundation, Inc.

Amount: \$399,681.00

Abstract: as artificial intelligence (ai) is incorporated into more systems, there are growing cybersecurity concerns related to privacy protection as well as a need for highly trained professionals who can develop and deploy trustworthy ai systems. the goal of this project is to develop instructional materials that expose students to privacy issues inherent in ai systems through real-world examples. the project will have a direct and long-term impact by addressing the growing national need for highly trained professionals capable of taking a holistic approach to solving real world problems in complex ai systems. in addition, the project will benefit numerous students from underrepresented minority groups and improve **\*\*diversity\*\*** of the workforce. georgia state university is a minority-serving institution and has strong connections with historically black colleges

and universities (hbcus) in metro atlanta and the wider region. the project will disseminate the developed materials through training workshops for the educational community and therefore promote adoption of training modules addressing privacy and ai. the interdisciplinary project team will develop a new course, "private ai", which will include instructional modules and hands-on labs that employ state-of-the-art private ai techniques addressing different privacy challenges of ai systems. these instructional modules will be designed according to learning science principles, specifically the principles of problem-centered instruction (pci). the modules will be based on real-world systems and are designed to cover fundamental privacy principles in ai systems and practical skills systematically. the learning objectives of the interactive curricular activities are for students to (i) understand fundamental concepts and principles of private ai; (ii) understand privacy attacks and defenses, different privacy-preserving techniques, and the pros and cons of each approach; and (iii) gain knowledge and skills in the development and deployment of private ai systems. the deliverables also include manuals to help instructors integrate the modules into their curricula and guidelines on implementing pci activities in the classroom since many instructors are not experts in instructional sciences. in order to simplify integration and encourage adoption, the modules and the labs will be based on open-source software and tools that are free to use for educational purposes. the modules will also be distributed via free cloud platforms. this project is supported by the secure and trustworthy cyberspace (satc) program, which funds proposals that address cybersecurity and privacy, and in this case specifically cybersecurity education. the satc program aligns with the federal cybersecurity research and development strategic plan and the national privacy research strategy to protect and preserve the growing social and economic benefits of cyber systems while ensuring security and privacy. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Was There a Shift Toward Small, Non-Fossilizing Plankton after the End of the Cretaceous Mass Extinction?

Awardee: University of Texas at Austin

Amount: \$398,892.00

Abstract: phytoplankton, which live in the surface ocean, produce organic matter from sunlight and carbon dioxide. this primary production forms the base of most marine food webs and is a critical part of the global carbon cycle. in the modern ocean plankton are being impacted by warming and ocean acidification. natural changes in ocean temperature and chemistry in the geologic past can help us understand the long-term effects of stressors such as warming and acidification. the cretaceous-paleogene (k-pg) mass extinction event ~66 million years ago was one such time of global change. calcareous (fossil-forming) nanoplankton were one of the dominant primary producers in the cretaceous ocean. however, 93% of species of this group went extinct at the k-pg boundary, and they were never again as dominant. previous studies of the plankton response to the k-pg event have generally been limited to studies of species which leave a physical fossil record. thus, these studies provided only a partial view of ancient plankton ecosystems. the proposed work will overcome this limitation by using chemical fossils called biomarkers. these new data will be used together with traditional physical fossils to reconstruct changes in the marine plankton community following the k-pg event. it has often been assumed that non-fossilizing phytoplankton filled the gap left by the decline in calcareous nannoplankton. this study will help test that hypothesis. documenting the changes in both non-fossilizing and fossilizing plankton will improve our understanding of long-term changes in plankton ecology, and of how those changes could alter the ocean carbon cycle. this project will train early career researchers and undergraduate students, and will disseminate results to broader audiences through outreach and educational activities in partnership with organizations and programs in austin, tx and boulder, co. the project will develop datasets of lipid biomarkers, calcareous nannoplankton, and planktic foraminifera from 5 sites in tunisia, spain, and the us gulf coast. three sites in tunisia (el kef, elles, and el melah) represent a

depth transect on a continental shelf (paleodepths of 200-500 m), caravaca represents deeper water (~600-1000 m), while brazos represent a shallow shelf which will allow us to test regional variability between north africa and the us gulf coastal plain. these data will allow tests of the following hypotheses: 1. a low-**diversity** assemblage of non-fossilizing phytoplankton bloomed in the aftermath of the k-pg extinction, during the time of low **diversity** calcareous nannoplankton ?disaster? assemblages. 2. subsequent recovery of calcareous nannoplankton **diversity** is associated with a decline in non-fossilizing phytoplankton. 3. shifts in the heterotrophic planktic foraminifera assemblages are tied to turnover in the whole autotrophic plankton assemblage. 4. the post-extinction community of primary producers was dominated by smaller phytoplankton like algae and cyanobacteria, and would have increased carbon recycling in shallow waters and reduced carbon export to the deep sea. the study will improve our understanding of the recovery after the end cretaceous mass extinction and in our overall understanding of the role of plankton ecology in marine ecosystem change. additionally, reconstructing the whole plankton ecosystem, and not just the part that fossilizes, would represent a significant improvement of our toolkit to investigate ancient oceans. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: CAREER: Multi-atomic Layered Electronic Metal-organic Materials

Awardee: University of Wisconsin-Madison

Amount: \$398,848.00

Abstract: non-technical summary metal-organic hybrid materials (moms), such as coordination complexes, coordination polymers (cp), and metal-organic frameworks (mofs), possess vast structural **diversity** and thus have been extensively investigated for magnetism, catalysis, sensing, gas storage and separation, and biomedical applications. ideally, embedding the synthetic tunability of moms with the electronic properties (e.g., electrically conductive moms, called emoms)

would expand the molecular functionality of conventional inorganic electronic materials, offering new opportunities to address challenges in many vital electronic/electrochemical devices, including wearable devices, sensors, electrocatalysts, and electrochemical energy storage. unfortunately, to-date conventional mofs are primarily insulators by nature. with this career project, supported by the solid state and materials chemistry program in the division of materials research, prof. dawei feng studies a general approach to synthesize new types of emoms based on two dimensional (2d) multiple layered atomic structures (m-emoms). this research utilizes the structural **diversity** of mofs to unlock their full potential in advanced electronic and electrochemical devices. the pi and his team also partner with the materials research science and engineering centers (mrsec) education group and the institute for chemical education (ice) at university of wisconsin-madison to organize **make mofs at home?** after school enrichment program. through the integrated education plans, middle schoolers get hands-on experiences in synthesizing mofs using safe, daily accessible materials to foster their interests in stem, and undergraduate and graduate students receive interdisciplinary training in materials science, chemistry, and fabrication of energy storage devices.

**technical summary** the compositional **diversity** and synthetic tunability of metal-organic materials (mofs) give them great potential for a series of applications where precise tuning of structures and functionalities plays a vital role. integration of electronic properties (e.g., electronic conductivity) into mofs is of particular interest as it adds diverse functionalities on top of electronic properties, which greatly enriches the class of current electronic materials and the scope of their applications. however, the majority of mofs are insulators with just a few exceptional examples, most of which adopt single atomic layered p-d  $\pi$  conjugated 2d structures. this nsf career project develops new classes of electronically conducting mofs, called emoms through assembling multi-atomic layered 2d structures with p-d  $\pi$  conjugation, namely m-emoms. the metal species and organic ligands are systematically micro-tuned to manipulate the electronic characteristics and functionality of m-emoms. kinetically controlled synthetic methodologies are adopted to achieve highly crystalline m-emom products for precise measurement of their intrinsic properties. this permits

elucidation of fundamental aspects of interactions between the metal and organic building units and the subsequent impact on the bulk electronic properties. in turn, this research is poised to enable applications in various areas, including electrocatalysis and flexible electronic devices. this work not only provides a new platform to integrate metals with organic building units but also introduces new 2d material candidates with vastly expanded molecular engineering potential. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: CAREER: Probing and Exploiting Short-range Order in Crystalline Materials for Fast Ion Transport

Awardee: University of Utah

Amount: \$397,311.00

Abstract: this award is funded in whole or in part under the american rescue plan act of 2021 (public law 117-2). non-technical summary: fast ion conductors are major players in energy storage, a strategically critical area for the holy grail of vehicle electrification and the best solution to the intermittent and random nature of many renewable energy sources, such as solar and wind. past research has heavily focused on ion conductors with perfect prototype structures. as a result, further materials discovery was limited to incremental improvement and a narrow range of chemistry. in this project, with support from the solid state and materials chemistry program in the division of materials research, the principle investigator investigates structurally-disordered ion conductors with compositional flexibility that can potentially alleviate the industry's reliance on any single critical metal source which has broad societal impact. the project also integrates education and research to increase enrollment, **\*\*diversity\*\***, and retention of stem students, creating america's future stem workforce. in pursuit of these goals, the pi creates demonstration kits for college teaching and k-12 outreach, a crystal growth course with hands-on research-based activities, and a novel augmented reality experience for interactive crystallography pedagogy. the pi collaborates with the utah stem action center to reach students from backgrounds underrepresented in stem and school districts historically underperforming in stem and deliver them the kits and demonstrations. technical summary: the facile transport of ions in crystalline materials enables key functionality in various devices, such as batteries, membranes, and fuel cells. the structural characterization of these materials, however, presents an outstanding challenge. their crystal structures often exhibit short-range order, whereas traditional diffraction-based techniques are only sensitive to long-range periodic features. as a result, past research either had to ignore it for lack of instrument sensitivity or avoided it completely for fear of complexity and unpredictability. this career project, supported by the solid state and materials chemistry program in the division of materials research, overcomes these difficulties by performing state-of-the-art synchrotron and neutron scattering on judiciously selected

ion conductors, to precisely characterize these structural subtleties in both the mobile ion and the framework sublattices. the project also systematically modifies the chemistry and synthesis variables and correlate these parameters with structural observations and property measurements to reveal previously overlooked structure-property relationships. these insights enable the design of disruptively new materials with fast ion transport and excellent economic sustainability. the pi also engages in a series of education and outreach activities by taking an approach centering on research-based, hands-on activities, to reinforce cognitive knowledge and retention and stimulate students' interest in higher stem education and careers. specific efforts include: (1) outreach to middle and high schools with stem activity kits; (2) expansion of the hands-on lab sessions in a crystal growth course; and (3) creation of an augmented reality app for interactive crystallography pedagogy. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Continuous Twisted Nano-fibrous Yarns for Smart Piezo-Textiles

Awardee: Arizona State University

Amount: \$397,113.00

Abstract: clothing, after food, is perhaps the most common human essential, and textiles are a basic aspect of human life that has not changed from their "passive" form for many decades. current fabrics are made of passive materials such as nylon and cotton. the goal of this project is to investigate scientific foundations to realize controllable, and reproducible production of functional smart fabrics from nano-sized smart (piezoelectric) polymer yarns, and their integration with conventional fabrics. applications of smart textiles could include power generation and storage, personal protection, sports, fashion, communication, medical and physiological monitoring applications, and the internet of things. in particular, smart piezoelectric fabrics can be used for mechanical energy harvesting, for thermal energy harvesting through the pyroelectric effect, for

ferroelectric applications, as pressure and force sensors, for motion detection, and for ultrasonic sensing. smart fabrics will have the ability to react to different physical stimuli (mechanical, electrical, thermal, etc.) and as such can interact (sense, respond, communicate, and/or adapt) with their environment. this project will address the following challenges to realize smart piezoelectric polymer fabrics: development of processing and scale-up fabrication capabilities for production of continuous (weavable, knittable, and sewable) piezoelectric yarns; significant improvement in their electromechanical conversion efficiency; and design strategies for integration and packaging of piezoelectric yarns with conventional and conductive threads. the educational objective of the project is focused on increasing the **\*\*diversity\*\*** in nanotechnology-stem through summer programs for high school students. these students will be trained on nanotechnology research, in particular smart fabrics made of piezo nanofibers. in this project, a manufacturing process based on continuous electrospinning is proposed that enables continuous production of twisted yarns. a major obstacle in the utilization of piezoelectric polymers for smart fabric applications has been the low electromechanical conversion efficiency of piezo polymers (~2%) compared to the piezo ceramics (~50%), which are inherently brittle and not suitable for smart fabric applications. the scientific outcomes of this research will be the inter-relation of thermomechanical processing, percentage of crystallinity, and orientation of crystallites and elastic and piezoelectric properties of the piezoelectric nanofibers and twisted bundles. through fabrication and processing steps combined with computational analysis, the project will produce polymer yarns with significantly enhanced piezoelectric efficiency. this will be achieved through thermomechanical processing (thermal annealing, and drawing) designed to control the morphology (percentage of crystallinity, and orientation of crystallites), and hence properties (elastic and piezoelectric properties) and performance and output power under various external loads of piezoelectric polymer fibers. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: CAREER: An integrated study of wave-particle interaction on liquid interfaces

Awardee: University of North Carolina at Chapel Hill

Amount: \$396,909.00

Abstract: this career project will investigate how millimeter-size particles move and interact on the surface of a vibrating fluid. understanding the interplay between small particles and liquid surfaces is a broad area of research with many applications, including the transport and removal of floating litter and aerosol generation from rain drops merging with the sea surface. most of the studies available in the literature focus on situations involving either a single particle impacting on a liquid surface or multiple floating particles. however, an interesting regime, which has received much less attention, emerges when the underlying liquid bath is vibrated vertically. in this case, small droplets may bounce and even "walk" along the liquid interface as they interact with surface waves caused by rebounds. the goal of this project is to demonstrate new dynamics that characterize this intermediate

regime. the investigators will combine experiments and theory to study new bouncing and walking modes, behaviors of groups of interacting particles, and new transport effects emerging from the interaction between bouncing particles and submerged features. this project will provide new multidisciplinary research experiences and educational modules for high school, undergraduate, and graduate students. the investigators will develop a new course that interweaves rigorous mathematical training with direct exposure to realistic research settings. this project will also develop specific initiatives to instill strong communication skills in the trainees, including a dedicated bootcamp for students to develop expertise in the art of scientific visualization. the communication and visualization efforts will be leveraged to promote **\*\*diversity\*\*** in stem through a range of outreach events. this project will develop new experimental techniques and mathematical models to generate a fundamental understanding of the interaction between capillary-size particles and a vibrating liquid interface. in 2005, yves courder and co-workers discovered that a millimetric liquid drop can spontaneously walk along the surface of a vibrating fluid bath, self-propelled through a resonant interaction with the waves created when it strikes the fluid surface. by virtue of the coupling with their wave fields, these walking droplets, or "walkers", exhibit surprisingly rich dynamics, including complex bouncing modes, bound states, and dual wave-particle behaviors. this project will extend and exploit the remarkable walker dynamics for fundamental research relevant to practical settings involving granular materials on liquid interfaces. the investigator will first focus on broadening the current parameter regime of bouncing and walking dynamics to include new combinations of fluids and solid particles of different shapes. the second aim will be to investigate new self-assembly and collective dynamics with large ensembles of walkers coupled by wave-mediated forces. the final aim will be to examine the interaction between walking droplets and submerged features at the bottom of the liquid bath, including periodic and disordered bottom topographies. this class of problems will lead to a better understanding of the interplay between particles and liquid interfaces, and offer design principles for the development of new methods of self-assembly, particle sorting, and transport of granular materials on liquid interfaces. this award

reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: IRES Track II - Cape Horn ASIs: Climate change and disease ecology at the southern end of the Americas

Awardee: University of North Texas

Amount: \$396,610.00

Abstract: over sixty percent of earth's ice-free areas are best described as human-modified anthropogenic biomes. this means that pristine areas are scarce, and that most ecological studies are de facto studies of anthropogenic impacts on ecological systems. however, the study of pristine systems is necessary for developing a baseline understanding of ecological function so that we can apply this understanding to develop meaningful and appropriate conservation plans, or even know what applied research questions are worth pursuing. unfortunately, pristine systems are at a premium. in general, graduate students do not have the opportunity to develop their ecological understanding under pristine or near pristine ecological systems. in addition, the national academy of science, engineering and medicine data suggest that current stem graduate student training may not be providing a rigorous education in quantitative experimental design. quantitative experimental design is designing studies with an eye toward the statistical analyses that will be used to analyze the data. using quantitative design principles, rooted in sound ecological theory, ensures that researchers are asking relevant and testable questions that will lead to meaningful results. this is a crucial component of graduate student education and researcher professional development, as it ensures that increasingly scarce research funding are not wasted additionally, collaboration is becoming the norm in research, and international collaboration via electronic media was becoming increasingly common even before the current pandemic. in this ires track ii project, students will have the opportunity to be trained in quantitative experimental design and work as part of a

multinational research collaboration to study infectious disease emergence in one of the few remaining pristine places on earth. the cape horn biosphere reserve (chbr) off the southern tip of south america protects pristine ecosystem is perfect for this type of graduate student training. the chbr is part of the sub-antarctic magellanic ecoregion, which is globally significant because it houses the worlds southernmost forest biome, contains numerous endemic species, is remote, and is relatively free of anthropogenic impacts. in addition, with the exception of avian malaria which arrived just a few years ago, the system is relatively free of zoonotic diseases. making the region a living laboratory to study the ecosystem transformations that co-occur with human discovery and settlement of an area. the program will bring graduate students from across the us to work in international collaborative teams with chilean students from the universidad de magallanes (umag) and the institute of ecology and bio\*\*diversity\*\* (ieb) in chile, and a diverse group of faculty from across the us and chile. the focus of the program will to be provide graduate students robust and hands-on training in quantitative experimental design and international collaboration resulting in publications. the research questions themselves will be flexible, but organized thematically. specifically, this ires track-ii will focus on the merging molecular genetic analysis using a mobile next generation sequencing lab with mist netting and arthropod trapping to investigate the impacts of wildlife disease on local bio\*\*diversity\*\* and community structure. secondarily, edna and traditional wildlife disease monitoring approaches will be applied to understand the potential for zoonosis and understanding ecological factors that contribute to, or inhibit, zoonosis. resultantly, participation in this program will help train the next generation of scientists with the skills needed to make meaningful contributions to the study of ecology, conservation, and wildlife disease ecology. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: IntBIO Collaborative Research: An integrative approach for projecting insect responses to a

rapidly changing climate

Awardee: Board of Regents, NSHE, obo University of Nevada, Reno

Amount: \$396,542.00

Abstract: projecting species' responses to climate change at continental scales is a current 'grand challenge' of ecological research. insects are sensitive indicators of both climate and land-use change and recent studies indicate widespread declines in many geographic regions. to predict changes across entire ranges, a variety of species distribution models have been developed, but rarely account for regional variability, ecological interactions or a species' potential to adapt to changing conditions. this project spans multiple institutions situated in the united states' southwest, polar north, and temperate eastern regions. a series of physiological experiments will be implemented for five widespread butterfly species with populations sourced from different biomes within each of their ranges. caterpillars will be subjected to a range of conditions mimicking past, current and future climates. their development rate, survivorship, immune response, and genetic structure and gene expression (which genes are actively coding for proteins) will be measured and used to build models that predict distributional shifts. data collected by community ('citizen') scientists will be used to validate the models. this project requires substantial cross-disciplinary collaboration, and a central goal is to recruit diverse trainees at the graduate and undergraduate levels and train them in the 'science of team science'. project trainees will develop independent research ideas that align with and expand the project's scope and travel between and work at collaborating institutions as an inter-lab exchange to learn new techniques and be exposed to different research philosophies. finally, the project has significant management implications for insect bio\*\*diversity\*\* conservation. projecting responses to climate change at continent scales is a current 'grand challenge' of ecological research. insects are the most diverse and ecologically important terrestrial animal taxon and are strongly affected by climate change. to predict changes, species distribution models (sdms) have been widely implemented across many taxa. sdms, however, rarely account for ecological interactions, plasticity or evolutionary adaptive potential owing

to the extensive physiological and ecological data required to parameterize such models. the biology of lepidoptera, particularly butterflies, is extremely well observed, thus it is logistically feasible to build upon past knowledge and collect additional data that enables mechanisms to be more seamlessly integrated into sdms. multiple populations for each species will be sourced from different biomes across its range. caterpillars will be reared in common gardens under a range of temperature conditions mimicking past, current and future climates. their development rate, survivorship, immune response, genetic structure and gene expression will be measured and used to build models that predict future distributions. distribution data collected by community (?citizen?) scientists will be used to validate and improve models and allow robust estimates of uncertainty. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: CAREER: Electrochemical Dynamic Midinfrared Metasurface for Ultra-Low Power Wearable Thermoregulation

Awardee: Duke University

Amount: \$396,513.00

Abstract: thermal comfort is one of the most essential fundamental needs for human health and productivity. the seasonality of cardiovascular diseases and influenza demonstrates the importance of stabilizing our thermal environments. however, because of its necessity, indoor temperature control is also associated with enormous energy consumption and carbon emission. this proposed work aims to break the health-energy dilemma by developing a wearable radiative thermoregulation device that can localize heat management around the human body. like a chameleon that can change its visible color, the wearable device can act like a second skin that changes the level of radiative heat loss into the environment to offset the adverse ambient temperature change. the thermal radiation is tuned by an electrochemical reaction that uses less than 1 v as operation voltage. this working principle is similar to a battery but with the focus on its mid-infrared optical property change. like a battery that can maintain its state of charge for a long time, the device can also maintain its heating/cooling state with ultralow energy consumption, which is orders of magnitude more efficient than traditional active devices such as electric blankets. to promote **\*\*diversity\*\***, equity, and inclusion, the project will organize the annual workshop series called lite (light, infrared, and thermal energy) for underrepresented students by collaborating with the step up to stem program at north carolina school of science and mathematics. the workshop series aims to inspire high schoolers' interest in photonics, thermal science, and general stem fields by providing introductory lectures and immersive hands-on experiments such as thermal vision vr goggle diy sessions. in photonic technical terms, the device adopts a metal-insulator-metal configuration and the working principle of a midinfrared metamaterial perfect absorber. it uses electrochromic conjugated polymer, such as polyaniline, as the active material. by electrochemically biasing the

polymer, its carrier density, plasmon frequency, and permittivity are tuned dynamically and reversibly, thus varying the device state between a metamaterial absorber and a simple metallic reflector, which is equivalent to emissivity tuning based on the kirchhoff's law of thermal radiation and the zero transmittance. this project will involve multiscale and multidisciplinary study in materials science, photonics, heat transfer, and wearable device engineering. specifically, the project will develop the correlation among polymer synthesis condition, structural characterization, charge transport measurement, mid-infrared permittivity, metamaterial absorber designs, and heat transfer measurement. the proposed research will scale up the adaptive metamaterial absorber and implement kirigami paper cutting technique to provide stretchability, breathability, and conformal deformability from 2d thin film to 3d shapes for wearable applications. the wearable metasurface thermoregulation will further advance the emerging field of multimodal and multispectral light and heat management for the health-energy nexus. the in-depth study of electrochemically active polymers will also become an enabler for adaptive optical metasurfaces, sustainable energy science, and personalized preventive medicine. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Phase Transformation and Proximity Coupling in Lateral Heterostructures of Metal Dichalcogenides

Awardee: Michigan State University

Amount: \$394,948.00

Abstract: two-dimensional (2d) materials are atomically thin with atoms strongly bonded within layers but weakly between layers. this weak interlayer coupling allows for the vertical stacking of different materials to form heterostructures with interesting properties and applications. in contrast, a lateral heterostructure consists of different 2d materials placed side by side with one-dimensional

boundaries with strong bonding. the difference is akin to a stack of different plates (vertical) vs. being spread out on a table (lateral). this project will investigate novel phenomena that arise in lateral heterostructures with exposed boundaries on the surface. this allows for spatially resolved exploration of new interfacial physics and the rational design of heterostructures with desired properties. for example, the pis have previously demonstrated that they can convert a 2d material from a semiconductor to a topological insulator. the latter is a state of quantum matter that behaves as an insulator in its interior but as a conductor on its surface. coupling a topological insulator with a superconductor may give rise to topological superconductivity, which can be used for quantum computers. this project also aims to providing training ground for a competitive workforce in materials research. the pis will strive to enhance the **\*\*diversity\*\*** of this workforce by actively recruiting and mentoring female and minority students. research-based educational materials are to be integrated with outreach activities to engage the public. the rapid advances in two-dimensional (2d) materials enable the integration of atomically thin layers with vastly different properties into heterostructures, where exotic behaviors that are not accessible in individual layers may emerge. most studies of 2d heterostructures have been pursued on vertical geometries to take advantages of van der waals interaction for creating a passivated interface with low density of interfacial electronic states. in contrast, lateral heterostructures uniquely allow for the heterointerfaces, which are typically buried in the bulk, to be directly exposed on surface for unravelling boundary-induced behaviors by scanning probe techniques. the pi aims to explore the versatility of phase transformation scheme empowered by the core-shell lateral architecture and apply the proximity studies to transition metal dichalcogenides (tmDCs) with correlated electronic behaviors. the local perturbations associated with the lateral boundary could provide the knob to tune the interactions and thus facilitate the understanding of collective electronic states as well as their interplay in the monolayer regime. this research also aims to address the feasibility of applying lateral heterostructures to induce topological superconductivity on the edge of 2d topological insulators. it sheds light on the investigation of majorana physics using lateral templates of 2d materials, holding potential to implement topological

qubits in fault-tolerant quantum computation. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: REU Site: MURALS (Materials-focused Undergraduate Research Applied to the Life Sciences) at UMass Amherst

Awardee: University of Massachusetts Amherst

Amount: \$391,761.00

Abstract: this award is funded in whole or in part under the american rescue plan act of 2021 (public law 117-2). non-technical summary this reu site offers research opportunities for 10 undergraduates each summer at the university of massachusetts amherst (umass amherst). this reu site is unique in that it will give students training in how to create advanced materials and how to use these materials to tackle grand challenges in biology. students work in laboratories at the biology/materials interface, take part in both professional development and technical training provided by the reu site, and learn from near-peer and lab mentors to guide student career development. the site has outstanding mentors from leaders in the field from both chemical engineering and biomedical engineering at umass amherst. all labs are physically and intellectually connected through the institute for applied life sciences at umass. industry site visits and entrepreneurial outreach activities help expose students to potential career opportunities in biotechnology. partnership with the other professional development programs at umass supports recruitment and mentoring of reu students across all backgrounds to ensure everyone has an equal opportunity to research opportunities at umass. recruiting efforts at several minority-serving national conferences, as well as partnerships with minority-serving institutions via the \*\*diversity\*\* office in the college of engineering at umass ensures opportunities for students from traditionally underrepresented groups in stem. evaluation efforts track the long-term outcomes for students from

these groups.        technical summary        this is a new reu site (murals: materials-focused undergraduate research applied to the life sciences) at umass amherst, developed to offer research opportunities for 10 undergraduates each summer, broadly in the area of materials for bioengineering applications. the pi of this reu site, prof. shelly peyton, is an expert in bioengineering, with a focus on applying biomaterials development toward solving complex problems in biology. this site has 10 host laboratories, with faculty from the chemical engineering and biomedical engineering departments at umass amherst, who are both physically and intellectually connected through the institute for applied life sciences at umass amherst. the overarching objectives of the murals reu site are to: 1) recruit and encourage students from traditionally underrepresented groups in engineering to do research at the interface of materials and the life sciences; 2) inspire students from all backgrounds to pursue graduate studies and/or professional careers at the interface of materials and the life sciences; 3) train students to be effective scientific communicators, through carefully planned workshops on writing, presentation skills, and working amongst diverse groups of scientists; 4) integrate reu students within the broader scientific community at umass amherst by pairing students with peer mentors outside the lab; 5) allow students to explore their interests in entrepreneurship, through a partnership with the technology development office within ials, the biotechnology training program (btp) at umass, and industry site visits; 6) provide students with professional development workshops and tools (e.g., career choices, ethics in research, interviewing strategies, time management) to instill the techniques to succeed in any industry long after they leave murals. recruiting efforts at several minority-serving national conferences, as well as partnerships with minority-serving institutions via the \*\*diversity\*\* office in the college of engineering ensure opportunities for students from traditionally underrepresented groups in stem. evaluation efforts track the long-term outcomes for students from these groups.        this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Proposal: NSF-DFG Echem: Understanding the Mechanism of Urea Oxidation on Nickel-Based Electrocatalysts

Awardee: University of Washington

Amount: \$391,583.00

Abstract: urea is a common high-nitrogen chemical waste product of mammalian metabolism, and a major component of fertilizer runoff poses significant threat to water resources from agricultural runoff and municipal wastewater. A promising means for removing excess urea is to oxidize it electrochemically to produce harmless compounds. Urea removal processes can also be used to generate electricity and to produce hydrogen for fuel cells. Electrochemical urea removal therefore exhibits strong potential as a transformative technology by converting a harmful waste product to the benefit of society, industry, and the environment. The project brings together researchers from the United States and Germany to apply a synergistic blend of experimental and theoretical methods to the study of electrochemical urea removal from water. In particular, the project seeks fundamental understanding of catalytic urea oxidation that is needed to develop feasible urea removal technologies. Effective urea removal systems are key to a large number of technological applications including municipal and agricultural wastewater treatment, remediation of fertilizer runoff, ammonia synthesis, hydrogen production, and electricity generation. Other benefits from this project will include workforce development and educational outreach to underrepresented grade-school students. These efforts will promote increased diversity in STEM fields, a student exchange program between Germany and the US, and improved scientific literacy of the general public. The goal of this research project is to develop comprehensive knowledge of electrochemical urea removal over nickel-based catalysts, based on experimental and theoretical research spanning molecular and device levels. Electrochemical urea removal will be studied by density functional theory calculations, vibrationally and electronically resonant sum frequency spectroscopy, and electrochemical measurements of reaction rate and product distributions. Particular attention will be

paid to the active form of the nickel oxide electrode as it exists in different phases and oxidation states depending on electrode potential and history, such as aging and preparation method. this combined electrochemical, spectroscopic, and computational approach provides insight related to catalyst structural changes and how they affect the urea reaction mechanism, reactivity, and effectiveness of nickel, nickel-iron, and nickel-chromium catalysts. the outcomes of this research will greatly advance the scientific understanding of electrochemical urea removal -- about which little is known -- and establish a foundation in the wider field of electrocatalysis regarding electrochemical reactions on oxide surfaces and on surfaces that undergo a change in oxidation state as part of the overall reaction mechanism. successful completion of this research will benefit society through sustainable methods for treating wastewater and agricultural run-off that will reduce demand on water supply systems and enhance the bio\*\*diversity\*\* of marine ecosystems. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Mechanics of Crystallization, Deformation and Phase Transformation in Granular Materials with Engineered Grain Geometries

Awardee: University of Colorado at Boulder

Amount: \$391,525.00

Abstract: this grant will focus on the engineering, modeling, fabrication and testing of new types of solid granular materials. granular materials like sand are seemingly simple, but their mechanics is remarkably rich and complex. in this project, the geometry of individual grains will be manipulated to generate crystallization and deformation mechanisms not seen in traditional granular materials, creating ?granular materials by design?. this project will establish a mechanics-based fundamental understanding of crystallization in granular materials, enabling manipulation and assembly at large scales. this project will also generate mechanics-based models for the inelastic deformation of

granular crystals based on contact mechanics and geometrical hardening. the new granular materials that will emerge from this work will have high strength, unique combinations of assembly / disassembly, strength and self-healing, making them attractive as lightweight materials and aggregate architectures. the reversible nature and the large deformation capabilities of these granular materials will also make them attractive as shape morphing materials, programmable ?smart? matter, robotics and biomedical materials. vigorous outreach activities will be developed in this project including curriculum development at the university of colorado, research projects for undergraduate students, active learning module for high school students, as well as promotion and improvement of **\*\*diversity\*\*** in stem. a major scientific objective for this project is to create a unified and mechanics-based framework that captures the assembly, phase transformations, deformation and failure of engineered granular materials. granular systems of specific interest and critical scientific questions include: (i) high packing and space filling in ?granular crystals? with stiffness and strength orders of magnitude higher than traditional granular materials; (ii) steering of grains through amorphous-crystalline transitions using mechanical stimuli; (iii) effects of confinement and unlimited deformations to create and control attractive functionalities such as shape morphing, healing, tuning of stiffness and strength; (iv) mechanics of interlocking in branched particles to generate high strength and toughness in tension. methods include discrete element modeling using geometry-sensitive contact algorithms, 3d printing of grains, and mechanical experiments with in-situ 3d imaging (refractive index matching scanning). a fundamental understanding of these new ?engineered? granular materials will lead to new paradigms for the manufacturing and mechanics of granular materials and structures, and for the generation of advanced functionalities such as adaptability, shape morphing or self-healing. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: GCR:Can improved ecological forecasting accelerate sustainability transformation in urban lighting?

Awardee: Colorado State University

Amount: \$389,774.00

Abstract: achieving national sustainability goals will require rapid adoption of more sustainable practices in many areas of society but transitions to sustainable practices are often slow. this project tests whether these transitions can be accelerated by (1) creating innovative ecological forecasts that predict where and when more sustainable practices would have the greatest benefits and (2) engaging impacted communities in the process of co-implementing forecasts and advocating for sustainability transitions. the study system is the proliferation of artificial lights at night (alan) and its impacts on migrant birds. alan is increasing rapidly worldwide, and its benefits are countered by pervasive negative consequences for bio\*\*diversity\*\*, ecosystems, and human health. a major ecological consequence of alan is disruption of bird migration ? millions of birds die annually in collisions with well-lit buildings ? which contributes to widespread bird population declines. the alan-bird migration system is ideal for this study because, like many wicked environmental

problems, environmental concerns emerge as a product of complex social and cultural processes that have proven difficult to resolve using traditional approaches. this project employs a transdisciplinary convergence approach to integrating advances in ecological forecasting with those in the social and political science of community engaged scholarship. experiments testing sustainability impacts of innovations in ecological forecasting will be co-designed and implemented with a coalition of convergence research partners. the project will generate an understanding of pathways by which sustainable practices are adopted for alan, this new knowledge can be used to help address other societal-environmental conflicts. the project focuses on testing a key prediction of sustainability transformations science theory ? that innovations originate within advocacy coalitions then accumulate at the subsystem level to drive sustainability transformations (e.g., new policies). during phase one the investigation gathers detailed national survey information on the alan system and creates transformational technological improvements in existing bird migration forecasts specific to impacts of alan. this new social and ecological knowledge will then be used to engage with advocacy coalitions in specific urban testbed sites to co-implement sustainability transformation experiments during phase two. these experiments will use targeted messaging campaigns to foster alan mitigation. experiments will be focused on sustainability-oriented coalitions because these advocates are predicted to have high leverage to affect radical transformation toward sustainability across the alan subsystem. impacts of the experiments on alan, impacts of alan on migrant birds, and human behaviors and attitudes toward alan will be quantified. through this two-phase approach this project will produce a new understanding of how innovations derived from a convergence research approach can be employed in a sustainability science and policy framework to accelerate transformations. these outcomes will contribute understanding of how communities and researchers can co-engage with wicked environmental problems more broadly to drive transformations toward sustainability. results will create new, and potentially transformative, understanding of how ecological forecasting contributes to sustainability transformations. this project is jointly funded by the growing convergence research program and the established program to stimulate competitive

research (epscor). this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: BPC-AE: STARS: Catalyzing Action-Oriented Academic Communities for Broadening Participation in Computing

Awardee: Kent State University

Amount: \$388,484.00

Abstract: it is critical to address the longstanding issue of underrepresentation of women, black, and hispanic students in computing degree programs to provide an equitable foundation for all to participate in our society and the global economy as controllers and creators of technology, and to advance the preparation of a diverse, innovative, and competitive tech workforce. building on the prior success of the stars computing corps alliance for broadening participation in computing, the goal of the stars catalyst project is to: 1) increase the number of women, black, and hispanic students that persist in computing degree programs, and 2) advance the careers of students and faculty from groups that have been historically underrepresented in computing. through research and evaluation around stars catalyst activities, this project will advance knowledge about practices designed to increase persistence and support career advancement in computing for college computing students and faculty, particularly for those from underrepresented and intersectional groups in computing. the stars catalyst alliance is a collaborative effort across temple university, north carolina state, kent state, florida state university, morgan state, and university of north carolina charlotte. the stars computing corps alliance for broadening participation in computing (bpc) engages computing faculty and students at colleges, universities, and community colleges in a community of practice with a shared commitment to take action to advance **diversity**, equity, and inclusion in computing. stars computing corps conferences, communities, and networks create

significant institutional and human resources that can expand bpc research to a larger audience of researchers, educators, administrators, cs departments, and k-20 students, and can dramatically increase the number of people taking action in bpc efforts. prior results show that the stars computing corps alliance increases intentions to persist in computing among stars students and faculty, with enhanced outcomes for black students and faculty. this project will significantly extend the stars alliance to expand upon those impacts, by 1) including new partners that expand the reach of stars and that emphasize participation of black and hispanic students and faculty, particularly from emerging hispanic serving institutions and community colleges, 2) creating new program elements that test new and propagate evidence-based bpc practices within computing departments, and 3) leveraging partnerships to support identity-focused affinity groups, and 4) developing stars alumni groups employed in industry positions to promote transition to and retention within the tech workforce. extensions to the stars leadership corps program, stars launch program, and the stars celebration conference will serve to develop and propagate evidence-based approaches aimed at improving the teaching and learning of computing for black and hispanic students and build evidence of their effectiveness, and the respect research conference will continue to advance peer-reviewed bpc scholarship. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: CAREER: Achieving Real-Time Machine Learning with Sparsification-Compilation Co-design

Awardee: College of William and Mary

Amount: \$388,400.00

Abstract: machine learning (ml), particularly deep learning (dl), has gained great success in recent years, especially with the use of deep neural networks (dnns) of different types. varied dnns serve as the state-of-the-art foundation and core enabler of many key applications, such as robotics, high-quality video stream processing, augmented reality, wearable devices, smart health devices, etc. achieving high accuracy typically requires dnns with large and complex model structures, which also translates into high computing requirements for both training and inference steps. accelerating the training process on a modern high-performance computing (hpc) node or cluster and inference process on a lower-end power-efficient device have both emerged as major challenges. this project focuses on this problem, viewing dnn training and inference as hpc workloads that need to exploit available multi-level parallelism, complex memory hierarchy, and device heterogeneity; while automating the optimizations through a compiler. if this project succeeds, it will, for the first time, enable real-time machine learning for many edge devices, enabling the greater success of ml-based end applications that are important for the society, economy, and other science and engineering areas. this project will also make several contributions towards both education and improving

**\*\*diversity\*\***, including: (1) introducing hpc in an ml course, and ml workloads optimization experience in both undergraduate systems and graduate research courses, particularly with interesting demonstration videos; (2) outreaching to undergraduates with the goal of creating interest in (systems) research, and to k-12 with the goal of attracting underrepresented groups to computer science.

the key idea of this project to address the above challenge is sparsification-compilation co-design. it first introduces a general sparsification idea called fine-grained structured pruning, which prunes the weights according to certain fine-grained structures and preserves non-zero weights in a more regular way. based on this idea, this project designs a high-level abstraction called layer-wise intermediate representation (ir) to capture the sparsity information with the goal of enabling aggressive compiler optimizations. building on a successful application of this idea on two-dimensional dnns, this project undertakes a comprehensive agenda to fully apply the benefits of this approach. first, it unifies convolutional neural networks and recurrent neural networks acceleration with a more general fine-grained structured pruning instance and a set of enhanced compiler-based automatic optimizations. second, it improves the pruning or retraining process itself by extending the compiler optimizations from inference to pruning and exploiting domain properties to carry-out optimized application-level checkpointing. third, it extends the (compiler automated) optimization framework to support high-dimensional and extremely deep dnns. finally, it explores data reuse across dnns for situations where multiple dnns are co-executed on the same device.

Title: Collaborative Research: Does Cytonuclear Coevolution Drive Reproductive Isolation?  
Dissecting the Architecture of Genetic Incompatibility Across a Species Range

Awardee: James Madison University

Amount: \$386,265.00

Abstract: the natural world exhibits a vast array of bio\*\*diversity\*\* which ensures the stability of ecosystems, the services they provide, and has intrinsic aesthetic value. individual species are critical elements of this bio\*\*diversity\*\* and understanding how new species form is key to ensuring maintenance of \*\*diversity\*\*. interactions between the nuclear genome and organelle (mitochondria and chloroplast) genomes underlie key processes including respiration and photosynthesis. these interactions are an underappreciated and yet potentially powerful driver of the earliest stages of speciation. the planned research will investigate the contribution of intergenomic interactions to incompatibility between populations of a species. the research will use state-of-the art techniques to identify the genomic basis of incompatibility between the nuclear and organelle genomes and determine the ability of such incompatibility to maintain genetic divergence and facilitate speciation in a contact zone. the project will also introduce undergraduate students and high-school and community college teachers to core ideas about species formation and evolution through hands-on experience with the newest genomic sequencing technologies in a novel course-based lab module and workshop. finally, the project will provide training at the undergraduate, graduate, and post-graduate level. interactions between cytoplasmic and nuclear gene products are expected to drive intergenomic coevolution, leading to the potential for genetic incompatibility and reproductive isolation between populations with divergent cytoplasmic genomes. while such cytonuclear incompatibility (cni) has been posited to be among the earliest reproductive barriers to develop during speciation, our understanding of the dynamics of cni at the early stages of speciation remains limited, particularly for plastid-driven speciation. the research will examine the dynamics of plastid driven cni in *campanula americana*, creating a powerful set of genomic resources, characterizing variation in the genetic architecture of cni across lineages, and leveraging a natural contact zone to evaluate whether exposure to selection alters the genetic architecture of cni relative to allopatry. together, these data will provide insight into the evolutionary dynamics of plastid-nuclear incompatibility and how these dynamics may drive the early stages of speciation. this award

reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: REU-Site: Regional Initiative to Promote Undergraduate Participation in Experimental and Computational Materials Research

Awardee: University of Alabama at Birmingham

Amount: \$384,789.00

Abstract: non-technical summary: this award is funded in whole or in part under the american rescue plan act of 2021 (public law 117-2). the university of alabama at birmingham (uab) in partnership with historically black colleges and universities (hbcu?s) in alabama will host a research experiences for undergraduates (reu)-site in experimental and computational materials research. this reu-site project plans to recruit students from underrepresented groups and academic institutions where research opportunities are limited. this project offers a broad range of interdisciplinary materials research experiences to undergraduate students with a **\*\*diversity\*\*** of backgrounds in physics, chemistry, applied mathematics, and engineering. the undergraduate students will gain experience in materials synthesis, materials characterization and computer modeling and simulations during their ten-week research stay at the uab campus. the scientific research projects have been specifically developed for undergraduate students by an interdisciplinary team consisting of science and engineering faculty at uab. this project will continue to provide lecture series and workshops in materials growth and characterization, research ethics and professionalism, innovation and entrepreneurship and preparation for graduate school to all participants. the reu participants will publish their findings in peer-reviewed journals and/or present at professional meetings leading to a broad dissemination of new knowledge created in the undergraduate research projects. this reu-site plans to develop a pipeline of undergraduate researchers who will become leaders in advances in science and discovery of novel materials and contribute to economic development and national defense. technical summary: reu-research projects are organized in four research clusters: (1) materials under extreme conditions (2) machine

learning and simulations in materials research, (3) infrared lasers and spectroscopy, and (4) polymeric biomaterials and capsules for drug delivery applications. the undergraduate research projects will contribute to fundamental understanding of phase transformations and degradation of materials under extreme conditions, machine learning enabled materials discovery, materials for mid-ir lasers and quantum information systems, and 3-d printed biomaterials and stimuli responsive polymers. some research projects will also involve the use of national x-ray synchrotron facilities and neutron diffraction facilities in materials research. the undergraduate student projects have short-term achievable milestones, while simultaneously contributing to longer-term scientific goals and technological applications. our teaming arrangement of reu-participants with faculty and graduate students, giving poster and oral presentations, writing a research-style paper, and attending training seminars in scientific communications and ethics will help reu students see the big picture of what it takes to develop into a research scientist with the critical skills needed for analyzing, interpreting, and presenting scientific data. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: REU Site: The Stressed Life of Cells

Awardee: University of Kansas Center for Research Inc

Amount: \$384,630.00

Abstract: this reu site award to the university of kansas, located in lawrence, ks, will support the training of 10 students for 10 weeks during the summers of 2022-2024. students will formulate their research plans with their mentors, spend the majority of their time on a research project, and will present their findings in a university-wide research symposium at the end of summer. the underlying aim is to provide students with a strong basis and incentive for pursuing careers in research, with a specific goal of increasing **\*\*diversity\*\*** and participation in the sciences. it is anticipated that a total of 30 students, primarily from schools with limited research opportunities, or from underrepresented groups, will be trained in the program. mentor-directed scientific activities will be performed in the department of molecular biosciences in faculty labs in the fields of biochemistry, cell, molecular and developmental biology, virology and microbiology, and computational biology. in the context of the common research theme of 'stress,' students will learn how environmental and biological conditions may affect development, function, and survival of cells and organisms, as well as the nature of stress response mechanisms. examples of student projects may involve use of genetically tractable organisms (drosophila, c. elegans) to model evolution of stress responses or neurological responses to stress, use of modified infectious agents (bacteria, coronavirus) in studies of host/pathogen interactions and mechanisms, and biochemical analysis of infection-associated strategies in microorganisms (t3ss, quorum sensing). weekly programs and social activities will

develop student career progression, foster independence as a scientist, hone presentation skills, and foster community. students will attend interactive workshops on responsible conduct of research, scientific writing, and applying to graduate school. assessments of the program will be performed using the salg urssa tool. program members and faculty will maintain continued communications with participants as they plan for conference presentations and prepare for graduate school, allowing their career trajectories to be assessed. participants should have completed freshman biology and chemistry, and must be u.s. citizens or permanent residents. more information about the program is available at mbreu.ku.edu, or by contacting the pi, dr. lisa timmons, at mb-reu@ku.edu. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: CNS Core: Medium: Data Augmentation and Adaptive Learning for Next Generation Wireless Spectrum Systems

Awardee: Auburn University

Amount: \$383,835.00

Abstract: deep learning has shown great promise in solving many open challenges in wireless networking research and applications. deep learning is data hungry, and one of the critical obstacles towards fulfilling its promise is facilitating the acquisition of sufficient amounts of data to train and validate deep learning models. the primary goal of this project is to devise innovative approaches that enable wireless researchers and practitioners to acquire data more efficiently at reduced cost and to utilize existing data more effectively. findings from this project are expected to fuel future breakthroughs in wireless research by making deep learning models more widely applicable. by integrating research and education, the proposed work will provide excellent hands-on exercises, research, and educational opportunities for undergraduate and graduate students at the three

collaborating universities. the project will leverage the existing **\*\*diversity\*\***-related outreach programs at the three institutions to broaden participation from under-represented groups. a team of four investigators with complementary expertise from auburn university, temple university, and california state university, sacramento will carry out a coherent research agenda consisting of the following four thrusts: (1) spectrum data synthesis and augmentation aided by generative adversarial networks; (2) exploiting historical and synthetic wireless networking data through novel transfer learning algorithms; (3) characterizing the relationship between dataset size and performance; (4) integrate, validate and apply approaches developed in the first three thrusts on spectrum database construction, rf spectrum anomaly detection, and transmitter classification. thrusts 1-3 are application-agnostic and focused on studying fundamental concepts and techniques that facilitate the acquisition of sufficient amounts of wireless data, enable more effective utilization of existing data, and enable the prediction of how much data is needed to meet desired performance. thrust 4 is application-specific and focused on specific wireless applications where deep learning has been applied and demonstrated great potential. the data, software and education materials developed from this project will be widely disseminated. the project will engage industry stakeholders on project-related issues, with the aim to disseminate ideas and learn relevant challenges faced by the industry when applying deep learning to wireless applications. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: FAI: Quantifying and Mitigating Disparities in Language Technologies

Awardee: Carnegie-Mellon University

Amount: \$383,000.00

Abstract: advances in natural language processing (nlp) technology now make it possible to perform many tasks through natural language or over natural language data -- automatic systems can

answer questions, perform web search, or command our computers to perform specific tasks. however, ``language" is not monolithic; people vary in the language they speak, the dialect they use, the relative ease with which they produce language, or the words they choose with which to express themselves. in benchmarking of nlp systems however, this linguistic variety is generally unattested. most commonly tasks are formulated using canonical american english, designed with little regard for whether systems will work on language of any other variety. in this work we ask a simple question: can we measure the extent to which the **diversity** of language that we use affects the quality of results that we can expect from language technology systems? this will allow for the development and deployment of fair accuracy measures for a variety of tasks regarding language technology, encouraging advances in the state of the art in these technologies to focus on all, not just a select few. specifically, this work focuses on four aspects of this overall research question. first, we will develop a general-purpose methodology for quantifying how well particular language technologies work across many varieties of language. measures over multiple speakers or demographics are combined to benchmarks that can drive progress in development of fair metrics for language systems, tailored to the specific needs of design teams. second, we will move beyond simple accuracy measures, and directly quantify the effect that the accuracy of systems has on users in terms of relative utility derived from using the system. these measures of utility will be incorporated in our metrics for system success. third, we focus on the language produced by people from varying demographic groups, predicting system accuracies from demographics. finally, we will examine novel methods for robust learning of nlp systems across language or dialectal boundaries, and examine the effect that these methods have on increasing accuracy for all users. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Adaptive Optics Astrometry for Black Hole Science

Awardee: University of California-Berkeley

Amount: \$380,062.00

Abstract: black holes are one of the most exotic phenomena in astrophysics and represent a breakdown in fundamental physics between gravity and quantum mechanics. at the center of our galaxy, a supermassive black hole was discovered thanks to high-precision astrometric observations from the world's largest telescopes ? a discovery awarded the nobel prize in 2020. in addition to the central black hole, the milky way galaxy likely contains between ten million and a billion stellar-mass black holes, or black holes with masses a few times that of the sun. to date, isolated stellar-mass black holes have not been definitively detected and only two dozen black holes have measured masses ? all in binaries. fundamentally, the study of black holes, both large and small, depends on our ability to make extremely precise measurements of the motions of stars on the plane of the sky. a research group at the university of california-berkeley will improve our ability to make such measurements using adaptive optics (ao) they are developing to remove the blurring of the earth's atmosphere at the w. m. keck observatory telescopes. the investigators will also enhance the training and **\*\*diversity\*\*** of the next generation of astronomical instrumentalists, a historically homogeneous group, through an expansion of the astrotech program to include sessions that bridge between the one-week summer school and external internship programs. the roughly 30 astrotech participants each year will be a diverse cohort with an estimated 75% women or under-represented minority students. the world's largest (> 8 m), ground-based telescopes equipped with ao deliver the best astrometric capabilities for black hole studies. however, current astrometric measurements from ao systems are limited to a relative precision of ~0.1 milli-arcseconds and an absolute precision of ~1 milli-arcseconds. the investigators aim to improve our ability to obtain high-precision

astrometric measurements by a factor of 5x, allowing them to find and weigh large samples of stellar mass black holes both free-floating and in binaries, measure the spin of the supermassive black hole at the galactic center, and improve tests of general relativity in a strong-gravity environment. first, the team will reduce the largest astrometric error term by building and deploying a precision calibration unit to calibrate geometric distortions. second, the team will improve the second dominant error by using state-of-the-art point-spread-function (psf) reconstruction techniques to better model the psf variability in space and time. finally, the team will apply machine learning techniques to telemetry from the ao system, telescope, weather monitors, and atmospheric monitoring stations in order to learn about and optimize system performance, ultimately improving the image quality. the proposed astrometric improvements, needed for black hole studies, will also lay a foundation for new explorations in many other areas of astrophysics. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Amount: \$380,062.00

Abstract: black holes are one of the most exotic phenomena in astrophysics and represent a breakdown in fundamental physics between gravity and quantum mechanics. at the center of our galaxy, a supermassive black hole was discovered thanks to high-precision astrometric observations from the world's largest telescopes ? a discovery awarded the nobel prize in 2020. in addition to the central black hole, the milky way galaxy likely contains between ten million and a billion stellar-mass black holes, or black holes with masses a few times that of the sun. to date, isolated stellar-mass black holes have not been definitively detected and only two dozen black holes have measured masses ? all in binaries. fundamentally, the study of black holes, both large and small, depends on

our ability to make extremely precise measurements of the motions of stars on the plane of the sky. a research group at the university of california-berkeley will improve our ability to make such measurements using adaptive optics (ao) they are developing to remove the blurring of the earth's atmosphere at the w. m. keck observatory telescopes. the investigators will also enhance the training and **\*\*diversity\*\*** of the next generation of astronomical instrumentalists, a historically homogeneous group, through an expansion of the astrotech program to include sessions that bridge between the one-week summer school and external internship programs. the roughly 30 astrotech participants each year will be a diverse cohort with an estimated 75% women or under-represented minority students. the world's largest ( $> 8$  m), ground-based telescopes equipped with ao deliver the best astrometric capabilities for black hole studies. however, current astrometric measurements from ao systems are limited to a relative precision of  $\sim 0.1$  milli-arcseconds and an absolute precision of  $\sim 1$  milli-arcseconds. the investigators aim to improve our ability to obtain high-precision astrometric measurements by a factor of 5x, allowing them to find and weigh large samples of stellar mass black holes both free-floating and in binaries, measure the spin of the supermassive black hole at the galactic center, and improve tests of general relativity in a strong-gravity environment. first, the team will reduce the largest astrometric error term by building and deploying a precision calibration unit to calibrate geometric distortions. second, the team will improve the second dominant error by using state-of-the-art point-spread-function (psf) reconstruction techniques to better model the psf variability in space and time. finally, the team will apply machine learning techniques to telemetry from the ao system, telescope, weather monitors, and atmospheric monitoring stations in order to learn about and optimize system performance, ultimately improving the image quality. the proposed astrometric improvements, needed for black hole studies, will also lay a foundation for new explorations in many other areas of astrophysics. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Taming Nonlinear Inverse Problems: Theory and Algorithms

Awardee: Carnegie-Mellon University

Amount: \$379,999.00

Abstract: while modern developments in large-scale sensing and imaging modalities bring great promise in discovering novel scientific phenomena and improving the quality-of-life, making sense of the sensed data in an efficient and accurate manner require transformative designs of scalable and effective optimization methods for solving inverse problems that go beyond classical linear models. there is a significant need to advance the theory, algorithms, and applications of nonlinear inverse problems, where the collected data exhibit a nonlinear relationship with respect to the unknowns being sought after. focused on taming nonlinear inverse problems, this project will be tightly integrated with education, outreach and dissemination activities including mentoring both graduate and undergraduate students with diverse backgrounds, developing courses and monographs on nonlinear inverse problems in data science, and organizing special sessions at suitable conference venues. the intellectual goal of this project is to develop theoretical and algorithmic foundations for solving nonlinear inverse problems, including the design and analysis of efficient algorithms with provable guarantees, characterization of fundamental trade-offs between resources (sample, computational and memory complexities, signal-to-noise ratio, etc.) and performance (statistical error rates, resolution, etc.), and validations on real data whenever applicable. the project seeks to leverage the **diversity** of multiple measurements and the invariance of data representation in the algorithm designs to minimize complexity and improve performance. the tools and techniques developed in this project will lead to further cross fertilization among the fields of signal processing, inverse problems, optimization theory, and machine learning. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Digitization TCN: Collaborative Research: Bringing Asia to digital life: mobilizing underrepresented Asian herbarium collections in the US to propel biodiversity discovery

Awardee: Trustees of Boston University

Amount: \$379,781.00

Abstract: Asia is the largest continent on earth, and includes the world's tallest mountains, lowest landscapes, and habitats ranging from arctic tundra to tropical rainforests and mangroves to deserts. The plants of this region are incredibly diverse in their identities and functions. More than one-third of the world's 350,000 plant species grow in Asia and include tiny alpine cushion plants, medicinal herbs, ancient crops, and some of the planet's tallest rainforest trees. But documentation of this **diversity** remains inaccessible and research about it is difficult because most herbarium specimens of Asian plants have not been digitized. The All Asia Thematic Collections Network (TCN) will mobilize online 15 million specimens of Asian plants currently housed in the US and around the world. The project will especially focus on digitizing specimens from the unique and critically endangered **bio-diversity** hotspots of Southeast Asia and the Himalaya-Hengduan region. These mobilized digital data will accelerate research to conserve endangered plant species and understand the interacting effects of evolution and global environmental change on plant species **diversity**. The project will apply state-of-the-art informatics tools and high-throughput digitization methods to efficiently and affordably digitize an unprecedented number of herbarium collections. This effort will connect and build long-lasting relationships among 25 large and small consortium institutions in the U.S., Europe, and Asia. The focal areas from which specimens will be digitized encompass five **bio-diversity** hotspots that include ~20% of the world's vascular plant flora and historically spanned 3 million km<sup>2</sup> of primary vegetation that now covers less than 300,000 km<sup>2</sup>. Fundamental **bio-diversity** data for these **bio-diversity** hotspots are lacking, along with the necessary baselines required to characterize species' identity, range, and responses to ongoing climatic change. The overall goals of the All Asia TCN are to rapidly digitize herbarium specimens of

asian plants to advance bio\*\*diversity\*\* discovery and provide critical baseline assessments essential for establishing floristic change in the anthropocene. the project will accomplish this by (1) digitizing 3 million asian vascular plant specimens from u.s. herbaria; (2) developing and applying novel informatics tools and high-throughput digitization methods to massively scale herbarium digitization; (3) aggregating and mobilizing the digitized records from the project with those by international partners in china, france, the netherlands, and russia to establish a single online all asia portal of ca. 15 million specimens; and (4) enhancing opportunities for early career learners in science, technology, engineering, and mathematics by stimulating synergies between bio\*\*diversity\*\* and computer scientists who will use design thinking principles to create real-world informatics solutions to bio\*\*diversity\*\* challenges. to stimulate curiosity in plant \*\*diversity\*\* and botanical exploration among the general public, the consortium members will host several asia-themed notes from nature virtual expeditions to facilitate additional specimen digitization by citizen-scientists. digitized specimen data mobilized through this project will be shared and made available through idigbio.org. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Tuning the Frequency Response of Fractional-Order Microsupercapacitors

Awardee: Florida International University

Amount: \$379,215.00

Abstract: electric double-layer capacitors (edlc) are a subset of electrochemical capacitors that can store and deliver electrical energy at dc and relatively far-from-dc frequencies with effective capacitance between that of aluminum electrolytic capacitors and secondary batteries. they are mostly employed in conventional energy storage applications as secondary power source, such as microprocessors and solar batteries. they have also been demonstrated as efficient energy devices

in oscillators and filters circuits, fractional-order controllers, and fractional-order resonators. however, because of the nature and porous structure of their electrodes and the interfacial electrochemistry of their electrodes/electrolyte phase, many fundamental aspects of their performance metrics are still not well understood, and rational design is practically nonexistent. in particular, edlcs exhibit a dissipative, resistive-capacitive behavior when operating away from dc with an impedance angle anywhere between  $-90$  and  $0$  deg. in this project, miniaturized edlcs based on structured 2d and 3d electrode arrays will be designed and fabricated with the objective of understanding and controlling their non-ideal, fractional-order behavior. we will develop and study the effect of doped electrolytes in order to tune the electric-field-induced ionic transport in the presence of physical obstacles. the expected outcome is a general procedure and design rules to apply in order to fine-tune and control the impedance phase shift of edlcs and their energy-power performance. modeling and simulation using mean-field poisson-nernst-plank model will be carried out in order to provide a fundamental understanding of the frequency response of the devices. system-level modeling using fractional-order mathematical tools and equivalent circuit models will also be developed in connection with rc-based circuitry. the controllable fractional-order behavior of the edlcs will be verified and their frequency-domain application will be demonstrated. this project will contribute to the research, education, and **\*\*diversity\*\*** goals of florida international university.

the objectives of this project are to tackle the lack of knowledge on the frequency-domain metrics and performance of factional-order capacitors using both experimental and modeling approaches. we aim to investigate the following: (1) electrode-electrolyte interface specifications and electrolyte parameters that enable the tuning of the electrical characteristics of an edlc over an extended frequency bandwidth; (2) the electro-kinetic effects taking place in the supporting electrolyte of an edlc, and how they affect the frequency-domain metrics of the device; (3) modeling using 3d-circuit interconnects and finite-element methods to understand the overall electric characteristics; and (4) the frequency response of the edlcs and their application in (frequency-domain) filtering and (time-domain) memory applications. this award reflects nsf's statutory mission and has been

deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: OCE-PRF Detecting signatures of multigenerational plasticity in a marine forage fish

Awardee: Woods Hole Oceanographic Institution

Amount: \$378,315.00

Abstract: this award is funded in whole or in part under the american rescue plan act of 2021 (public law 117-2). coastal marine ecosystems face multiple anthropogenic stressors including increasingly severe events of co-occurring acidification and hypoxia. these periodic but acute environmental stressors can directly impact the abundance, **\*\*diversity\*\***, and commercial value of coastal fish stocks. rapid acclimation of key physiological processes can provide short-term protection against extreme conditions. importantly, these phenotypic modifications can be passed on to subsequent generations thereby priming offspring for increased tolerance. however, for most

fish species the scope for phenotypic plasticity and the precise mechanisms of action are poorly understood. this severely limits our ability to anticipate responses in the majority of ecologically and economically important marine species. the overarching objective of this proposal is to investigate the potential for within-generational and multigenerational plasticity in response to co-occurring hypoxia and acidification in the forage fish atlantic silverside (*menidia menidia*). the atlantic silverside is a foundational species and an essential trophic component of coastal food webs along the north american atlantic coast and serves as key prey item for many seabirds and commercially important fish. understanding the long-term bioenergetic impacts and the potential for rapid adaptation in this species will therefore fundamentally advance our understanding of the ecological consequences of rapid environmental change in coastal marine ecosystems. the project will be centered around a series of laboratory exposure experiments and state-of-the-art metabolic assays utilizing wild-caught atlantic silversides collected during their spring spawning season. the pi will investigate how parental environments influence offspring phenotype by conditioning mature wild atlantic silversides (f0) to contrasting fluctuating co<sub>2</sub>/o<sub>2</sub> treatments. the f1 generation will be then reared in a reciprocal transplant experiment to quantify how parental and offspring treatment levels affect key life-history traits including survival, growth, and aerobic performance. surviving f1 offspring will be reared until maturity to evaluate how environmental stress experienced during early development affects adult reproductive capacity. furthermore, the pi will investigate the role of biological memory in multigenerational plasticity by exposing f2 offspring to factorial combinations of grandparental and parental environments. in parallel, the pi will investigate how molecular mechanisms may mediate rapid adaptation to changing environments using transcriptomics (rnaseq) and genome-wide dna methylation profiling (methylseq). linking molecular changes with whole organism phenotypic responses will broaden our understanding of the effects of multiple stressors on an ecologically important species which will provide clues for developing mitigation plans to protect coastal food webs from various climatic factors. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's

intellectual merit and broader impacts review criteria.

Title: REU Site: Geosciences Program in Energy and Environmental Resource Sustainability (GeoPEERS)

Awardee: Pennsylvania State Univ University Park

Amount: \$377,035.00

Abstract: this award is funded in whole or in part under the american rescue plan act of 2021 (public law 117-2). the goal of the geosciences program in energy and environmental resource sustainability (geopeers) reu is to train the next generation geoscience workforce for industry and academia. while oil and gas jobs will likely continue to decline slowly over the next several decades, the industry will remain, and we must train geoscientists who can skillfully, ethically, and strategically locate and extract these resources. at the same time, demand for resources such as clean water, fertile soil, and renewable energy is increasing. diversification of the global energy and resource portfolio is already underway, and new skill sets will be required of geoscientists entering academia and the workforce. the geopeers reu program will train participants holistically to approach the industry of resource extraction and energy production from a sustainability perspective. the field of geosciences is also reckoning with a profound lack of **\*\*diversity\*\*** in its workforce. we will advertise broadly and draw upon existing partnerships with minority-serving institutions in order to find highly qualified applicants from a diverse range of backgrounds. because simply recruiting a diverse cohort is not enough, we will strive to intentionally and explicitly create a supportive, inclusive, and equitable educational environment. by incorporating new skills sets and perspectives into our training program, and by intentionally building a diverse and inclusive participant community, geopeers will prepare a new generation for the geosciences of the future. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: MCA: Genomic diversification and speciation along ecological gradients in a marine fish radiation

Awardee: California State L A University Auxiliary Services Inc.

Amount: \$373,704.00

Abstract: understanding the formation of new species in the marine environment has proven to be a challenging task for evolutionary biologists. the potential for high levels of migration and the apparent lack of geographical barriers create a scenario where ecological diversification and life history shifts are likely important in the speciation process. this research program will determine the genomic basis of divergence among closely related species and populations along latitudinal and depth gradients to determine the role of adaptation in the speciation process. rockfish (sebastes) are an ideal system to examine these questions as they are a diverse group of temperate fishes inhabiting a wide array of habitats, and they have been subject to numerous phylogenetic studies. this study will build upon a growing set of studies aimed at better understanding the speciation process in the marine environment. training opportunities will be provided to undergraduate and graduate students at cal state la, and data from this project will also serve as a resource for the management of rockfish, many of which are commercially important. this project will utilize genome scans and de novo genome assemblies to test for speciation histories of rockfish associated with divergence along ecological (depth) or geographic (latitude) gradients. these findings can be used to better understand the role of natural selection on the genome and how this contributes to the diversification of this group. the first aspect of the study will examine the role that ecological adaptation along a depth gradient has played in the formation of new species. the second aspect will contrast these findings with latitudinal divergence among closely related species. together these results will provide novel insights into the speciation history and genomic divergence for closely related marine species, and provide a framework for understanding the relative roles of

selection and genetic drift on generating and maintaining marine **\*\*diversity\*\***. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Engineering All-Solid Metal-Sulfur Batteries: Transport, Speciation, and Kinetics in Sulfur Copolymer Composite Cathodes

Awardee: University of Notre Dame

Amount: \$371,439.00

Abstract: metal-sulfur rechargeable batteries are a potentially cost-effective solution for replacement of li-ion batteries for use in electric transportation. the energy density of lithium-sulfur and magnesium-sulfur batteries can exceed that of li-ion, but only at low electrolyte-to-sulfur ratios. however, it is difficult to engineer sulfur batteries for high performance with low levels of liquid electrolyte. in addition, elimination of volatile battery components to improve safety is preferred. in this project, the investigator will investigate solid-state metal-sulfur batteries based on copolymerized sulfur cathodes. the influence of the chemistry and morphology of the sulfur copolymer cathode on the ion transport, sulfur speciation, and reaction rates will be investigated. the use of a solid copolymer interlayer to prevent the dissolution of sulfur species into the bulk polymer electrolyte will also be explored. this research will engage graduate and undergraduate notre dame students and visiting undergraduates from the xavier university of louisiana to promote the training and retention of researchers in the field of electrochemical engineering. additionally, the number, **\*\*diversity\*\***, and training of the next generation of researchers in the chemical sciences and engineering will be enhanced by development of afterschool enrichment programming. this fundamental engineering science research will be transformative for its contributions to the understanding of the effects of local environment on sulfur and poly(sulfide) electrochemical properties in the solid-state. copolymerization of elemental sulfur and organic monomers will be

leveraged to facilitate tune the sulfur cathode environment, including the size and morphology of sulfur-rich and ion-rich domains, the interactions of ion-solvating components with poly(sulfide)s, and charge-transfer kinetics. spectroelectrochemical techniques will be used to investigate sulfur/(poly)sulfide speciation and reaction pathways. separately, copolymer interlayers for active cation transport and polysulfide rejection in the solid-state will be investigated. ion transport in both the cathode and interlayer nanostructured solid-state environments will be probed. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: The Merian Survey. Characterizing Dark Matter and Feedback in Star Forming Dwarf Galaxies

Awardee: Princeton University

Amount: \$370,793.00

Abstract: while most of the mass in the universe is unseen, the smallest galaxies in the universe (the so-called dwarf galaxies) pose significant challenges to this ?dark matter? model. in order to further test our best dark matter models, a large observational survey of dwarf galaxies is needed. this project focuses on the meriam survey, which will observe 100,000 dwarf galaxies with known

distances. furthermore, each of the dwarf galaxies in this survey has constraints on their dark matter content from other methods. the new data will provide their stellar structure and colors. these results can all be taken together to test our ideas of dark matter in the universe. the team will place priority on recruiting a diverse group of students who will carry out the data mining that will be required in the era of the vera rubin observatory. established programs at both princeton and uc santa cruz recruit historically underserved students for summer research and then continuing cohort support. these students will be trained in "big-data" and modern science analysis with merian. extensive studies of dwarf galaxies have revealed a considerable scatter in many of their fundamental properties. in particular, galaxies with stellar mass of  $10^8 - 10^9$  msun present a **\*\*diversity\*\*** of star formation rates and rotation-curve shapes which are in tension with theoretical models. reliably characterizing the dark matter distribution and baryonic processes in these galaxies, such as feedback, is key to in order to establish a complete picture of dark matter on small scales. the merian survey will obtain a volume-limited census of dwarf galaxies in this mass range at  $z=0.058-0.1$ . using two custom made filters, merian will provide redshifts to a complete sample of 100,000 star forming dwarf galaxies (two orders of magnitude larger than sdss+gama) over an area of 870 deg<sup>2</sup>. combined with deep+high spatial resolution imaging from the hyper-suprime camera, this program will result in high s/n weak lensing profile measurements for dwarf galaxies, probing their dark matter halos out to their virial radii. also, hyper-suprime camera imaging will be used to measure dwarf sizes and shapes. the next generation of scientists must be trained to deal with the deluge of vera rubin observatory data coming in the next decade. programs at both princeton and uc santa cruz recruit historically underserved students for summer research and then continuing cohort support. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: ISS: Collaborative Research: Individual and Collective Behavior of Active Colloids in Microgravity

Awardee: Florida International University

Amount: \$367,549.00

Abstract: this nsf-casis project involves microgravity experiments on the international space station (iss), complementary terrestrial experiments and theoretical/numerical modeling to improve understanding of active colloid transport. active colloids move by extracting energy from their surroundings and transforming it into mechanical work. these materials have similarities with biological matter, especially for concentrated suspensions where particle-particle interactions yield collective behaviors similar to those found in nature such as swarming flocks of birds, schools of fish and bacterial colonies. although most theoretical models pertain to an isolated particle traveling in the bulk, the weight of active colloids on earth causes them to settle at the bottom of the experimental chamber where they translate parallel to the surface. long term microgravity conditions on the iss offer a unique opportunity to mitigate buoyancy and sedimentation and obtain bulk measurements that can be compared with theoretical models and elucidate the role of particle-wall interactions, which complicate terrestrial experiments. the results of this project may transform a variety of applications in biomedicine and applications at the food-water-energy nexus including colloidal assembly and bubble/droplet transport. the project is a collaboration between colorado mesa university (cmu) - a primary undergraduate institution with a diverse student body ? and florida international university (fiu) - a research intensive minority serving institution (msi). it offers a unique opportunity to promote **diversity** through exposure of undergraduate students to timely research and industry collaboration with the implementation partner space tango. the research team will develop a module for fiu's ?engineers on wheels? program, which visits local schools, and will collaborate with the eureka science museum and maverick innovation center in colorado. this nsf-casis project will provide a comprehensive understanding of complex physical mechanisms controlling the mobility of individual active colloids and their collective behavior with two distinct goals: (1) optimizing active colloid transport, and (2) understanding effects of microgravity on collective dynamics and non-equilibrium interactions of active matter. the absence of buoyancy in

microgravity is expected to resolve a conundrum in terrestrial experiments wherein theoretical models of these systems are derived for isolated particles in the bulk while experimental measurements are almost always made near a wall owing to gravity-induced sedimentation. proximity to a wall and the accompanying particle-wall interactions (hydrodynamic, phoretic, electrostatic etc.) are often invoked as corrections to explain discrepancies between theory and experiment. however, the precise roles of particle-wall interactions cannot be isolated without comparable measurements far from the wall. sustained microgravity conditions will enable measurement of particle mobility in the bulk, providing an experimental reference for theoretical models and insight into competing buoyancy effects and wall-particle interactions. comparison of particle-particle interactions on earth and on the iss will also elucidate effects of microgravity on collective behavior in active matter and dense colloidal systems including 3d phase separation. microgravity experiments will be complemented with terrestrial bulk measurements using optical tweezers as an external forcing mechanism, which will provide insight into other active colloid transport mechanisms (e.g., catalytic) and the applicability of such external forcing for future fundamental studies. the collaboration between fiu and cmu and the partnership with space tango offers a unique opportunity to engage students. undergraduate students will participate through capstone projects at fiu, while cmu students will travel to fiu and gain exposure to a research intensive institution. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Unusual Concentration Phenomena in Probability, Analysis, and Geometry

Awardee: Princeton University

Amount: \$364,540.00

Abstract: many complex systems behave in a random fashion at the smallest scales. why then does

the world around us appear to be so predictable? this is explained in a very general context by a principle known as concentration of measure: smooth functions of many independent random variables behave in an essentially predictable manner. precise mathematical formulations of this phenomenon provide powerful tools for studying complex random structures. this project aims to study new concentration phenomena that arise from unexpected connections with several different areas of mathematics: from the study of embeddings (how well can data be represented in a particular space?); from the study of exotic shapes which date back to old problems in geometry from over a century ago; and from the study of non homogeneous random matrices, which are widely used in modern data science. the unusual features of these problems motivate the development of the theory in new directions, as well as the introduction of new tools that may be applied to a wide range of random structures that arise in both pure and applied mathematics. the project includes educational, mentoring and outreach activities that are aimed at attracting and training the next generation of mathematicians, and at increasing participation and **\*\*diversity\*\*** in the mathematical sciences. it also provides research training opportunities for graduate students.

the aim of this project is to systematically develop novel concentration phenomena that arise from problems in probability, functional analysis, metric geometry, and convex geometry. the project is organized around three topics. the first topic aims to develop a general theory of concentration inequalities for functions taking values in normed spaces. the second topic aims to understand certain long-standing questions in convex geometry that may be viewed as unusual analogues of the concentration phenomenon. the third topic is concerned with concentration inequalities for the norms of non-homogeneous random matrices. the investigation of concentration phenomena in nonstandard settings motivates new questions and the development of new tools that are both of direct probabilistic significance, and that provide new perspectives on problems in other areas of mathematics. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Awardee: University of Montana

Amount: \$364,234.00

Abstract: the greenland ice sheet has experienced devastating melt in recent years. recent scientific reports highlight how vulnerable the greenland ice sheet is to arctic climate change and draw a dire picture of the impact of sea-level rise. in order to equip society with the best forecasts of sea level rise for planning, scientists need to improve the ability to simulate ? or model ? the response of ice sheets to climate change. for this project, scientists from different branches of ice-sheet research will work together to improve ice sheet modelling. the researchers will leverage recent scientific advances to model the entire greenland ice sheet in order to investigate long-term ice-sheet sensitivity to changes taking places in the ocean and atmosphere. the research group is committed to creating an inclusive environment where all team members can learn and excel. the team contains **\*\*diversity\*\*** in ethnicity, gender and rank, and will train six early career scholars, recruiting specifically from groups underrepresented in the geosciences, which is among the least diverse stem fields in the u.s. results will be made publicly available and will facilitate a broad range of future research about the arctic system, including ice sheet modeling, model spin-up, paleoclimate reconstruction/synthesis and glacier history. to elevate the capacity of outreach and education programs developed during their first project, the team will build on their ?scientists are superheroes? outreach program and leverage other, existing outreach frameworks, including making connections with greenlandic communities and with high school student intern programs at their universities linked to the young women?s leadership school (bronx, ny) and the spring valley (ny) branch of the naacp, coordinated by our dedicated project educator and outreach specialist. reducing uncertainties in ice-sheet model predictions is crucial in society?s handling of the sea level crisis. uncertainties related to ice-sheet instability arise from limited observations, inadequate model

representation of ice-sheet processes, and limited understanding of the complex interactions between the atmosphere, ocean, and ice sheets. how atmospheric and oceanic forcing vary through time, and at what timescales each are capable of forcing rapid change, are critical for predicting future ice mass loss, but scientists have been observing ice sheet change for only a short period of time (decades). the pis propose to scrutinize greenland ice sheet change spanning from the beginning of the holocene (12,000 years ago) to 2100 ce, making it possible to evaluate the varying roles of atmospheric and ocean forcing on decadal-to-centennial timescales relevant for the future greenland ice sheet evolution. the pis will utilize their established multi-disciplinary collaboration to combine ice sheet modelling, climate forcing and reconstructions of past ice-sheet change. this will position the team to make predictions of future ice sheet change that are grounded in greenland ice sheet behavior during past climate swings that occurred prior to our brief window of modern observation. the work will lead to lasting products to serve the community's collective effort to better understand ice sheet change: 1) a state-of-the-art ice-sheet model optimized for simulations over long timescales, 2) a holocene-through-modern set of atmospheric and ocean state estimates optimized for forcing an ice-sheet model, and 3) a database of past-ice sheet configurations and paleoclimate records formatted for model-data comparison. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Targeted Infusion Project: Increasing Mathematics Achievement Gains by Engaging Students of STEM at Tennessee State University

Awardee: Tennessee State University

Amount: \$363,788.00

Abstract: the historically black colleges and universities undergraduate program (hbcu-up), through targeted infusion projects, supports the development, implementation, and study of evidence-based

innovative models and approaches for improving the preparation and success of hbcu undergraduate students so that they may pursue stem graduate programs and/or careers. accordingly, tennessee state university will establish its ?increasing mathematics achievement gains by engaging students (images)? project that will support the enhancement of introductory mathematics courses to the benefit of undergraduate students who will pursue degrees in science, engineering, technology, and mathematics (stem). the images project is designed to provide a pathway for on-time graduation, to increase student learning and engagement, and to promote academic and professional development for stem students. this project will target first year students who are majoring in mathematical sciences, architectural engineering, civil engineering, electrical engineering, or mechanical engineering and who do not meet the act requirement for enrolling in calculus i during their first semester at tennessee state university. the project comprises of three major components: the redesign of a one-semester pre-calculus course, the implementation of adaptive and active learning strategies, and the provision of student support services. the first-year mathematics experience will include pre-calculus i with adaptive learning strategies during the fall semester, calculus i with active learning strategies during the spring semester, and calculus ii during the summer term with active learning strategies in an online format. the student support services will include peer tutoring, peer mentoring, a stem student seminar series, and opportunities for experiential learning. the images project will enhance the academic infrastructure of existing stem disciplines at tennessee state university and contribute to strengthening \*\*diversity\*\* in stem career fields. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Proposal: NSF-DFG Echem: Understanding the Mechanism of Urea Oxidation on Nickel-Based Electrocatalysts

Awardee: Oregon State University

Amount: \$362,348.00

Abstract: urea is a common high-nitrogen chemical waste product of mammalian metabolism, and a major component of fertilizer. It poses significant threat to water resources from agricultural run-off and municipal wastewater. A promising means for removing excess urea is to oxidize it electrochemically to produce harmless compounds. Urea removal processes can also be used to generate electricity and to produce hydrogen for fuel cells. Electrochemical urea removal therefore exhibits strong potential as a transformative technology by converting a harmful waste product to the benefit of society, industry, and the environment. The project brings together researchers from the United States and Germany to apply a synergistic blend of experimental and theoretical methods to the study of electrochemical urea removal from water. In particular, the project seeks fundamental understanding of catalytic urea oxidation that is needed to develop feasible urea removal technologies. Effective urea removal systems are key to a large number of technological applications including municipal and agricultural wastewater treatment, remediation of fertilizer run-off, ammonia synthesis, hydrogen production, and electricity generation. Other benefits from this project will include workforce development and educational outreach to underrepresented grade-school students. These efforts will promote increased diversity in STEM fields, a student exchange program between Germany and the US, and improved scientific literacy of the general public. The goal of this research project is to develop comprehensive knowledge of electrochemical urea removal over nickel-based catalysts, based on experimental and theoretical research spanning molecular and device levels. Electrochemical urea removal will be studied by density functional theory calculations, vibrationally and electronically resonant sum frequency spectroscopy, and electrochemical measurements of reaction rate and product distributions. Particular attention will be paid to the active form of the nickel oxide electrode as it exists in different phases and oxidation states depending on electrode potential and history, such as aging and preparation method. This combined electrochemical, spectroscopic, and computational approach provides insight related to catalyst structural changes and how they affect the urea reaction mechanism, reactivity, and

effectiveness of nickel, nickel-iron, and nickel-chromium catalysts. the outcomes of this research will greatly advance the scientific understanding of electrochemical urea removal -- about which little is known -- and establish a foundation in the wider field of electrocatalysis regarding electrochemical reactions on oxide surfaces and on surfaces that undergo a change in oxidation state as part of the overall reaction mechanism. successful completion of this research will benefit society through sustainable methods for treating wastewater and agricultural run-off that will reduce demand on water supply systems and enhance the bio\*\*diversity\*\* of marine ecosystems. this project was awarded through the "nsf-dfg lead agency activity in electrosynthesis and electrocatalysis (nsf-dfg echem)" opportunity, a collaborative solicitation that involves the national science foundation and deutsche forschungsgemeinschaft (dfg). this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: HSI ATE Hub 2: Professional Development for Culturally Responsive Technician Education

Awardee: Arizona State University

Amount: \$361,307.00

Abstract: this project aims to better serve and support a diverse population of students who are pursuing credentials in skilled technical fields. to do so, the project will guide faculty to adapt and implement culturally responsive instruction in technician education courses. the project is designed to increase the retention of hispanic students in stem career pathways, particularly in advanced-technology fields. the project builds on the hispanic serving community college kickstarter project, the hispanic serving institutions hsi/ate hub project, and the westchester community college photonics and laser project. the project team will develop, pilot test, and disseminate a faculty professional development model that can help to shift faculty understanding, practice, and mindset

from emphasis on perceived student deficits to asset-based thinking and mutual respect. the professional development will be organized into three tiers. tier 1 is designed to establish awareness and support first steps. tier 2 will focus on the development, implementation, and testing of culturally responsive instruction practices in technician education. tier 3 will focus on creating a community of instructors and emerging leaders that engages in practice, theory building, and applied research into effective educational practices. the overall project goal is to develop faculty knowledge, skills, values, attitudes, and mindset so that more hispanic students will complete advanced technology programs. in doing so, the project can increase the **\*\*diversity\*\*** of the technician workforce and help to mitigate disproportionate impacts of covid-19 on hispanic communities. this collaboration includes faculty and administrators in technician education programs, higher education researchers, experts in culturally responsive instruction, and industry partners to further conceptualize, operationalize, and test the validity of culturally responsive instruction in the skilled technical fields of applied engineering and applied computing and cyber-security. additionally, the project will test the hypothesis that micro-credentials are valuable for incentivizing faculty participation in project activities and that micro-credentials will be recognized by educational and industry stakeholders as valuable evidence of expertise and experience. the mixed method evaluation is process -oriented to facilitate development of a model and outcomes-oriented to assess faculty and student outcomes that includes assessment of changes in knowledge/awareness, skills/behavior, and attitudes/mindset. this project is funded by the advanced technological education program that focuses on the education of technicians for the advanced-technology fields that drive the nation's economy. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: REU Site: Collaborative Research: Research Opportunities in Rock Deformation

Awardee: Washington University

Amount: \$359,067.00

Abstract: rock deformation, a sub-discipline of earth science, uses geology and engineering methods to measure the strength of rocks. information about rock strength can be applied to a wide range of problems in engineering, natural hazards, and material science, as well as geology. however, very few scientists specialize in the field of rock deformation; thus, many important research questions remain unexplored or underexplored, slowing advances in science and engineering. geoscience departments at primarily undergraduate or primarily minority-serving institutions often do not have active rock deformation research programs and labs that deal with rock deformation are relatively rare. this reu site aims to increase access and exposure of a diverse population of students to career opportunities in this area. the project offers undergraduate students the unique opportunity to conduct summer research at one of eleven state-of-the-art, experimental rock deformation labs across the country. experts in rock deformation will serve as mentors to a cohort of 10 students each summer. this reu site provides access and training, professional and career development activities, and robust workforce development for students from all backgrounds.

the reu site will provide research and mentorship opportunities for undergraduate students in the field of experimental rock deformation. the long-term objective is to increase the number and **\*\*diversity\*\*** of students pursuing research or industry careers in rock deformation. student participants will receive training in research methods and professional development topics that will provide a stable foundation for graduate school or related career paths. a large team of pIs and senior participants ensures that students who participate in the program will have a deep professional network to support their future endeavors. students will be drawn from the full spectrum of higher education institutions. strong emphases will be placed on recruiting students from diverse and under-represented backgrounds, and smaller colleges and universities that do not have research programs in rock deformation. the reu site will include three integrated sessions: a field session to introduce students to the geological study of deformed rocks, a laboratory session where

students conduct experiments on specimens collected during the field session, and a conference session where students can present the results of their research projects. the reu site will adopt a distributed model, leveraging the combined lab capacity of the pis and other senior participants to support 10 students per year. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Leveraging the Power of Reflection and Visual Representation in Middle-Schoolers' Learning During and After an Informal Science Experience

Awardee: Loyola University of Chicago

Amount: \$358,229.00

Abstract: this project addresses a longstanding problem in informal science education: how to increase the likelihood of consequential science, technology, engineering, and mathematics (stem) learning from short duration experiences such as field trips. although informal learning experiences can greatly contribute to interest in and knowledge of science, there is a shared concern among educators and researchers that students may have difficulty recalling and using scientific information and practices emphasized during these experiences, even though doing so would further their science learning. nonetheless, science learning is rarely, if ever, a "one-shot deal." children acquire knowledge about science cumulatively across different contexts and activities. therefore, it is important that informal science learning institutions identify effective practices that support the consolidation of learning and memory from exhibit experiences to foster portable, usable knowledge across contexts, such as from informal science learning institutions, to classrooms, and homes. to this end, this research in service to practice project seeks to harness the power and potential of visual representations (e.g., graphs, drawings, charts, maps, etc.) for enhancing learning and encouraging effective reflection during and after science learning experiences. the project promises

to increase learning for the 9,000+ 5th and 6th grade students from across the rurality and growing **\*\*diversity\*\*** of the state of maine who annually participate in labventure, a 2.5-hour exploration of the gulf of maine ecosystem at gulf of maine research institute. the research will provide new and actionable informal science learning practices that promote engagement with visual representations and reflection, and science understandings that can be applied broadly by informal science institutions. this project is funded by the advancing informal stem learning (aisl) and the discovery research prek-12 (drk-12) programs. it supports the aisl program goals to advance new approaches to, and evidence-based understanding of, the design and development of stem learning in informal environments. it supports the drk-12 program goal of enhancing the learning and teaching of stem by prek-12 students and teachers. the project is grounded in the idea that visual representations, including drawings, can both enhance science learning and encourage reflection on doing science that can support extension of that learning beyond a singular informal science experience. the project uses design-based research to address the following research questions: (1) does reflection during an informal science learning experience promote students' retention and subsequent use of science information and practices that are part of the experience? (2) does interpreting and constructing visual representations, such as drawings, improve students' understanding and retention of information, and if so, how and when? and (3) does combining visual representations and narrative reflections confer benefits on students' science learning and engagement in science practices both during the informal learning experience, and later in their classrooms and at home? these questions will be pursued in collaboration with practitioners (both informal educators and classroom teachers) and a diverse team of graduate and undergraduate student researchers. approximately 600 student groups (roughly 3000 individual students) will be observed during the labventure experience, with further data collection involving a portion of these students at school and at home. the project will yield resources and video demonstrations of field-tested, empirically based practices that promote engagement with visual representations and reflection, and science understandings that can travel within students' learning ecosystem. in support of broadening

participation, the undergraduate/graduate student researchers will gain wide understanding and experience connecting research to practice and communicating science to academic and nonacademic audiences. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Developing a Seismic Model for Investigating Layering in Cratonic Lithosphere beneath Africa

Awardee: University of Rochester

Amount: \$357,817.00

Abstract: this award is funded in whole or in part under the american rescue plan act of 2021 (public law 117-2). the lithosphere is the stiff outer shell of our planet - it is the rigid plate of plate tectonics. in the oldest and most stable regions of continents (cratons) the lithosphere is expected to be cold and thick, yet we observe a wide-spread, near-constant layer internal to the lithosphere, almost akin to the crust-mantle boundary, but expressed as a velocity reduction. this puzzling and ubiquitous observation of 'mid-lithospheric layering' has resulted in different, sometimes contradictory, explanations (i.e., partial melt, anisotropy, chemical stratification, or short-term rheological weakening). in this study, the investigators will develop a new seismic model of the lithosphere useful for testing proposed models of lithospheric layering beneath africa. the multi-decadal investment in the innovative africaarray initiative, the **\*\*diversity\*\*** of cratons, and a growing number of permanent and temporary seismic networks on the continent, with publicly available data, has opened a new vista on our ability to resolve fine-scale lithospheric layering on the continent. similarly, new passive-source imaging using spectral coherence of ambient noise, machine learning, and probabilistic analysis of converted body waves is poised to ensure maximum utility from the archived seismic datasets. this project will engage early career scientists, train minority ph.d. students, and promote education and outreach goals for recruiting under-represented

undergraduate students by designing new courses that expose students to the optimal use and management of high-performance computing resources. the project will address gaps in current efforts to study lithospheric layering on the continent. the investigators will conduct analysis of all publicly available seismic data on the continent, with sensitivity to the crust and upper mantle lithosphere, and prepare and publishing measurements of: (1) group and phase velocity of broad-band ambient noise and earthquake records for love and rayleigh surface waves, (2) depth and sharpness of compressional and shear body wave reflectivity of lithospheric discontinuities, (3) quantify uncertainty in phase velocity maps and, (4) provide an updated continent-wide reference model of the african crust and upper mantle (lithoaf+), using a probabilistic joint inverse approach to reporting uncertainty in each stage of measurement and model-construction (i.e., 1-4). the expected peer-reviewed studies, when interpreted with complementary experimental and geophysical constraints (i.e, conductivity and mineral physics), will advance our understanding of cratonic lithospheric layering and the geological evolution of continents. integrated modeling, using other geophysical constraints, will also advance the understanding of (1) the origin of the elevated african topography, (2) the origin of orphan tremors, intra-plate earthquakes, and volcanism, and their connection to the well-known african superplume, (3) the broad-scale evolution of continental rifting and formation of new ocean basins, and (4) multi-stage assembly and break up of gondwanaland. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Examining the Geography of Pathogen Spillover

Awardee: Virginia Polytechnic Institute and State University

Amount: \$357,749.00

Abstract: this project examines disease spillover, which refers to the transmission of parasites and pathogens from one species to another. the transmission of parasites and pathogens between

species is a source of infectious diseases that impact human populations, including past examples such as ebola, sars, and covid-19. as a complement to theoretical models, this study focuses on the pathways that lead to spillover of rabies among populations of bats. the transmission of rabies among bats is relatively common, which enables tests of predicted spillover dynamics. the study includes sampling of bat populations in multiple locations to determine the prevalence of rabies, which potentially varies in response to multiple factors, including the genetic **diversity** of the respective populations. the researchers also draw on archival data to assess the probability of spillover events in relation to landscape disturbancethe project provides training opportunities for students, and the results will be shared with diverse institutions that monitor public health and wildlife populations. this study contributes to understandings of the risks of disease spillover between species, including humans. the research focuses on bat-borne rabies transmission, which occurs relatively frequently, permitting insights of transmission pathways that could similarly characterize other infectious pathogens. to assess the determinants of rabies transmission, the researchers use multiple methods. blood samples collected from bats at diverse locations permit laboratory work to assess the extent of rabies infections in relation to the genetic **diversity** of the populations and ecological variables. the researchers also use archival records on rabies infections to assess the predictors of spillover events, such as landscape disturbance and the expectation that spillover is relatively more common near the center of the bats? ecological niche. the study includes the development of theoretical models that reflect the inferred dynamics of spillover events over time, and these models could be applied to studies of similar pathogens. the findings inform diverse efforts to mitigate the risks of spillover events for human populations. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: MRI: Acquisition of a fluorescence activated cell sorter (FACS) supporting multi-disciplinary

approaches to exploring biological responses

Awardee: Rhodes College

Amount: \$357,741.00

Abstract: an award is made to rhodes college to support the acquisition of a fluorescence activated cell sorter (facs) to enhance the research of faculty and training of undergraduate students at rhodes college and institutions in the memphis area. this instrument allows separation of small particles, including living cells, from large populations and is based on very specific features such as particle size or the presence of a protein. as cells are isolated, very detailed information can be gathered about each cell and the living cells can be further studied. addition of the facs instrument will transform the ability to train the next generation of scientists in rhodes faculty-led coursework, mentored research, and outreach programs at this research-active primarily undergraduate institution (pui). this instrument allows fast and precise analysis and separation that is very robust so that it will help scientists and undergraduate students answer a broad range of biological questions, including the how genes function, how cells respond to stress, and questions regarding bio\*\*diversity\*\* in ecological systems. projects will focus on (1) epigenetic gene regulation; (2) parental control of gene expression; (3) response to viral infection; (4) metal intake in a type of salmonella bacterium; (5) immune system response to a type of fungal pathogen; (6) vitamin dependent cell cycle progression; (7) phytoplankton communities in freshwater ecosystems; and (8) speciation response to changes in ploidy. this work will be shared with the scientific community through presentations at national conferences and publication with undergraduate co-authors in peer-reviewed journals. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: American Meteorological Society Summer Policy Colloquium 2021-2023; Washington, DC

Awardee: American Meteorological Society

Amount: \$356,100.00

Abstract: this award supports participation of students and early-career scientists in the summer policy colloquium of the american meteorological society. the summer policy colloquium addresses the need for interaction between policy makers and researchers who have domain expertise in areas relevant to policy decisions. it provides an opportunity for researchers interested in decision support to interact with policy makers and learn about policy making. each year the colloquium brings 20 to 40 participants to washington dc for two weeks of intensive interactions with scientist-leaders from the legislative and executive branches, executives from ngos, policy analysts, science journalists, and other stakeholders working in the policy arena. in addition to in-person dialog and interaction colloquium participants are given pre-assigned reading and work through group exercises and case studies to learn about the policy making process. funds provided through this award support the participation of 15 graduate students and early-career scientists in the colloquium. nsf-funded participants are selected through a competitive process, based on the applicant's potential and accomplishments and taking into account **\*\*diversity\*\***, equity and inclusion.

the primary broader impact of the award is the development of a cohort of researchers in disciplines related to weather and climate who can provide decision support for policy decisions in these areas. such decision support is increasingly valuable as stakeholders and decision makers at all levels of government face a growing variety of challenges related to the management of weather and climate risk. many researchers are interested in providing decision support, but the education and experience of scientists does not adequately prepare them to perform this role. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: An Evidence-Based Approach Towards Technology Workforce

## Expansion by Increasing Female Participation in STEM Entrepreneurship

Awardee: University of Maryland, College Park

Amount: \$351,259.00

Abstract: this is a collaborative project, with the university of wisconsin-madison as the lead institution and the university of maryland as the partnering institution, to explore the entrepreneurial proclivity of undergraduate women majoring in stem fields. the researchers propose a multi-method approach led by an interdisciplinary team to (1) identify factors that influence entrepreneurial proclivity and (2) develop and test interventions related to closing gender disparities in stem entrepreneurship. the research includes the analysis of a comprehensive administrative database to identify mechanisms for potential interventions and field experiments to achieve greater gender parity in entrepreneurial career choices for stem students. results of the field experiments will be integrated with the database to produce outcome measures. the project will produce empirical evidence to increase the understanding of student entrepreneurship and inform interventions that improve entrepreneurship participation for women in stem. the researchers will frame the research design and methods using the individual-opportunity nexus theory that knowledge is a precursor to entrepreneurship. there are four hypotheses: (1) greater entrepreneurial proclivity will be found in women in stem fields with higher curriculum **\*\*diversity\*\***, who have taken at least one business class, who are enrolled in stem courses with students with higher **\*\*diversity\*\*** in their courses, and who are enrolled in stem courses with students who have taken one or more business classes. (2) women stem students demonstrate higher entrepreneurial proclivity when they are exposed to relatable role models in entrepreneurship. (3) women stem students demonstrate higher entrepreneurial proclivity when entrepreneurship is presented as a gender-neutral field. (4) women stem students demonstrate higher entrepreneurial proclivity when they are exposed to entrepreneurial success stories. the researchers will make causal inferences about factors that influence entrepreneurial proclivity of women in stem by measuring self-reported activities, analyzing administrative data, and documenting student start-ups. the core of the project is based on data

drawn from a data infrastructure that combines administrative data with results of an annual survey. the researchers will use those data to evaluate the mechanisms that influence the underrepresentation of women in entrepreneurship. they will augment the data infrastructure with a field experiment to test hypotheses informed by existing literature and findings from their data analysis. this project is co-supported by the ehr core research program that funds fundamental research on stem learning and learning environments, broadening participation in stem fields, and stem workforce development and by the science of science bpinnovate program. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Ecological legacy effects of megacarcasses in African savanna ecosystems

Awardee: Utah State University

Amount: \$350,371.00

Abstract: large animals such as elephants and rhinoceros, called "megafauna" for their extreme size, have outsized impacts on the ecosystems they live in. they engineer their environments by knocking down trees and grazing grasses to create large lawns, helping to form habitats that facilitate other animals. but, there is little research that addresses the impact that the carcasses of these megafauna, or "megacarcasses", have on ecosystems after they die. their carcasses represent huge sources of nutrients that have a long-lasting ecological legacy on the areas of ecosystems where their carcasses occur. for example, african elephants are the largest land animals, but almost nothing is known about how the nutrients from their massive carcasses (up to 6,000 kg) affect savanna ecosystems. this award asks the main question: how do elephant megacarcasses affect the ecology of african savannas? the work will address how these megacarcasses affect nutrient cycling in the soil by microbes, plant primary production and species

**\*\*diversity\*\***, and herbivory by vertebrate herbivores, such as zebra and giraffe, and invertebrate herbivores, such as grasshoppers. this research will support the mentoring of 1 postdoctoral scholar, graduate and undergraduate students in ecology as well as science communication and outreach. the main broader impact will be the production of a scientific documentary, the legacy of megaherbivores, which will follow the life and death of an elephant in the african savanna, that will put the life cycle of these elephants into broader ecological context, understanding how they impact ecosystems and the current implications for ecosystems facing their disappearance. to address the overarching question, the award will use elephant carcasses of different ages (up to 15+ years old) in kruger national park (knp), south africa. combining soil (physical, chemical and biological properties), plant (productivity and **\*\*diversity\*\***), and herbivore (vertebrate and invertebrate) surveys at 50 megacarcass sites along with greenhouse experiments, the award will assess how nutrient pulses from elephant carcasses drive integrated responses of ecosystem processes. importantly, the elephant megacarcasses are distributed across gradients of rainfall (375-700 mm) and soil fertility (less-fertile sandy, granitic soils vs. more-fertile clayey, basaltic soils) in knp. these gradients of rainfall and soil nutrients provide a robust experimental framework for testing how the abiotic environment impacts the ecosystem-level legacy effects of terrestrial megacarcasses. finally, by combining the data from the field on the effects of megacarcasses on ecosystem processes with a database of elephant population across knp, the researchers will use ecological modeling to show how the distribution of megacarcasses generates variability in ecosystem processes across the savanna landscape as elephants naturally die over time. this study will represent the first examination of the ecological legacies of megacarcasses on terrestrial ecosystems. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Diversity as an Organizational Capability: A Multilevel Examination of Board Composition and

## Firm Effectiveness

Awardee: Michigan State University

Amount: \$350,000.00

Abstract: in the midst of increasing legislation to diversify the boards of publicly held organizations, insight into why such **diversity** matters has remained relatively stagnant. several states have instituted requirements that the boards of public companies become more diverse in terms gender, race, and sexual orientation or provide evidence of the company's broader commitment to developing and maintaining board **diversity**. yet, while researchers have explored the performance impacts of board demographic composition, the findings remain equivocal given little attention to the mechanisms through which such relationships occur. this project endeavors to fill this gap within the **diversity** and strategy literatures to advance insight into the value of and for **diversity** in corporate governance. with a central hypothesis that board demographic **diversity** impacts organizational performance through experience-based **diversity**, this project will examine the effects of director demographic and experience-based characteristics on organizational strategic actions and financial performance. the project will utilize data on director and board characteristics across approximately 1,500 publicly traded firms in the u.s. over a ten-year period from 2007-2017. these data along with data on firm governance quality, strategic choices and firm performance will be obtained from several databases, including boardex, compustat, the institutional shareholder services (iss), ravenpack news analytics, and morgan stanley capital international (msci). director data will be aggregated and combined with firm-level data to estimate the effects of board **diversity** variables on firm organizational actions and performance. overall, this project offers an integrative, process-based perspective for understanding value creation and capture as it pertains to board **diversity**. by encouraging and establishing a future research agenda for a more systemic approach to the study of board **diversity** and firm performance, this project has the potential for enhancing the explanatory power and practical usefulness of future firm-level **diversity** research. more broadly, project has the potential for building **diversity**-related

partnerships between academia and industry and transforming the ways in which organizations approach **\*\*diversity\*\***. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: REU Site: Undergraduate Research Opportunities in Cave and Karst Science (U-ROCKS)

Awardee: James Madison University

Amount: \$349,914.00

Abstract: undergraduate research opportunities for cave and karst science (u-rocks) is a unique research experience for undergraduates (reu) site that gives students an opportunity to explore the multi-disciplinary field of cave and karst science. karst is a type of landscape where rocks (usually made of carbonate, like limestone) are dissolved by interaction with water. as the rocks dissolve, subsurface caves and underground river systems are created, and surface features such as sinkholes, disappearing streams, and springs may form. karst makes up about 20% of the land surface in the u.s., and nearly half of the drinking water in the us comes from karst groundwater sources (also known as karst aquifers). drinking water from karst aquifers is particularly vulnerable to contamination, and karst surface features can affect the ability to build on the land. therefore, specialists trained in cave and karst science, such as those who participate in u-rocks, are attractive not only in the academy, but for careers and work involving land management, water resources, transportation, and civil engineering. the recruitment process for this reu site will focus on the integration of students from historically underrepresented groups, including a cohort of 3-4 students per year from the university of puerto rico system, and a similar number from regional community colleges near james madison university. u-rocks reu site is designed to provide an original and independent well mentored undergraduate research experience, as well as a thoughtful approach to the students' personal and professional growth. the primary goal of the u-rocks program is to

provide a catalytic, intentional, and sustained experience for a diverse group of ten promising undergraduate students each year. this will be accomplished via four different pathways. first, the students will conduct mentored independent research projects working on projects related to karst over a broad range of disciplines; some example projects might involve the geophysical characterization of void spaces, isotopic geochemical analysis of stalactite samples to get at paleoclimate, analysis of a fragile cave ecosystem, and development of land use policy to protect water resources. secondly, we will organize scientific workshops in cave and karst science to provide a broad and solid foundation and give students opportunities to share their work with the cohort. thirdly, the workshops will have a strong personal and professional development component, with a focus on **\*\*diversity\*\*** and inclusion, scientific ethical behavior, scientific identity, belongingness, independence, and self-efficacy. finally, there will be a focus on building a diverse learning community through peer mentoring and social activities. the secondary goal of u-rocks will be to generate original, multi-disciplinary research related to cave and karst science, leading to abstracts and publications. this will be accomplished by strongly encouraging research projects and the mentor/mentee relationships to continue beyond the ten-week summer session. the tertiary goal of the u-rocks program will be to further enrich jmu's culture of undergraduate mentoring. this will be accomplished by offering a mentor workshop using the entering mentoring curriculum developed by christine pfund and others. mentors from four different reu programs housed within jmu's college of science and mathematics will be invited to participate in this roundtable workshop, enabling the sharing of experience and expertise to increase the mentoring capacity within the already formidable jmu community. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Proposal GEOPATHs:IN Recruiting through location-based Curriculum and Field and Laboratory Research Experience for High School Students, Teachers and Undergraduates

Awardee: University of Nevada Las Vegas

Amount: \$349,710.00

Abstract: this award is funded in whole or in part under the american rescue plan act of 2021 (public law 117-2). improvements to stem k-12 education and increasing the number and **\*\*diversity\*\*** of young people headed into stem careers have been identified as national priorities. this project seeks to address aspects of both of these priorities in the context of geoscience education and workforce

**\*\*diversity\*\***. the project will encourage high school students including many from historically excluded groups, to become involved in the geosciences or other stem disciplines by 1) engaging them in lesson plans developed by participating teachers to explain the local landscape and natural environment in which they live, 2) offering them opportunities to participate in geoscience research projects at the university of nevada, las vegas and 3) by building personal connections between students and faculty at unlv. to facilitate interactions with high school students pis will build long term relationships with high school earth science teachers by hosting summer workshops in which teachers will be provided with information about the local geology and natural environment and assist them in creating lesson plans for their classrooms. the activities will build up to a culminating experience where the teachers and high school students have an opportunity to claim their own identity as budding geoscientists.

this project will encourage high school students including many from historically excluded groups to become involved in the geosciences or other stem disciplines. the program will strengthen the relationship between the university of nevada (unlv) and the local community, including the local school district. project objectives will be accomplished through a comprehensive program that will include: 1) building a professional earth science learning community to facilitate collaboration between local high school teachers and unlv faculty/students; 2) generating high school earth science curriculum materials based on the local geologic resources that will provide stem education opportunities while also introducing potential career paths in the earth sciences; 3) creating a service learning course that will pair undergraduate ?geoscience ambassadors? with high school classes that are utilizing the newly developed curriculum materials; and 4) engaging highly motivated high school students, high school teachers, and unlv undergraduate students in high profile, locally relevant scientific research questions in a way that leverages cutting edge analytical equipment in the unlv geoscience department. the workshop curriculum content and materials will be designed in consultation with curriculum experts so that they mesh well with the teachers? needs and address concepts outlined in the nevada academic content standards for science. resultant outcomes will bear benefits to teacher and student

participants, faculty and the community as the project demonstrates how to build the geoscience workforce at the local level. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: ERASE-PFAS: A "concentrate-and-destroy" technology for treating per- and polyfluoroalkyl substances using a new class of adsorptive photocatalysts

Awardee: Auburn University

Amount: \$347,984.00

Abstract: per- and polyfluoroalkyl substances (pfas) have been manufactured and widely used in hundreds of consumer products and industrial processes for decades. release of pfas into the environment has resulted in drinking water supplies for millions of u.s. residents to become contaminated at levels exceeding united states environmental protection agency health advisory limits. unfortunately, conventional water treatment processes are not effective at removing or destroying pfas due to the unique molecular properties of these compounds. this has created an urgent national need for water treatment technology to address this problem. the goal of this research is to address this problem through a multi-phase research project focused on developing ?trap and destroy? technology. this technology utilizes a new class of adsorptive materials to efficiently capture pfass from water, followed by degradation using targeted ultraviolet and sunlight-assisted reaction. successful completion of this research will benefit society through the production of effective pfas treatment technology. additional benefits result from increased scientific

literacy through enhanced public awareness of pfas contamination, as well as by increasing the **\*\*diversity\*\*** of the nation's stem workforce by engagement of k-12, undergraduate, and graduate students from underrepresented groups in research and training. the overarching research goal of this project is to develop and fully characterize an innovative technology to cost-effectively remove and degrade pfas from contaminated water. the technology is based on a new class of adsorptive photocatalysts that can selectively adsorb pfas from water to the photoactive solid surface, and then destroy pfas in situ under uv or solar light. this project will target both legacy pfas and their newer substitutes such as genx. the research goals will be accomplished through a series of interconnected research tasks to: i) develop adsorptive photocatalysts optimized for treatment of a wide range of pfas, ii) characterize the speed, selectivity, and capacity of the adsorptive photocatalysts for pfas treatment, iii) characterize uv- and solar-light solid-phase photocatalysis of the pre-adsorbed pfas, and iv) explore ways to enhance photocatalysis through amendment with low-cost oxidants and manipulation of reaction conditions. the underlying reaction mechanisms will be investigated through all stages of the research using state-of-the-science microscopic and spectroscopic analyses of the materials, high-resolution spectroscopic analysis of the reaction products, and modern density functional theory calculations. a preliminary cost analysis will be carried out to assess the cost-effectiveness of the technology compared to alternative treatment options. successful completion of the project will potentially lead to an innovative technology that can cost-effectively treat low concentrations of pfas in large volumes of contaminated water. more broadly, the knowledge gained from this project will also advance our understanding of the synergistic effects of nanoscale hybrid phases and multiple redox cycles on the overall performance of reactive composite materials, and potentially transform our knowledge on fabrication and application of carbon-modified, multi-phase photocatalysts. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: 21 cm Reionization Science with the MWA

Awardee: Arizona State University

Amount: \$347,237.00

Abstract: the epoch of reionization (eor) is the period of time in the early universe when it is thought that the first stars and galaxies formed. understanding the physics of galaxy formation and feedback during the eor is one of the key goals of modern cosmology and astrophysics. observations of neutral hydrogen in the early universe have the potential to revolutionize our understanding of these first stars and galaxies. this work will improve data analysis with the Murchison Widefield Array telescope so that researchers can make significantly better detections of such faint signals, making the observations much more useful and providing a tool for researchers engaged in similar projects. in addition, this work will continue and expand the initiative to provide research experiences for non-traditional undergraduates. undergraduate research is an essential component in preparing students both for graduate school and for positions in the broader STEM workforce. providing this kind of research experience to non-traditional undergraduate students will enable more of them to go on to graduate school, increasing the **diversity** of the broader STEM community. this award supports the continued work of a successful eor analysis team. over the past four years innovations by the US Imaging Power Spectrum (PS) team have driven the field forward and have led to the deepest eor PS limits in the world. the investigators will make the next steps needed to reduce the limits by another order of magnitude with Murchison Widefield Array (MWA) data. specifically, this work will make improvements in PS analyses with the MWA that will lower limits on the signal strength by an order of magnitude, making deep cuts into the possible parameter space for eor models. this research will be invaluable for the entire 21 cm community. this award reflects NSF's statutory mission and has been deemed worthy of support through evaluation using the Foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: P2C2--The Changing Width of the Tropics in Past, Present and Future Climate

Awardee: Colorado School of Mines

Amount: \$346,427.00

Abstract: the research centers on the hypothesis that extreme warming, such as during the early eocene and under potential unmitigated climate scenarios, drives a substantial expansion of the tropical belt accompanied by poleward shifts in other aspects of the atmospheric circulation and large-scale hydroclimate. this interdisciplinary research integrates paleo-proxy data with climate modeling to investigate the changing width of the tropics during late paleocene and early eocene. the observational component of the research aims to provide a comprehensive paleocene-eocene hydrological data synthesis and data for a model-data comparison. the modelling component will analyze pre-existing coupled deepmip climate simulations of paleocene-eocene, conduct targeted atmosphere-only simulations to explore the sensitivity of the results to sea surface temperatures, and perform the data-model comparison. the poleward edge of the tropical hadley cell is a fundamental characteristic of earth's climate. the edge of the hadley cell marks the boundary between the tropics and extratropics - the earth's two main climate zones at the most basic level. observations reveal a poleward expansion of the hadley cell in recent decades, driving an expansion of the tropical belt with potentially significant implications for worldwide climate. the expansion has the potential to shift rain belts and cyclone tracks, expand deserts, and exacerbate droughts and wildfires. climate models simulate the tropical expansion, albeit at lower rates than what is observed. this raises important questions about the causes behind the expansion and the ability of models to simulate the expansion as well as questions surrounding the magnitude of the widening under future global warming. the potential broader impacts include involving graduate and undergraduate students will be involved in the project, a plan for improving **\*\*diversity\*\*** and inclusion through existing programs, and a creative visual science journalism film project. specifically, the **\*\*diversity\*\***

activities include collaboration with the women in science, engineering and mathematics program (wisem) by contributing hands-on activity modules for their annual outreach programs, participation in the girls lead the way program for high school students, and also providing science experiment modules for mines girl scout engineering day which welcomes 100 junior girl scouts to participate in stem activities. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: THE SCOPE AND SIGNIFICANCE OF TUNGSTEN ISOTOPE VARIATIONS: IMPLICATIONS FOR MANTLE EVOLUTION

Awardee: Rutgers University New Brunswick

Amount: \$345,352.00

Abstract: tungsten isotopic variations have been documented in modern and ancient rocks over the past decade, yet their role in constraining mantle evolution remains debated. this is because their origin and mode of preservation in the mantle are unclear. tungsten isotopic compositions, however, could provide unparalleled constraints on mantle evolution as tungsten is one of the few isotopic tracers able to track the final stages of accretion, early planetary differentiation, and potentially ongoing core-mantle interaction. to effectively utilize this tracer, the scope of tungsten isotopic variations must be robustly identified and incorporated into physical mantle evolution models. our

starting point is a survey of the most ubiquitous rock type sampling the mantle: mid-ocean ridge basalts. we will test hypotheses of the origin and preservation modes of tungsten isotopic anomalies in the mantle by synthesizing new and existing tungsten isotopic data with numerical models of thermochemical mantle convection. the proposed integration of data, techniques, and interpretations is novel and has the potential to significantly advance the understanding of mantle evolution beyond the tungsten isotope community. three additional broader impacts planned. (1) development of interdisciplinary partnerships by coordinating early career scientists who are experts in different disciplines. this includes support for a postdoctoral associate to conduct state-of-the-art research. (2) advancement of teaching and participation in science by providing a structured research program for an undergraduate student at rutgers university facilitated by the aresty research center for undergraduates and **\*\*diversity\*\*** and inclusion centers affiliated with the university. (3) further development of the planetary science research track at the department of earth and planetary sciences, rutgers university. with the recent discoveries of tungsten isotopic heterogeneity in ocean island basalts, it is now necessary to understand if mid-ocean ridge basalts possess tungsten isotopic variation and investigate what causes these variations. using proven analytical methods, we will measure high-precision tungsten isotopic compositions in samples from compositionally diverse mid-ocean ridges. this task will address the issue that little research has been reported to define mantle reservoirs which are purportedly normal for tungsten isotopic composition. to advance broader scientific implications provided by tungsten isotopic studies to the community, we will test the plausibility of the leading hypotheses of the origin of tungsten isotopic anomalies in the mantle by integrating our new and existing tungsten isotopic data with numerical models of thermochemical mantle convection. these results are anticipated to have broad implications for our understanding the dynamic evolution of our planet. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: PurSUIT: Species diversity and evolution of parasitic microfungi

Awardee: University of Colorado at Boulder

Amount: \$343,925.00

Abstract: fungi are essential to ecosystem functioning, occur virtually everywhere, and form complex relationships with diverse organisms including prokaryotes, algae, plants, invertebrates, vertebrates, and other fungi. nonetheless, fungi are the most undersampled and poorly documented major lineage of eukaryotes, even though total species estimates range conservatively from 1.5-6.1 million species. this uncertainty reflects numerous gaps in knowledge about fungal distributions, especially regarding range and extent of unculturable fungi, microscopic fungi (microfungi), parasitic fungi, and tropical fungi. this project will document **diversity** of fungi in two groups that represent major gaps in our knowledge: the first are unculturable microfungi that associate with insects, called labouls, and the other are unculturable microfungi that associate with plants, called rust fungi. members of labouls and rust fungi are expected to have profound effects on ecosystem health and functioning through both beneficial and harmful interactions with their animal and plant hosts. the research team will explore several global habitats in tropical and temperate regions that have not previously been surveyed for these fungi. it is expected that hundreds of new species will be discovered and described during this project. in addition to enhancing the documented bio**diversity** on the planet, this project will resolve the "tree of life" for both groups and use this information to resolve long-standing questions regarding the evolution of the fungi. broader impacts include graduate and undergraduate training, international workshops to enhance collaboration between us and local researchers, and outreach to the public through "bat night" and "roach hunt" field trips. these fungal lineages are being studied for several reasons: 1) both represent groups poorly documented from tropical world regions; 2) both represent groups that are not detected by commonly applied culture-based and high throughput sequencing efforts; 3) neither group has been resolved, phylogenetically, by application of multi-locus analyses of known species; 4) both represent

obligately parasitic lineages that are rarely studied but expected to have profound effects on ecosystems; and 5) both are or are related to heteroecious fungi (requiring two different hosts), a phenomenon that is extremely rare in fungi. a complementary team of us and other global experts on these fungi, ranging from junior to senior scientists, have designed an experimental approach that includes standardized sampling strategies from tropical and extra-tropical regions with multi-locus phylogenetic, phylogenomic, comparative genomic, and statistical analyses to: 1) determine whether accurate estimates from obligate microparasitic fungi, not included in any other estimates, will affect overall fungi species estimates; 2) whether parasitic microfungi follow the reverse latitudinal gradient posited for other fungal groups; and 3) resolve long-standing unresolved phylogenetic nodes by the incorporation of ?missing? lineages. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Testing the reduction of aerobic habitat as a common kill mechanism for major mass extinction events

Awardee: University of California-Riverside

Amount: \$342,080.00

Abstract: the project will study the response of marine animal ecosystems to environmental change using three mass extinction events from the geological record as study systems. specifically, the project will test the hypothesis that a large proportion of extinction during these events can be explained by the stresses that elevated temperatures and reduced oxygen availability place on animal respiration. geochemical data will be used to constrain computer simulations of changing ocean conditions during these mass extinction events. results from laboratory studies on animal respiration will then be paired with fossil data to assess whether differences in extinction intensity in space and across taxonomic groups can be explained by spatial variation in environmental change

or differences among taxonomic groups in their ability to withstand environmental change. the project will provide interdisciplinary training to a group of graduate students and post-docs. it will further impact stem education through the creation of a website that will allow access to model results so that students can visualize and explore model output to understand cause-effect relationships between continental configuration, ocean conditions, and biological **diversity**. the investigators will also offer short-courses on earth system modeling and data interpretation at major conferences that will be recorded for asynchronous use. the project will also involve the development of a podcast series addressing how we reconstruct the ancient earth system and use these reconstructions to better understand the present and predict the future. in this project, the hypothesis will be tested that the loss of habitat through constraints on aerobic respiration under climate change and ocean deoxygenation can explain the magnitude, taxonomic selectivity, and latitude variation in intensity for the late devonian (frasnian-famnenian), end-permian, and end-triassic mass extinction events. paleoredox and paleoclimate proxy data and geochemical indicators of diagenetic alteration will be used for both global average and local conditions before and after each major event combined with predictions from earth system models and occurrence data from the fossil record of marine animals to separate aspects of extinction that can be explained by physiological stress from those that require other explanations. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: REU Site: Increasing Native American perspectives in field and experimental linguistics

Awardee: University of Oregon Eugene

Amount: \$342,051.00

Abstract: this project is funded from the research experiences for undergraduates (reu) sites program in the sbe directorate. it has both scientific and societal benefits, and integrates research and education. the aim of this project is to make stem and higher education more accessible to and inclusive of american indian/alaska native students through a research experience that relates directly to a topic of particular interest to american indian/alaska native communities ? the revitalization and scientific study of native languages. american indian/alaska native students are greatly underrepresented in academia and this situation has remained virtually unchanged for decades. a growing body of research points to the importance and need for higher education to increase its cultural competency as a critical strategy for becoming accessible to underrepresented groups, such as american indian/alaska native students. conversely, academia cannot achieve excellence without perspectives from a **\*\*diversity\*\*** of backgrounds to inform and improve it. thus, the broader impact of this reu site is manifold: it uses a culturally informed and competent approach to introduce american indian/alaska native students to linguistics and the various research disciplines with which linguistics intersects; in doing so it contributes towards an increase in participation of american indian/alaska native students in higher education and research; and as a result, this project contributes towards strengthening academia broadly through a diversification of perspectives. through the reu site, participants complete research rotations in multiple areas of linguistics, specifically focusing on experimental linguistics and language documentation and revitalization. the program embraces a usage-based study of language within a community-centered cross-disciplinary approach, which is relatively novel in undergraduate linguistic training. reu participants are exposed to the full range of skills necessary to conduct research in linguistics. these

research rotations are supplemented with coursework in topics on descriptive and experimental linguistics and academic and professional development workshops. the workshops focus on providing participants with skills to initiate careers in stem, as well as pursuing master's and ph.d. degrees in linguistics or related fields. the fundamental goal of this work is to help students become active agents of innovation in stem through linguistics, seeking to break down disciplinary silos and reprioritize the societal value of science. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: CPS: Medium: RUI: Cooperative AI Inference in Vehicular Edge Networks for Advanced Driver-Assistance Systems

Awardee: Temple University

Amount: \$342,035.00

Abstract: artificial intelligence (ai) has shown superior performance in enhancing driving safety in advanced driver-assistance systems (adas). state-of-the-art deep neural networks (dnns) achieve high accuracy at the expense of increased model complexity, which raises the computation burden of onboard processing units of vehicles for adas inference tasks. the primary goal of this project is to develop innovative collaborative ai inference strategies with the emerging edge computing paradigm. the strategies can adaptively adjust cooperative inference techniques for best utilizing available computation and communication resources and ultimately enable high-accuracy and real-time inference. the project will inspire greater collaborations between experts in wireless communication, edge computing, computer vision, autonomous driving testbed development, and automotive manufacturing, and facilitate ai applications in a variety of iot systems. the educational testbed developed from this project can be integrated into courses to provide hands-on experiences. this project will benefit undergraduate, master, and ph.d. programs and increase under-represented

groups? engagement by leveraging the existing **diversity**-related outreach efforts. a multi-disciplinary team with complementary expertise from rowan university, temple university, stony brook university, and kettering university is assembled to pursue a coordinated study of collaborative ai inference. the pis explore integrative research to enable deep learning technologies in resource-constrained adas for high-accuracy and real-time inference. theory-wise, the pis plan to take advantage of the observation that dnns can be decomposed into a set of fine-grained components to allow distributed ai inference on both the vehicle and edge server sides for inference acceleration. application-wise, the pis plan to design novel dnn models which are optimized for the cooperative ai inference paradigm. testbed-wise, a vehicle edge computing platform with v2x communication and edge computing capability will be developed at kettering university gm mobility research center. the cooperative ai inference system will be implemented, and the research findings will be validated on realistic vehicular edge computing environments thoroughly. the data, software, and educational testbeds developed from this project will be widely disseminated. domain experts in autonomous driving testbed development, intelligent transportation systems, and automotive manufacturing will be engaged in project-related issues to ensure relevant challenges in this project are impactful for real-world applications. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Hominoid origins in a unique paleocommunity

Awardee: Case Western Reserve University

Amount: \$336,384.00

Abstract: this project advances knowledge about a crucial time in primate evolution when the ancestors of apes and humans are thought to have first diverged from other primate lines. a team of experts in paleoanthropology, paleontology and geology are conducting excavations and analyzing

fossils and paleoenvironmental data from a fossil-bearing site in order to better understand the environmental context for primate adaptations and ecological **diversity**. the project offers invaluable research and training opportunities to scientists and students, including individuals from groups underrepresented in stem, and provides opportunities for science outreach about human origins and climate change with local communities and the general public. an extraordinary new fossil primate site provides an opportunity to obtain new data related to the origins of the hominoids during the oligocene. the primary objective of the project is to characterize the species **diversity** and paleoenvironmental context for the site. the central hypothesis is that the earliest stem hominoids arose within unique ecological communities that were very unlike those of the later miocene hominoid radiations. the team of paleoanthropologists, geologists, and paleontologists carry out this work through additional fieldwork and analysis of the hundreds of fossils and geological samples already obtained. the goals are three-fold: (1) characterize the paleobiological disparity between hominoids and cercopithecoids in the mid-oligocene by analyzing functional disparity; (2) build out a robust geologic framework that integrates current and future fossil localities into a well constrained chronology; and (3) characterize the mammalian community **diversity** by contextualizing its taxonomic, functional, and phylogenetic composition. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Effects of experimental warming, disturbances, and species interactions on tropical tree community demography

Awardee: Oklahoma State University

Amount: \$334,985.00

Abstract: tropical forests are the most diverse ecosystems in the world with some forests having hundreds of tree species per hectare. the maintenance of this **diversity** is believed to depend

upon complex interactions among species. however, the relationships and interactions among species can be altered by climate change and disturbances such as hurricanes that disrupt resource conditions that govern seedling and sapling interactions in the forest understory. this project will combine a shade house experiment with novel molecular approaches to study how adult trees influence the interactions among seedlings of species on the forest floor beneath their canopies. in addition to disentangling how disturbances and warming may shift the strength and direction of relationships among species, this project thus investigates how plants can control plant-plant interactions by secreting specific molecules from their root tips. these secretions influence which micro-organisms become common and these micro-organisms in turn influence seedling success (either positively by promoting beneficial microbes, or negatively by promoting pathogenic microbes). specifically, seedlings of canopy trees will be grown in pots at different densities in a shaded greenhouse under a range of growing conditions to simulate global warming and changes in canopy cover (light) that occur with hurricane removal of the adult tree canopy. they will be grown in different combinations of density and with different combinations of the field based micro-organisms that typically associate with the roots of different species of adult trees. the outcome of this work will help us to better predict whether tropical forests will maintain their high level of **\*\*diversity\*\*** as the world's climate continues to change and how changes in light associated with canopy removal during hurricanes or cyclones can change species relationships. in addition to the scientific benefits, this project will offer educational and research opportunities to under-represented students. the study site has an established successful internship program, where recently graduated university students, primarily from puerto rico, are provided the opportunity to participate in research. they will be offered the opportunity for internships with the project and gain research experience from it. the team will also collaborate with a non-profit organization in puerto rico to coordinate field trips for elementary and middle school students to visit the research site and learn about the project. overall, this work will contribute to the scientific and broader community understanding of what tropical forests might look like in the future. the maintenance of tropical forest **\*\*diversity\*\*** is

hypothesized to rely on complex species interactions such as mutualism, predation/pathogen attack, and competition, that regulate seedling dynamics and tree species coexistence. these **\*\*diversity\*\*** maintaining processes could be fundamentally altered under projected changes in climate and disturbance regime, yet we have little understanding of how these factors will act independently or in concert to affect biological **\*\*diversity\*\*** in tropical forests. this project builds and expands upon an existing infrared warming experiment (tropical response to altered climate experiment, trace). based upon preliminary data, the team hypothesizes that the strength and direction of density dependence changes with warming and disturbances because of modifications in species interactions such as associations with mycorrhizal fungi (h1), and that plants can in part control these changes through root exudates (h2). this 2-year project combines a shade house experiment with -omic approaches to evaluate how changes in light, density, microclimate and microbes influence density dependence in different forest species. specifically, seedlings from tree species will be grown in pots subjected to two soil source treatments (e.g. soil from warming versus control plots at the trace site), four microbial treatments (no mycorrhizal fungi, no pathogens, no microbes, control), three densities (low, medium, high), and two light treatments (low and high). broader impacts of the study will fall into three main foci 1) provide research and educational opportunities in science, technology, engineering and math (stem) with an emphasis on **\*\*diversity\*\*** and inclusion, 2) community outreach and education, and 3) generate research that will provide insight into the future of tropical forested ecosystems in a changing world. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Disentangling biological and environmental drivers of diversification in the Andean flora

Awardee: University of Rhode Island

Amount: \$333,083.00

Abstract: the tropical andes of south america is one of the world's richest bio\*\*diversity\*\* hotspots. this \*\*diversity\*\* likely evolved due to the complex environmental and geological history of this region. however, exactly how plant \*\*diversity\*\* arose from the combination of mountain uplift, the development of new habitats, and species interactions is unclear. this research aims to understand how these factors led to plant \*\*diversity\*\* in cloud forests and high-elevation grasslands. the researchers will develop new software to compare plant genomes to understand the ancestry of four groups of flowering plants in the andes. the project will also result in new mathematical models to test the importance of different factors in shaping \*\*diversity\*\* in these plant groups. these new methods will have broad application to studies of bio\*\*diversity\*\* in the andes and beyond. additionally, this project aims to train the next generation of scientists in the study of bio\*\*diversity\*\* through a variety of interrelated activities, including: (1) a course for undergraduates to do guided genomic research; (2) collaborative training for students; and (3) computational training for diverse students. the project will first establish well-supported phylogenetic hypotheses for each of the four focal clades of andean plants using low-coverage and targeted genome sequence data. samples will be collected from colombia as well as museums. this work highlights the importance of natural history collections in cutting-edge biological research, and new fieldwork will add to those collections. a component of the research will be to develop new approaches to address complexities common in plant genomes, including polyploidy and paralogy, that can affect estimates of evolutionary relationships. these methods will be made available through open-source software such that other researchers can easily estimate phylogenies and examine support for phylogenetic hypotheses using sequence data. second, the project will develop new models that jointly infer the roles of dispersal and trait evolution in species diversification. these methods will be applied to phylogenomic, morphological, and distribution data collected for this project. these methods will also be made publicly available for widespread use. finally, by comparing the roles of biogeographic and ecological processes in generating \*\*diversity\*\* in these clades, the research will address the

generality or idiosyncrasy of the processes facilitating rapid radiation in tropical andean plants. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: IGE: Learning the Entire Pipeline: Analyzing and Improving Graduate Engineering Education through Communities of Practice

Awardee: North Carolina State University

Amount: \$332,184.00

Abstract: this national science foundation innovations in graduate education (ige) award to north carolina state university will support groundbreaking research on how graduate students in critical engineering domains learn to put academic knowledge into practice while working in diverse, interdisciplinary teams. in order to prepare students to transfer their classroom experiences to professional practice, engineering education needs to improve students' ability to work in multidisciplinary teams, deal with diverse opinions, ideas, and backgrounds, and broaden their education to understand the impact of engineering solutions in a global context. this project adopts a highly developed theoretical framework called "communities of practice" (cop) and applies, researches, and further extends cop theory in graduate classes across civil engineering, computer science, and electrical engineering. this approach has a strong emphasis on collaboration, teamwork, knowledge as doing, and communication across disciplinary and cultural backgrounds. by applying this approach in three engineering courses from three different engineering departments at north carolina state university, this project will yield insights around student interactions and learning within different team settings: 1) integration into a professional engineering environment, studying how students interact with professionals and how the academic and professional communities learn from their encounters; 2) engagement in interdisciplinary projects in teams that bring together two disciplinary communities; and 3) engagement in interdisciplinary projects with

teams that work on subsystems which need to be integrated into one working whole. this project will focus on how **\*\*diversity\*\*** plays out in cops, examine what factors lead to productive participation by all, what challenges inhibit participation and investigate approaches to structuring academic cops to support equitable learning and contributions by all. through this approach which involves various settings and granularities in three different courses, this project will develop a broader view of how engineering students learn in different team settings. the proposed approach can help to bridge the gap between theory and practice, facilitating the development of a workforce that can work within and across teams, projects, and domains. to help apply the proposed approaches to other disciplines, we will develop and disseminate a set of guidelines in our future publications and presentations. the innovations in graduate education (ige) program is focused on research in graduate education. the goals of ige are to pilot, test, and validate innovative approaches to graduate education and to generate the knowledge required to move these approaches into the broader community. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: RUI: Will climate change lead to system shifts on tropical mountains?: the interplay of epiphyte losses on host tree function, microclimate, and hydrology

Awardee: University of Utah

Amount: \$330,826.00

Abstract: tropical montane cloud forests (tmcfs) are important ecosystems to study and conserve due to their exceedingly high bio**\*\*diversity\*\*** as well as the critical roles these forests play in local and regional water cycling. deforestation in lowland regions and increases in global sea surface temperatures indirectly threaten these forests due to the lifting of the cloud base and an increase in drought conditions. epiphytes, i.e. plants that live on the surfaces of other plants, cover nearly all

tree surfaces in the tmcf and contribute substantially to ecosystem function due to their high capacity to capture and temporarily store water. unfortunately, these plants are the most vulnerable ecosystem components to projected changes in climate. a loss of epiphytes in the tmcf would lead to substantial bio\*\*diversity\*\* loss as well as a destabilization of water resources for human populations. this work aims to fill an important gap in the understanding of feedbacks among epiphytes and forest functions in the tmcf, and will provide important data for land-use and conservation workers as well as natural resource managers and governments in tropical montane regions concerned with long-term water security. a number of local and us-based workers and students will be trained in field and lab-based techniques and regular training events and exchanges will take place amongst all the participants. epiphyte gardens and accompanying curriculum will be created and placed in local schools to increase understanding and awareness of the connectivity between epiphytes and water cycling in the cloud forest.

tropical montane cloud forests (tmcfs) are under threat due to rapid changes in climate and in fact, recent work suggests that this ecosystem is predicted to contract substantially in the coming decades. this proposal addresses the question: how will a loss of the diverse and abundant epiphyte communities in the tmcf impact tree health, energy balance and hydrologic function? the investigators propose to conduct the first large-scale epiphyte removal experiment, in which trees in forest and pasture will be stripped of their entire epiphyte community. changes in crown-level microclimate (air temperature, relative humidity, leaf wetness, wind speed, solar radiation) as well as growth, water relations (water potential, sap flow, stomatal traits, carbon isotopes) and ecohydrological parameters (soil moisture, throughfall, stemflow) will be measured in and under the trees stripped of their epiphytes and compared with paired trees with intact epiphyte communities. direct field-based measurements will be coupled with remotely sensed parameters (ndvi, air temperature, leaf water content) using a high-precision drone outfitted with an integrated multispectral imaging system. a numerical model of epiphyte-host tree water relations will be developed and coupled to a land-surface hydrology model to scale up the field-based measurements and predict the effect of epiphyte loss on regional energy budgets and

canopy water cycling. field work will take place in five locations in the monteverde region of central costa rica. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Genetics and biomechanics of non-Newtonian prey capture adhesives across Panarthropoda

Awardee: University of Maryland Baltimore County

Amount: \$330,483.00

Abstract: several groups of invertebrate species produce prey capture glues that are deposited on

silks, secreted onto limbs, or squirted directly onto prey. these glues are materially unique in their drying times and reaction to humidity, but they are functionally similar in that they vary in viscosity based on applied forces and their rapid adhesion. the researchers will investigate the molecular and physical attributes of prey capture glues from 10 species in three distantly related groups - arachnids (spiders and opilionids), flies (predatory glow worms), and onychophorans (velvet worms). by understanding the differences in glue properties with respect to their molecular bases, a catalog of necessary components can be established for the design of new synthetic adhesives. this research will furthermore enhance participation of underrepresented minorities in field coursework, which research continues to demonstrate to be critically important to individuals choosing careers in ecology, evolution, and environmental sciences. the highlands biological station (hbs) in highlands, north carolina, is an important resource for research in the appalachian region and has hosted the two-week field class, "the biology of spiders," for several decades. this class focuses on field identification, specimen collection, and preservation. with the twin goals of furthering positive public perception and interest in arachnids within the appalachian region, and improving access to fieldwork opportunities for diverse student populations, the researchers will enhance the existing course by supporting student attendance via "diversity"-focused scholarships, new course material, and contributions to the hbs arachnid collection through student participation. unlike materials with homologous origin that diversify under selective pressure, investigating convergently evolved prey capture glues from distantly related organisms offers a unique opportunity to explore the necessary and novel components for constructing these adhesives. this project will examine prey capture glues with the broad goals of understanding the contribution of their molecular components to function, and discovering the commonalities associated with functional, ecological, or morphological similarity. first, targeted transcriptomics, dna sequencing, and glycosylation analyses will be employed to reconstruct the biomolecular organization of the glue from each species. this will be the first study to investigate the importance of glue gene length and repetitiveness for glue function, and the first comparison of posttranslational o-glycosylation modifications in a "diversity"

of bioadhesives. second, force transduction measurements during adhesive manipulation will allow documentation and analysis of the biomechanical properties of each glue. combined with full-length sequences, direct inference will be made about the mechanical potential of glue sequence, including the role of repeat number and unit complexity in contributing to adhesive toughness and extensibility. finally, we will reconstruct gene trees in order to evaluate support for parallel or convergent evolution of prey capture adhesives. similar sequence identity will support the convergent strength of functional selection in the evolution of prey capture glue genes. alternatively, poor sequence identity between glue transcripts indicates that a variety of biochemical mechanisms exist for prey adhesion, providing exciting novel pathways for biomimetic synthesis. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: SWIFT: Cognitive-IoV with Simultaneous Sensing and Communications via Dynamic RF Front End

Awardee: University of California-Los Angeles

Amount: \$329,999.00

Abstract: future transportation is promising safer and more efficient traveling via connected intelligence among vehicles as well as with the transportation infrastructure. at the same time, travelers can also be relieved from tedious driving and use vehicles as offices or entertainment rooms on the move. essential to all these is a reliable and resilient internet of vehicles (ioV). given the unique transportation environment, a satisfactorily functioning ioV is confronted with many challenges. for example, data services for transportation safety/efficiency and/or traveler convenience/comfort are often very sensitive to delays and require large bandwidth. the vehicular environments are also filled with various communication services as well as active sensing devices, which can potentially cause interferences to each other. in addition, the high mobility inherent to

transportation and fluctuation of the transportation information exchange depending on the specific traffic scenario can both lead to fast-changing and possibly unpredictable dynamics. to address these challenges, this project organizes collaborative efforts to enhance spectrum utilization, sharing and management in iov. the project will promote the interactions among multi-disciplinary experts such as electromagnetic waves, electronics, signal processing and wireless communications to create wireless innovations at different network layers. the developed technologies will provide valuable tools for foundational science and engineering research and promote societal embracing of the emergent cognitive iov technologies. the project also has an integrated education plan that aims to prepare the workforce to address future challenges of spectrum utilization and wireless communications, while promoting and embracing **\*\*diversity\*\*** in science and engineering. this project aims to develop a cognitive iov framework with simultaneous sensing and communications via a novel dynamic rf front end. targeting the aforementioned challenges, the proposed iov research has three distinctive features. first, the proposed research is centered at simultaneous communications and sensing. based on a dynamic rf front end that is innovatively designed to facilitate full duplex modes, communications and simultaneous monitoring of multiple spectrum bands with tunable granularity become possible. secondly, the resultant iov framework is cognitive in two counts: i) cognitive in the spectrum environment - the spectrum sensing information from devices equipped with the dynamic rf front end is used to develop algorithms to learn and track the spatiotemporal radio tomography with quantifiable uncertainty; and ii) cognitive in the physical environment - with judiciously designed waveforms that enable simultaneous communications and active physical environment sensing, the acquired information will be leveraged to enhance communications. last but not least, the proposed cognitive iov framework is dynamics-ready via hardware, architecture, and algorithm design: the dynamic rf front end boasts real-time tuning and control capability, the network architecture incorporates unmanned aerial vehicles (uav) to mobilize on-demand support for transportation/traveler data service hotspots, and reinforcement learning algorithms developed to achieve closed-loop control and management of spectrum resources will

remain robust when the dynamics are unknown or unpredictable. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: CNS Core: Small: Adaptive Smart Surfaces for Wireless Channel Morphing to Enable Full Multiplexing and Multi-user Gains

Awardee: University of California-San Diego

Amount: \$329,998.00

Abstract: the connectivity solutions need to scale up massively to support unprecedented exponential growth in data rates and the number of devices. the primary approach to meet the demands has been to upgrade the infrastructure, such as adding base stations with multiple antennas and/or upgrading clients. unfortunately, these approaches have fallen short of their goal as in practice, the channels between users and base stations have limited scattering or richness to enable spatial multiplexing, and users are not sufficiently separated in the spatial domain. this proposal will shape the channel to unlock the full potential of wireless networks without requiring updating the base station or user device at a low cost in terms of power and expense. the proposed research aims to adaptively modify and morph the wireless medium using smart passive reflector surfaces to materialize the spatial multiplexing gains. the underlying idea is to use smart reflectors to create additional channel **\*\*diversity\*\*** to manipulate the received signal before reflecting it to minimize interference at the receivers. the research brings together pis and techniques from communications theory, networked system design, and antenna design to build scalable and low-cost wireless networks. the project also proposes a synergistic educational and outreach plan that leverages the technical work to build exciting demos for undergraduate and k-12 classrooms. for example, a smart surface-based demo, which increases the data rate and coverage of current wi-fi devices, will introduce students to the wonders of engineering in a pragmatic yet compelling

way, with the hope of increasing **diversity** in stem-related education environments. the proposal would develop smart surface designs capable of morphing the channel, and develop the hardware prototype and algorithms to provide coverage and multiplexing gains to support massive numbers of users and the exponential increase in data rates. the designed smart surface with fine-grained control would allow us to morph the wireless channel or environment to increase the **diversity** and multiplexing gains as deemed necessary during optimization. we further establish smart surface placement theory and algorithms and quantify the performance-size trade-offs. we develop low-overhead channel estimation and low-latency optimization algorithms for the base station to support temporal channel changes and improve the data rate and connectivity. the proposed effort would develop the theory and algorithms for multi-user setups to ensure scalability with smart surfaces. the proposed work would enable the first low-cost, practical smart surface and algorithms supporting high-mobility users with significant data-rate improvements. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Awardee: Rowan University

Amount: \$329,493.00

Abstract: artificial intelligence (ai) has shown superior performance in enhancing driving safety in advanced driver-assistance systems (adas). state-of-the-art deep neural networks (dnns) achieve high accuracy at the expense of increased model complexity, which raises the computation burden of onboard processing units of vehicles for adas inference tasks. the primary goal of this project is to develop innovative collaborative ai inference strategies with the emerging edge computing paradigm. the strategies can adaptively adjust cooperative inference techniques for best utilizing

available computation and communication resources and ultimately enable high-accuracy and real-time inference. the project will inspire greater collaborations between experts in wireless communication, edge computing, computer vision, autonomous driving testbed development, and automotive manufacturing, and facilitate ai applications in a variety of iot systems. the educational testbed developed from this project can be integrated into courses to provide hands-on experiences. this project will benefit undergraduate, master, and ph.d. programs and increase under-represented groups? engagement by leveraging the existing **\*\*diversity\*\***-related outreach efforts. a multi-disciplinary team with complementary expertise from rowan university, temple university, stony brook university, and kettering university is assembled to pursue a coordinated study of collaborative ai inference. the pis explore integrative research to enable deep learning technologies in resource-constrained adas for high-accuracy and real-time inference. theory-wise, the pis plan to take advantage of the observation that dnns can be decomposed into a set of fine-grained components to allow distributed ai inference on both the vehicle and edge server sides for inference acceleration. application-wise, the pis plan to design novel dnn models which are optimized for the cooperative ai inference paradigm. testbed-wise, a vehicle edge computing platform with v2x communication and edge computing capability will be developed at kettering university gm mobility research center. the cooperative ai inference system will be implemented, and the research findings will be validated on realistic vehicular edge computing environments thoroughly. the data, software, and educational testbeds developed from this project will be widely disseminated. domain experts in autonomous driving testbed development, intelligent transportation systems, and automotive manufacturing will be engaged in project-related issues to ensure relevant challenges in this project are impactful for real-world applications. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: CSR: Small: Evolution of Computer Vision for Low Power Devices, Breaking its Power Wall and Computational Complexity

Awardee: University of California-Davis

Amount: \$328,084.00

Abstract: the accuracy of computer vision for object recognition and classification has surpassed human capabilities. adoption of brain-inspired convolutional neural network (cnn) models and the ability to train and execute these complex networks by modern graphical processing units (gpus) are the backbone of this progress. however, in terms of computational requirement, memory usage, and power consumption, the cnn solutions are extremely demanding. meanwhile, many interesting applications of computer vision - such as small robotics, a wide range of cyber-physical systems, and many smart devices on the internet of things - are resource constrained. this project aims to substantially lower the computational complexity, the average-case classification power and the latency of cnn-based vision, enabling its deployment to a much wider range of platforms. from a societal viewpoint, this study enhances the research, education, and **\*\*diversity\*\*** at george mason university (gmu) by involving graduate, undergraduate, minority and female students, and enriches several courses that are offered at gmu. the goals of this research project are as follows: (1) reformulating the cnn-based learning model into an iterative convolutional neural network (icnn) learning model that allows early classification and permits early termination via various thresholding mechanisms and developing a framework to use the contextual knowledge that could be extracted from earlier iterations to guide and reduce the computation of future iterations. (2) developing an approximate icnn coprocessor that supports approximation in memory and logic by exploring new approximation opportunities created by icnn, and enhancing the icnn to adjust and learn the approximate hardware behavior in addition to its intended functionality.

Title: REU Site: Culturally Responsive Research in Developmental Science

Awardee: University of Texas at Dallas

Amount: \$327,848.00

Abstract: this project is funded from the research experiences for undergraduate (reu) sites program in the sbe directorate. it has both scientific and societal benefits in addition to integrating research and education. currently, the majority of developmental research is conducted by and focused on monolingual, white individuals from middle-to-high income households. to address the critical need to expand developmental theories to incorporate underserved and underrepresented populations this project will train students from these understudied populations to become researchers who can provide rich and needed perspectives on developmental science. through participation in the university of texas at dallas's year-long reu, 30 students (10 per year) from historically underrepresented groups will learn the necessary tools to conduct high-quality research with real-world applications with families that are challenging-to-study, vulnerable, and underrepresented in the developmental science literature. thus, the project will advance the field of developmental science by increasing **\*\*diversity\*\*** in both the researchers and the children who are researched. students will be drawn primarily from the dallas/ft worth area, which compared to other similarly large cities in the u.s., has few research intensive 4-year institutions of higher learning, and few opportunities for students to gain high quality, first-hand research experiences. at least 50% of the students will be enrolled at one of dallas college system's 7 community campuses, and the remaining students will be enrolled at the university of texas at dallas . a large number of historically underrepresented college students attend the local community colleges and utd. in the fall, students will acquire skills needed for culturally-responsive research by taking an active role in the play with me program. play with me, a unique and important aspect of this reu's research experience, is a free 12-week parent/child (ages 0-3 years) community-based outreach program created by utd developmental scientists and specialists based on playful-learning research and directed by developmental specialists of utd's center for children and families. with mentorship from utd faculty, students will formulate new theoretically-driven research questions within ongoing data sets influenced by their play with me experience. in the spring, a faculty mentor team will guide students

as they collect and analyze data from families recruited from play with me. in the summer, students will learn to disseminate findings to academic (journals, conferences) and non-academic (newsletters, community outreach) audiences. fellows will also participate in brownbag discussions on professional development, including how to identify and apply to graduate schools, prepare for the gre, and identify academic career options. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: OCE-PRF Biological methane sinks in the deep ocean: Linking genomic diversity and ecophysiology in syntrophic methane-oxidizing consortia

Awardee: California Institute of Technology

Amount: \$327,228.00

Abstract: this award is funded in whole or in part under the american rescue plan act of 2021 (public law 117-2). microbes are the workhorses behind every biogeochemical cycle, where they control the availability of different nutrients and other compounds. methane seeps in the deep sea are one such system, where methane and other gases seep out from marine sediments, and they account for a significant fraction of the global methane budget. at these seeps, diverse microbial communities thrive and can metabolize the methane released from the seafloor. however, little is known about the specific forces and processes controlling the distribution of these microbes and their ability to perform their important metabolisms. this project investigates the links between microbial **diversity** and the environment in a methane-degrading system, focusing on consortia of anaerobic methanotrophic archaea (anme) and sulfate-reducing bacteria (srb). the results will clarify the fundamental determinants of microbial community composition and improve understanding of marine methane dynamics. the proposed work will engage the broader public in several ways. undergraduate students from backgrounds underrepresented in stem will be mentored over a

summer research project through the caltech wave program. the researcher will also partner with local elementary, high school, and undergraduate-serving programs through the caltech ctl&o office and the center for environmental microbial interactions (cemi) to encourage student participation in research opportunities related to the proposed work. through existing collaborations between the ansep program and the orphan lab, the researcher will participate in the ansep middle school career exploration in marine science program. this project aims to identify 1) how the genomic **\*\*diversity\*\*** of anme/srb partners is structured across scales ranging from individual consortia to environmental gradients and 2) the genes and ecological factors determining ecological outcomes for each partner. samples containing anme/srb consortia have been previously obtained from methane seep sediments with a range of biogeochemical parameters. individual consortia will be sorted and sequenced to produce high-quality metagenome-assembled genomes (mags) for comparative analysis to reveal the strain-level composition of individual consortia and the proportion of each strain across different sediment samples to different methane seeps. functional profiling of mags will then allow comparative genomic approaches to identify the genes most likely to be critical to each population's success in each environment. predictions will be experimentally tested by a range of laboratory experiments including nanoscale secondary ion mass spectroscopy (nanosims), bioorthogonal non-canonical amino acid tagging (boncat), and fluorescence in situ hybridization (fish). the genes and associated ecophysiology identified here will result in greater understanding of the factors controlling methane at seep- and basin-scales, and more broadly, the generalizable principles of how microbes adapt to heterogeneous environments. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: RCN: Intermittent River Research Coordination Network (IRRCN): Integrating Intermittent River Ecology and Hydrology

Awardee: Pennsylvania State Univ University Park

Amount: \$326,564.00

Abstract: life is simply different in the absence of water, especially for life in rivers and streams. yet half of the earth's rivers dry or stop flowing each year. these streams or rivers are called "intermittent." intermittent rivers are not well studied or understood by researchers studying river ecology or river hydrology. initial research shows the hydrology and ecology of intermittent rivers are very different from rivers that always flow. the current scientific understanding and concepts of streams and rivers is incomplete as it is biased towards the half of the earth's rivers that continuously flow. the intermittent river research coordination network (ir-rcn) will organize a series of expert workgroups that will synthesize the growing body of research on intermittent river hydrology and ecology. these workgroups will produce generalized frameworks that can explain how intermittent river hydrologic and ecologic systems work. this research is important because intermittent rivers are often overlooked or excluded from water management plans due to uncertainty about their hydrologic and ecological importance. graduate students will receive interdisciplinary training in hydrology and ecology and network with intermittent river ecologists and hydrologists across the globe. funds will be provided by this award to form three workgroups on intermittent river hydrology, ecology, and ecohydrology. the hydrology workgroup will seek to generate new tools to characterize intermittent river flow regimes, develop a hierarchical scale-based framework for predicting spatial intermittence patterns, and compare statistical and process-based models for prediction of intermittent river streamflow metrics. the ecology workgroup will synthesize large scale intermittent river bio\*\*diversity\*\* and ecosystem datasets to better understand the structure and function of intermittent river ecosystems. the ecohydrology workgroup will integrate products from the ecology and hydrology workgroups to identify hydrologic controls on intermittent river ecosystems and integrate these findings into our current river conceptual frameworks designed for rivers that always flow. the ir-rcn will improve the management of intermittent rivers by enhancing communication and networking among academic researchers

and nonacademic stakeholders, including government agencies and ngos. datasets, methods, materials and projects produced by the ir-rcn will be made open access on the ir-rcn web portal and deposited in the dryad digital repository for long-term availability, which will broadly impact the global scientific community. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Engaging K-12 Teachers to Help Build a Cybersecurity Workforce Pipeline

Awardee: Forsyth Technical Community College

Amount: \$326,300.00

Abstract: this project addresses a growing need for cybersecurity professionals in the piedmont triad region of north carolina, an expanse of urban and rural communities anchored by the cities of winston-salem, greensboro and high point. the project will focus on bolstering the academic capacity required to expand the talent pipeline of cybersecurity professionals to serve business and industry needs across the 12-county region. local middle school and high school faculty will be enrolled in a 16 credit-hour program at forsyth technical community college (ftcc) that will prepare them to integrate cybersecurity principles into their classrooms. upon program completion, the teachers will have the knowledge and skills they need to be effective teachers of dual-enrolled high school students, which will result in an increase in the number of students who are prepared and motivated to enroll in a two-year program in cybersecurity. the teachers will also be prepared to earn cybersecurity certifications that will qualify them to serve as adjunct faculty at ftcc and will increase the college's capacity to provide post-secondary and workforce-related instruction in cybersecurity.

three goals guide the project team's efforts. first is to increase the number of cybersecurity professionals in the piedmont triad region. second is to increase the number and knowledge level of cybersecurity faculty at the secondary and post-secondary levels. third is to improve the \*\*diversity\*\*

of the cybersecurity workforce in the piedmont triad region. the project expects to see several outcomes from its efforts. one is to enable ftcc to increase awareness of cybersecurity first principles and practices. another is to develop lasting and effective partnerships for innovative cybersecurity education. additionally, the college envisions keeping the talent pipeline filled with well-educated, multi-skilled, work-ready graduates who will be able to help satisfy a projected national shortage of 1.8 million workers by 2022. the project will leverage options available to north carolina educators to seamlessly link dual-enrollment opportunities for high school students with the automatic transfer of credit awarded by community colleges. through project's collaboration with business and industry leaders, teachers will develop deeper insights into the role of cybersecurity across academic disciplines. this project is funded by the advanced technological education program that focuses on the education of technicians for the advanced-technology fields that drive the nation's economy. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: OCE-PRF: Cliff Hangers: Investigating Effects of a Submarine Canyon on the Distribution and Behavior of Midwater Animals and their Predators

Awardee: Monterey Bay Aquarium Research Institute

Amount: \$325,738.00

Abstract: this award is funded in whole or in part under the american rescue plan act of 2021 (public law 117-2). the deep open ocean waters house the largest animal communities on our planet. these communities remain largely understudied but are known to provide critical services including carbon export from the surface ocean into the deep-sea and feeding economically and socially important fish stocks and marine mammals. these midwater animals are the key link between the base of the marine food web and important predators, which rely on finding and exploiting dense prey aggregations. however, relatively little information currently exists about the oceanic

mechanisms or the ecological drivers that shape the distribution patterns of these important prey. submarine canyons are common features along coastlines that link the deep open ocean with the nearshore ecosystem. they are hotspots of both biological and human activity. this project will examine the role of a submarine canyon on the distribution, density, and **diversity** of the midwater community and subsequent impacts on the abundance and habitat-use of top predators with a combination of acoustic, visual, and biologging techniques. this project will support the training of a post-doctoral researcher and support the recruitment and retention of women in stem by providing resources to further the development of a continuous support network for local female-identifying stem community college students transferring to the local public 4-year university. the results of this project will also be shared with the public through a bilingual digital exhibit at the seymour marine discovery center in santa cruz, ca. the deep midwater (200-5000 m depths) is the largest habitat on our planet and represents over 90% of the entire biosphere, yet it is still one of the least understood and most mysterious ecosystems. deep pelagic communities are now known to provide critical ecosystem services including carbon export from the surface ocean with sequestration in the deep-sea and provisioning predators like economically and socially important fish stocks and marine mammals. however, relatively little information currently exists about the oceanic mechanisms or the ecological drivers that shape the distribution patterns of these important mid-trophic level animals. submarine canyons are common abrupt bathymetric features that bring together normally separated deep oceanic and shallow nearshore communities and have profound influences on coastal ocean dynamics and ecosystems. canyons are often hotspots of both primary production and predator activity. this project will investigate the role of submarine canyon bathymetry on the distribution, density, **diversity**, and composition of the midwater community linking these two trophic levels and the subsequent impacts on the abundance and habitat-use of top predators. this project will compare communities at a canyon wall site and at a midwater time series site, identify the oceanographic drivers and mechanisms driving variability in the near-wall community, and determine the relationships between predator distribution and canyon bathymetry

through a combination of acoustic, visual, and biologging techniques. current knowledge of the linkages between deep midwater and shelf communities remains limited, but increasing anthropogenic stressors like fishing, pollution, and climate change demand ecosystem-based solutions fundamentally based on understanding these interconnections. by investigating the mechanisms and drivers of the relationships between bathymetry, oceanographic conditions, deep water pelagic prey, and their predators, this project will help to address this knowledge gap, and the results will have important implications for the management and conservation of groundfishes and marine mammals. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research:SWIFT:Ultra Wideband Flexible MIMO Radios for Energy Efficient Secure Spectrum Sharing

Awardee: Ohio State University

Amount: \$324,999.00

Abstract: worldwide growth in wireless links, navigation, automation, internet of things (iot), and mobile healthcare has challenged spectrum access. in parallel, we are witnessing rapid advances in augmented reality/virtual reality (ar/vr), autonomous driving and vehicle-to-vehicle communications (v2v). further, increased adaptation of unmanned aerial vehicles (uav) may require large swaths of bandwidth and high data rates. indeed, the **\*\*diversity\*\*** of radio spectrum utilization is quickly growing. however, existing wireless networks may no longer be able to keep pace with these technologies, implying a need for new rhythms and targeted innovations. concurrently, security protocols must be adapted to avoid eavesdropping and man-in-the-middle (mitm) attacks. coexistence of active and passive spectrum utilization is another challenge. to address the aforementioned challenges, and to circumvent radio spectrum scarcity, this research brings forward

innovations and features to significantly advance next generation wireless networks. among them: 1) increased throughput using robust spectrum sensing and slicing of legacy frequency bands by identifying gray and white spaces/gaps across the available electromagnetic spectrum; 2) frequency independent and high isolation antenna feeds and rf cancellers to enable spectrum co-existence; 3) wideband autonomous multiple-input-multiple output (mimo) transceivers using flex radio architectures to maximize overall spectral efficiency; 4) significant hardware reduction via multiplexing; and 5) resilience against man-in-the-middle attacks via artificial intelligence (ai) techniques. this project will also foster workforce development in the rapidly growing area of wireless engineering. curriculum enhancements are proposed to integrate new technologies on spectrum awareness, wireless security, and cross layer rf transceiver architectures. further, new degrees and new curricula in wireless and iot technologies will be leveraged to promote stem outreach programs and coordinate outreach activities. the latter will be aimed at recruiting larger cohorts of undergraduates and k-12 students from the local miami-dade and broward counties to be trained in wireless engineering. examples of outreach programs to be leveraged include engineers on wheels, engineering expo, enlace (engaging latino communities for education), and the miami prep (positive youth preparedness) programs. the proposed research aims to develop next generation flexible and secure wireless networking with adaptive rf front ends and back-end cross-layer algorithms that enable spectrum efficiency and high throughput via novel relay architectures, all with end user protection in mind. namely, a new class of low cost and low power secure mimo transceivers with >100 db transmit/receive isolation are proposed along with flexible radio architectures. the following innovations are proposed: 1) ai-based effective spectrum utilization and/or coexistence, 2) innovative transmitter and receiver technologies through cross-layer design, and 3) improved security by detecting man-in-the-middle attacks and other eavesdroppers. notably, the transformative nature of the proposed research stems from the introduced novelties to overcome challenges in developing low-power and low-cost flexible radio architectures and rf electronics with secure data relays to provide resilience for man-in-the-middle attacks. to accomplish the proposed

goals, a strong background is required in the following areas: rf front/back-end hardware, mathematical network modeling, propagation, optimization, control, queuing, stochastic analysis, and legacy system operation integrated through the following thrusts: 1) rf reconfigurability and spectrum aggregation to support users with decoupled phy/mac protocols, 2) adaptive flexradio wireless networks with increased throughput and protection using high performance phy/mac layer algorithm, 3) rf self-interference cancellation for spectrum co-existence, and 4) ai-based models for security and privacy. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: DMREF: Microstructure by Design: Integrating Grain Growth Experiments, Data Analytics, Simulation, and Theory

Awardee: Illinois Institute of Technology

Amount: \$324,817.00

Abstract: most technologically useful materials are polycrystalline microstructures composed of a myriad of small monocrystalline grains delimited by grain boundaries. an understanding of the evolution of grain boundaries and associated grain growth (coarsening) is essential in determining the properties of materials across multiple scales. despite tremendous progress in formulating microstructural models, however, current descriptions do not fully account for various grain growth mechanisms, detailed grain topologies and the effects of different time scales on microstructural evolution. as a result, conventional theories have limited predictive capability. the goal of the project is to develop a predictive theory of grain growth in polycrystalline materials through the construction of novel, closely integrated data-driven numerical simulation and mathematical modeling combined with data analytics, analysis, and a set of critical experiments. this interdisciplinary project, requiring the complementary expertise of applied mathematicians and materials scientists, is firmly aligned

with the materials genome initiative. the new knowledge and tools that will emerge from the project will have a profound impact on the performance and reliability of polycrystalline materials used in many technologically useful systems and structures, thereby expediting advanced materials development and deployment. predictive computational algorithms and data will be made available and accessible to other researchers. for the training of the next-generation materials workforce, in addition to mentoring of graduate and undergraduate students, the pis (from columbia university, illinois institute of technology, lehigh university and university of utah) will participate in outreach activities and will continue to work towards increasing **\*\*diversity\*\*** and broadening participation within stem. grain growth is a very complex process and may be viewed as the anisotropic evolution of a large metastable network. one of the main thrusts of the project will be to uncover possible stochastic processes that define the evolution of various statistical measures of grain growth, discover relations among them, and establish links to materials properties. results from structure-preserving numerical simulations alongside critical sets of experiments and new experimental data will be invaluable in navigating the modeling and analysis. the project will also create and employ specific data analysis techniques for the study of dynamic evolution of grains in experimental and computational systems with the goal of validating and further refining the microstructural models. this component of the project, will lead to a) the development of new materials informatics methods, b) innovative stochastic differential equations/differential equations models of grain growth, c) new mathematical and numerical analysis techniques for coarsening systems, as well as d) improved computational tools. in turn, the results of combined data analytics, modeling and analysis will be used to guide the design of subsequent experiments. experimentally, grain growth will be examined in prototypical metallic thin films (pd, ni, cr, fe). as most elemental metals and many metallic alloys have cubic structures, the proposed studies will have broad applicability. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Elucidating the Nature, Causes and Climate Importance of the Mid-Cenozoic Loess in the Western USA

Awardee: University of Texas at Arlington

Amount: \$323,787.00

Abstract: loess deposits consist of fine-grained, windblown sediments and contain critical information about continental aridification processes that are key to understanding biotic evolution and climate change. this project integrates field data collected from loess deposited ~37-30 million years ago in wyoming, nebraska and montana, laboratory analyses, and paleoclimate simulations to understand the nature, causes, and paleoclimatic importance of these loess deposits. the research will advance stem **\*\*diversity\*\*** by supporting a two-day geocamp for historically underrepresented high-school students from east texas. in addition, this project will promote further development of the high-resolution community earth system model to be used to better understand ancient climate changes. this project will include field sedimentological observation and lab analyses of bulk sediment and quartz grain-size, quartz surface morphology, detrital and high-precision zircon u-pb geochronology to study the ancient loess deposits in wyoming, nebraska and montana, usa. these proxy data will constrain the extent, timing, pattern and characteristics of the loess; and determine sediment provenance and sediment recycling mechanisms. these proxy data will be integrated with a coupled atmosphere-land model to simulate changes of regional climate and vegetation induced by topography changes, global climate cooling, glaciation and shoreline regression to understand the cause and climate significance of the loess. in additional to gaining fundamental understanding of the loess deposits, the project will shed light on 1) the influence of climate change on biotic evolution at the eocene-oligocene transition (~34 million years ago); 2) the validity of different models of surface uplift in the western usa; and 3) the potential positive climate feedback of enhanced mineral dust emissions on global cooling at the transition. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's

intellectual merit and broader impacts review criteria.

Title: Examining the Role of Racial Identity and Personal Experiences in Equity-focused Computer Science Learning

Awardee: WestEd

Amount: \$323,305.00

Abstract: this project will explore the significance of race and equity in secondary computer science (cs) education. despite the importance of cs across all aspects of life, there is little racial \*\*diversity\*\* in the field along the pipeline from elementary school to industry. at the secondary level, even students who are highly interested and confident in cs remain underrepresented in the field. to address this problem, researchers have created culturally responsive computing approaches to effectively engage more students in cs. however, progress in implementing these approaches is limited by the low number of experienced cs teachers. this project aims to support secondary teachers in developing both subject matter knowledge and racial equity strategies for teaching cs. the first of three goals is to develop a set of professional learning activities that vary in the ways they address cs subject matter and racial equity topics. the second goal is to examine how well each activity engages teachers in learning and talking about cs content, race, and equity pedagogy. the principal investigator will collaborate with an urban school district to deliver the activities during the district's monthly cs teacher meetings. the third goal is to interview teachers to learn how their racial identity and past experiences in cs and in teaching influence their participation in the activities. the project aims to identify the most effective activities for learning about both racial equity and cs subject matter. the outcomes of this project may support other researchers and teacher educators to train more teachers who are equipped to provide equitable cs learning experiences for all secondary students. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: REU Site: Research in Behavior Science at West Virginia

Awardee: West Virginia University Research Corporation

Amount: \$323,027.00

Abstract: this project is funded from the research experiences for undergraduates (reu) sites program in the sbe directorate and the established program to stimulate competitive research (epscor). it has both scientific and societal benefits, and integrates research and education. the reu site for research in behavior science at west virginia university provides high-quality research experience and mentorship to students who aspire to be a part of the next generation of behavior scientists. this project aims to foster interest and participation in experimental psychology and expand the **\*\*diversity\*\*** of skilled researchers in behavior science. recruitment is open to nsf eligible undergraduate students as rising sophomores, juniors, and seniors, and this reu site especially encourages applications from undergraduate psychology majors from primarily undergraduate institutions in the appalachian region and students from underrepresented groups within psychology, including individuals from underrepresented racial and ethnic groups (e.g., black, indigenous, and persons of color), veterans, individuals with disabilities, first-generation college students, and students from socio-economically depressed areas. reu participants conduct laboratory research in behavior science with a focus on ?bench science? in behavioral psychology and the translation of basic research to issues of social significance. participation fosters scientific, communication, and collaboration skills. the research projects address questions relevant to several areas in behavior science, including behavioral pharmacology, prevention of relapse and maladaptive behavior, social behavior, and improving the efficacy of behavioral interventions. the findings of these studies contribute to a more advanced understanding of fundamental behavioral processes and technologies of behavior change. the long-term goal of this project is to foster student interest and participation in experimental psychology and expand the **\*\*diversity\*\*** of skilled researchers in

behavior science. the objectives toward meeting this goal include: 1) provide research opportunities to students from primarily undergraduate-serving institutions and students from underrepresented groups, 2) involve students in laboratory research in psychology with an emphasis on experiences that students may not have the opportunity to gain at their home institutions, including bench and translational research in behavioral psychology, 3) improve students' technical research skills, including idea development, research design, technical laboratory skills, and the dissemination of research, and 4) retain participants in the field of psychology by providing relevant experience, support, and encouragement to pursue graduate studies or other post-baccalaureate opportunities within psychology and related fields. each year, a cohort of 8 reu participants work with faculty research mentors from wvu's behavior analysis program in the department of psychology. during the 10-week experience, reu participants attend a 3-day training, conduct a research project with their mentor, attend research meetings, participate in a weekly seminar and a physical computing workshop, attend multidisciplinary workshops, and present at a research symposium. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: LTREB Renewal: Long-Term Dynamics of Amphibian Populations Following Disease-Driven Declines

Awardee: University of California-Santa Barbara

Amount: \$321,586.00

Abstract: this project will examine the processes of invasion of a novel pathogen into a population for the case of a fungal pathogen that causes the disease chytridiomycosis in frogs and salamanders. outbreaks of emerging infectious diseases are increasingly recognized as major threats, not just to human populations but also to wildlife, and they increasingly threaten global bio\*\*diversity\*\*. the initial invasion of a novel pathogen into a susceptible host population can cause

a disease outbreak resulting in high levels of mortality and declines in population size. when this happens, natural selection can occur for both the host and pathogen populations resulting in evolutionary changes in the host's susceptibility and tolerance to infection by the pathogen and the pathogen's ability to damage the host (virulence). these changes can in turn determine whether the host population can persist and recover from the disease. understanding these evolutionary processes is crucial in development of conservation strategies for threatened species. chytridiomycosis has had catastrophic effects on amphibians worldwide, and has been linked to numerous species extinctions in recent decades and many more species at risk. the researchers will investigate the patterns of evolutionary change in both the pathogen and the host (mountain yellow-legged frogs), following the invasion of the disease into hundreds of high elevation lakes in the california sierra nevada. this project will contribute to the understanding of the role of infectious diseases, such as chytridiomycosis, as agents of evolutionary change in natural populations. it will provide critical information to state and federal agencies, facilitating endangered species recovery and will train and educate undergraduates, graduate students, and the general public. this research builds on data from a long-term study of the population dynamics of mountain yellow-legged frogs (*rana sierrae* and *rana muscosa*) in the complex landscape of the california sierra nevada, and the affects of *batrachochytrium dendrobatidis* (bd) as it has invaded and spread through hundreds of frog populations. in most cases, invasion of bd results in outbreaks of the disease chytridiomycosis, rapid frog population declines, and local extinctions. in some cases, long-term persistence of frog populations occurs with bd in an enzootic state in which the impact of the pathogen is greatly reduced. the research will extend and leverage 25 years of host population and disease data and archived genetic samples from *r. sierrae*/*r. muscosa* and bd. these resources will provide insight into how populations of both host and pathogen change during the transition from pre-pathogen arrival, to disease outbreak, to enzootic disease, to potential recovery of the pre-disease host population abundances. this dataset will be used to investigate the genetic basis for differences in host resistance/tolerance and pathogen virulence. cutting-edge genomic analysis

of existing frog and fungal samples will complement laboratory experiments on bd virulence and frog susceptibility using bd cultures and frog mucosal samples from wild host populations. continued surveys of wild host populations will identify new disease outbreaks and describe the transition from initial outbreak to persistent enzootic state. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Exploring mechanisms of plasticity and tolerance in early stage marine invertebrates in response to marine heatwaves

Awardee: University of California-Santa Barbara

Amount: \$321,379.00

Abstract: marine heatwaves (mhws) ? prolonged periods of unusually warm surface seawater temperatures - have increased in intensity and frequency in us coastal waters. recent mhws on the us west coast have resulted in changes in species distributions, loss of bio\*\*diversity\*\* and closed fisheries due to harmful algal blooms. as the frequency of mhws increase, these events will continue to impact natural marine ecosystems and important resources from the ocean (e.g., fishing and aquaculture). the goal of this project is to better understand how mhws will affect coastal marine communities like kelp forests. a key missing piece of information is how early life-history stages, the stages that disperse and maintain healthy populations of marine organisms, fare in response to these anomalously high ocean temperatures. this project is investigating the response and resilience to mhw stress in embryos and larvae of two key marine invertebrates, the red and purple sea urchins that inhabit the kelp forests of coastal california. the red urchin is a valuable fishery (the roe is sold as uni) and data from this project is contributing to the management of this natural resource. lastly, the project is training early career researchers, undergraduate and graduate students with a focus on broadening participation in the fields of science and technology. the broader impacts are

providing research experiences and mentoring to under-represented undergraduates at uc santa barbara, a hispanic-serving institution since 2015. the project directly supports the phd dissertation research of three women ph.d. graduate students from under-represented groups. this project aims to understand the consequences of anomalously high temperatures during mhw events on reproduction and early development of marine organisms. in the coastal california system, marine invertebrates of the kelp forest ecosystem are reproductive when mhws tend to occur and intensify. the major goal is to examine how maternal and paternal effects, that play out in a mhw context, influence the thermal tolerance of early developmental stages of two sea urchin species from the temperate kelp forest communities of coastal california, the purple (*strongylocentrotus purpuratus*) and red (*mesocentrotus franciscanus*) sea urchins, the latter being an important wild fisheries species. this project is addressing climate-change relevant aspects of larval ecology and is examining how phenotypic plasticity contributes to adaptive capacity of marine organisms. a series of traits are being assessed for each species: (1) fertilization kinetics, (2) successful developmental progression, (3) thermal tolerance (via thermal tolerance trials and biochemical indices of thermal stress), and (4) parental effects. gene expression using rna sequencing is capturing the influence of maternal effects to address whether females that experience mhw temperatures in situ during gametogenesis produce progeny with greater thermal tolerance via changes of the larval transcriptome. this project is jointly funded by the biological oceanography and integrative ecological physiology programs. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Audio for Inclusion: Uncovering Marginalized Student Narratives to Provide Insight to Faculty on the Known Unknowns of Inclusion

Awardee: Florida International University

Amount: \$320,642.00

Abstract: this project will bring the experiences of diverse engineering students directly to faculty through edited audio interviews. undergraduate engineering education is a critical juncture in the diversification of the engineering workforce. however, engineering educational culture can marginalize many groups. faculty are key change agents in this culture, and their empathy and understanding for diverse students are critical for enabling and promoting inclusive education. however, faculty may not be aware of diverse student perspectives, and even well-intentioned faculty may fall short of creating inclusive classroom environments. more resources are needed to help develop faculty empathy and understanding for a broad range of student populations in engineering education. qualitative research presents a promising tool for centering the voices and experiences of students, but researchers' typical long form journal publications for disseminating qualitative research are not an accessible and compelling medium. to increase collective impact, more accessible, innovative, and timely dissemination strategies are needed. podcasts and youtube clips can be used to disseminate research findings with more immediacy and personalization than written text. this study will feature these audio formats as media to share diverse student experiences with faculty and to facilitate a broader impact on pedagogy and culture. faculty who listen to the audio will have the potential to gain reflective awareness of student experiences that provoke the creation of more inclusive classrooms. this novel dissemination approach will be sustained through the creation of a widely distributed podcast called audio for inclusion, hosted by the pis. this podcast will include the final versions of edited audio files generated in this study and will be located on the asee \*\*diversity\*\* committee's web and youtube pages, and incorporated into workshops. the project will conduct a nationwide recruitment of students with salient minoritized identities via email distributed through relevant organizations, campus support centers, and snowball recruitment. twenty (20) students will be interviewed twice throughout the duration of the study using a semi-structured protocol that focuses on their experiences in engineering education. interviews will be transcribed, de-identified, edited for conciseness, and re-recorded by student actors. recorded

interviews will be disseminated using a survey distributed to 100 faculty members who represent a range of familiarity with **diversity** and inclusion topics. this survey will prompt faculty participants to listen to embedded student narratives and provide feedback using likert-type and open-ended response questions. survey results will be used to observe the impact of the audio resources on faculty views of **diversity**, equity, and inclusion in engineering. this project will be informed by existing theoretical frameworks such as intersectionality, figured worlds, narrative, and critical theorizing. findings from this work will contribute to the knowledge base on broadening participation in engineering in three ways: (1) by providing insights into the experiences of students belonging to minoritized identity groups; (2) by developing an accessible resource for improving faculty knowledge of and strategies for promoting the inclusion of students? undisclosed identities and experiences in engineering education; 3) by establishing a novel research approach to broaden participation in engineering; (4) by employing innovative dissemination techniques that expand the impact of student participant voices; and (5) by contributing to evidence-based foundations for the future development of faculty-centered support structures related to expanding concepts of **diversity** and inclusion. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: CAREER: Fast and Accurate Statistical Learning and Inference from Large-Scale Data: Theory, Methods, and Algorithms

Awardee: University of Pennsylvania

Amount: \$320,000.00

Abstract: this project will develop statistical methods for analyzing large datasets. such massive datasets are emerging as an important challenge in many areas of science, engineering, and business. the research will pursue a multi-pronged approach to addressing several fundamental

questions in the analysis of such datasets, focusing on three key areas. the first one is sketching and random projections, which is a powerful randomized approach to data analysis used when the data must be analyzed on a single machine. the second area is distributed statistical learning and inference, where datasets are spread across multiple locations, with limited communication among them. the third is model retraining, where statistical or machine learning models must be updated efficiently after data has been added or deleted from the original training set. in addition, the project will have a significant educational component, with the pi developing a new course on statistical machine learning. this project will also train a graduate student. the pi is committed to **diversity** and inclusion, including women and underrepresented minorities in all aspects of the project. the methods developed for the project will be made freely available as software, which will allow others to directly use and benefit from the results. in the area of sketching, the project will leverage powerful tools from asymptotic random matrix theory and free probability to analyze fundamental problems, such as regression and clustering. in the area of distributed learning, the pi plans to develop and analyze statistical methods for distributed learning via gradient based optimization. for model retraining, the pi aims to study the connections between retraining and conformal prediction, with the goal of developing improved and broadly applicable methods for predictive inference. on a technical level, the work will involve advanced tools from probability theory, such as random matrix theory, as well as tools from numerical optimization. by carefully analyzing computational aspects of large-scale statistical analysis, the work will aim to bridge gaps between the statistical and computational perspectives. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Boron in soil carbonates: developing a quantitative soil CO<sub>2</sub> proxy

Awardee: William Marsh Rice University

Amount: \$319,659.00

Abstract: rising atmospheric carbon dioxide (CO<sub>2</sub>) levels pose a global challenge. understanding and preparing for the future impacts of rising CO<sub>2</sub> requires us to look into the past at times periods during earth's history when atmospheric CO<sub>2</sub> levels were higher than they are today. this observational approach is crucial to help test and improve models that are used to project scenarios for the future. this project is aimed at improving the ability to quantify atmospheric CO<sub>2</sub> levels of the past. the proposed improvement involves measurements of boron (B) levels and isotopic abundances in calcium carbonate minerals formed in ancient soils. established theory predicts that B in soil carbonates is sensitive to the abundance of CO<sub>2</sub> belowground in soil pore spaces, which is the most uncertain input into an established and longstanding paleo-CO<sub>2</sub> proxy or indicator. this project will test that theoretical predication with laboratory experiments and studies of natural, modern soils. during the course of the project, undergraduate students from groups underrepresented in the sciences will be mentored through a series of established programs including the research traineeship experience and an NSF research experiences for undergraduates project at UT Austin and Rice University. multiple recruiting efforts will also be initiated to help improve diversity in undergraduate geoscience programs, including cooperation with the OnRamps program at UT Austin and with regional magnet schools that have a high ethnic diversity within the student population and/or high percentage of underprivileged students. the chemistry of fossilized soils, or paleosols, can record quantitative information about ancient climates and ecosystems. in particular, the carbonate minerals that form within some modern and ancient soils have been targeted for analysis as they are thought to record the composition of soil water and gas in ways that permit the determination of ancient atmospheric pCO<sub>2</sub> among other variables. however, critical uncertainties in the "traditional" soil carbonate based proxies (e.g., <sup>13</sup>C/<sup>12</sup>C ratios) fundamentally limit understanding of past environments and motivates the development of new proxies --- such as the work on B isotopic ratios (δ<sup>11</sup>B) proposed here -- that provide complementary, but orthogonal constraints on soil chemistry and, potentially, atmospheric CO<sub>2</sub>. the aqueous speciation of B is pH-dependent

and, all else held constant, the pH of soils is a function of soil  $pCO_2$ . So, the  $\delta^{11}B$  of soil carbonates may record information about soil gas that is independent of C isotopic ratios such that, together, they strongly constrain ancient atmospheric compositions and the ecosystem response to C cycle perturbations. As a proof-of-concept, investigators' new measurements of Eocene paleosol carbonates show a decrease in  $B/CA$  and  $\delta^{11}B$  values during the hyperthermal event ETM2. The directionality of these changes are entirely consistent with an increase in soil (and atmospheric)  $CO_2$ . To advance an accurate and quantitative interpretation of these data, they propose to develop new theory for B cycling in soils as well as validate it using experiments and field observations. Critically, their approach will address alternative (to soil  $pCO_2$ ) controls on soil carbonate  $\delta^{11}B$ , such as weathering and biotic cycling, that might confound interpretations of  $CO_2$  change. The proposed work involves microanalytical imaging and analysis of soil carbonates, development and testing of protocols for B isotopic analysis of soil carbonates, soil sorption experiments, precipitation experiments, and the study of B chemistry across soil  $CO_2$  gradients in nature: vertical within individual soils, horizontal across landscapes (climosequence), and temporal (seasonal variation). They will use surface complexation modeling to help interpret experimental and empirical results. The proposed work also involves development of reactive transport models to investigate the effects of biota and weathering on B chemistry in floodplain soils, including the merging of surface complexation models with existing floodplain landscape evolution models. This award reflects NSF's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: OCE-PRF: Understanding substrate mobility as a disturbance in hard rock marine communities

Awardee: University of Washington

Amount: \$319,295.00

Abstract: this award is funded in whole or in part under the American Rescue Plan Act of 2021 (public

law 117-2). human actions impact marine ecosystems in a variety of ways, including shifting wave and current dynamics through global warming and altering the composition of the ocean floor. these changes, in turn, affect the location and distribution of marine communities. for soft-sediment communities, such as sandy beaches, the interaction between fluid forces and sediment disturbance is well understood. this allows scientists to measure sediment mobility and to create detailed predictions of the impact of human activities on these ecosystems. to date there are no measurements analogous to sediment mobility available for marine hard rock ecosystems. this research will investigate a potential measurement system which connects the forces of waves and currents to the resulting erosion of hard rock substrates and will test and evaluate how these disturbance patterns govern the distribution of communities themselves. by developing and testing this substrate mobility metric, this research will open new avenues of investigation for core ecological hypotheses. in addition, this work will allow managers, conservationists, and engineers to better predict the impact of human-generated change on hard rock marine communities. this project will also support the training and education of groups underrepresented in the geosciences through (1) field and data analysis experience via research experiences for undergraduates summer programs, (2) professional development via mentoring relationships between the fellow and undergraduate trainees, and (3) the expansion of their professional network via cross-institutional coordination. disturbance, including fluid forces via waves on rocky shores, is well understood as a community organizing and structuring force. foundational concepts within ecology, such as connell's intermediate disturbance hypothesis and menge and sutherland's competition/predation/disturbance model, recognize that communities exist within a complex mosaic of physical and biological disturbance. this mosaic presents challenges when measuring disturbance regimes since the scales, causes, and consequences of disturbance vary between systems. however, in the marine environment, substrate mobility represents an explicit measure of disturbance impact present across marine ecosystems. this project will determine how to measure substrate mobility on hard substrates through collaboration with usgs geologists. in addition, this

research will investigate a mechanism for disturbance via substrate mobility on benthic organisms through lab experiments and use field surveys to compare patterns of substrate mobility with the distribution of benthic communities and species functional groups. explicitly quantifying the realized movement of hard substrate in response to fluid forcing integrates hard substrates into the already well understood sediment disturbance paradigm. this results in a universal framework of marine disturbance that is potentially revolutionary as it allows for comparative questions spanning a huge **\*\*diversity\*\*** of marine ecosystems, from coral reefs to the abyssal plain. this mechanistic framework provides a new connection between the disciplines of geomorphology and marine ecology. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Applying Student Knowledge for Success in Cybersecurity and Data Science

Awardee: Union County College

Amount: \$318,925.00

Abstract: this project will contribute to the national need for well-educated scientists, mathematicians, engineers, and technicians by supporting the retention and graduation of high-achieving, low-income students with demonstrated financial need at kean university, the new jersey institute of technology, fairleigh dickinson university, brookdale community college, and union county college. in particular, it responds to areas of national need in cybersecurity and data science by increasing the number of students graduating in computer science (cs) and information technology (it). moreover, the project will build regional workforce strength and contribute to the knowledge base on the role of student competence and belonging in ensuring persistence to degree attainment. over its five-year duration, a total of 256 students will benefit, receiving scholarships to complete cs or it degrees. project components include scholarship support for students, undergraduate research and/or professional experience opportunities prior to graduation, and

generation of new knowledge through research on economic realities for students and impact on career trajectories in cybersecurity and data science. students in this program will be prepared to enter the scientific workforce or graduate school as competent, highly trained individuals with a background in teamwork and research. furthermore, they will contribute to increased professional **\*\*diversity\*\*** in the fields of cs and it, and serve as role models to members of their communities.

the students recruited for this program will participate in workshops, take advantage of cohort experiences, and interact closely with faculty who will provide i) academic advising, ii) guidance for navigating higher education and postgraduate opportunities, and iii) supervision of teamwork, research, and working professional experiences. through undergraduate research opportunities and experiences from participation in faculty research programs and/or existing summer research and internship programs, these individual and cohort experiences will provide a basis for overall intellectual growth and promote increased student confidence, retention, and timely degree completion. these academic outcomes are in turn expected to allow students to successfully navigate common attrition points including financial hardship and professional identity development for post-graduate employment and continued education. the project's academic environment includes student-faculty advising and undergraduate research activities, using the affinity research group (arg) model and peer-mentoring. the use of teamwork, collaboration and student-motivated question and answer sessions will positively support research in the field of computer science and information technology regarding educational impact and retention, particularly for minorities, female, and first-generation students. this project is funded by nsf's scholarships in science, technology, engineering, and mathematics program, which seeks to increase the number of low-income academically talented students with demonstrated financial need who earn degrees in stem fields. it also aims to improve the education of future stem workers, and to generate knowledge about academic success, retention, transfer, graduation, and academic/career pathways of low-income students. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review

criteria.

Title: GP-UP: RUI: ENHANCING UNDERREPRESENTED MINORITY PARTICIPATION IN STEM AND THE APPLIED GEOSCIENCES THROUGH INTEGRATED EXPERIENTIAL ACTIVITIES

Awardee: University of Wisconsin-Eau Claire

Amount: \$315,000.00

Abstract: this award is funded in whole or in part under the american rescue plan act of 2021 (public law 117-2). society is facing significant environmental challenges, including climate change, water scarcity and contamination, resource depletion, major changes in global energy production, and the long-term ecological impact of population growth. mitigation of these issues requires a diverse, globally-integrated professional workforce with a strong background in applied geosciences. to meet the need for more geoscientists, the field must broaden its search for future geoscientists by purposefully recruiting individuals from historically excluded groups. the primary objective of this program is to recruit, train and foster career success among individuals from these groups in western wisconsin and minnesota. this program establishes a progressive, multi-phase intentional educational pathway designed to maximize student engagement and retention in the geosciences through high-impact practices, hands-on learning, and dedicated mentorship. the bridge program is a week-long summer institute in applied geoscience based at the university of wisconsin-eau claire that will use inquiry-based activities in the natural setting of the upper midwest to introduce prospective undergraduate students to the relevance of the earth sciences and potential geoscience careers. this program has the potential for long-term, significant enhancement in the \*\*diversity\*\* of the department of geology and the university through the establishment of pipelines between uw-eau claire and regional high schools serving students from historically excluded populations. the proposed pathway entails 1) recruitment of high school juniors into a summer bridge program; 2) matriculation to uw- eau claire; 3) participation in a foundational research experience immediately

prior to their 1st year of college; 4) a college experience characterized by intentional peer and faculty mentoring and high-impact practices, and 5) career development. the project will directly involve at least five department faculty and staff, including an early career female geoscientist, eighteen (18) undergraduate students, and a number of uw-eau claire co-curricular staff over a three-year period. this team will work with ~54 high school students and ~9 high school science teachers from western wisconsin and eastern minnesota during the project. importantly, the strong equity, **\*\*diversity\*\***, and inclusivity framework at uw-eau claire will be leveraged to continue this outreach program beyond the life of the grant. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: GP-UP: Building Opportunities through Networks of Discovery in the Geosciences (GEOBOND)

Awardee: California State University-Fresno Foundation

Amount: \$315,000.00

Abstract: this award is funded in whole or in part under the american rescue plan act of 2021 (public law 117-2). fresno state and the state center community college district serve the agriculturally-rich, ethnically-diverse, and socio-economically disadvantaged san joaquin valley of california, providing critical educational pathways for geoscience majors and careers. this project will strengthen professional networks and streamline student pathways within the san joaquin valley, which has been affected by severe air pollution, drought and water contamination issues, and climate change impacts, all of which disproportionately impact socio-economically disadvantaged communities. pis plan to implement a student support system, along with community-based problem solving curriculum, and undergraduate research experiences that cross institutions. the project aims to increase the number and **\*\*diversity\*\*** of students entering and graduating from undergraduate

geoscience majors in order to support an innovative and committed geoscience workforce that can tackle environmental justice challenges in the san joaquin valley and beyond. building opportunities through networks of discovery in the geosciences (geobond) is a collaboration between fresno state (four year college) and multiple local two-year colleges to create a novel student support system for undergraduate geoscience students that accommodates the various pathways through which they join the program at fresno state: first-time freshmen, change of major, and transfer students. the project involves three-mutually reinforcing activities:1) developing an undergraduate geoscience learning community cohort program that includes a connected sequence of courses, co-curricular professional development activities, and scaffolded research experiences; 2) forming a professional learning community to collaboratively re-design geoscience courses across partner institutions that incorporate environmental justice themes and evidence-based teaching strategies; and 3) establishing a community-based research program to investigate local environmental issues in collaboration with community organizations and geoscience professionals. the proposed project will advance knowledge about which strategies are most effective for recruiting and retaining undergraduate students and creating inclusive environments in the geosciences that are attractive and supportive to students from groups that have been historically excluded in stem. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: GP-GO: Integrating Spatial Literacy into Geoscience: Bridging the gap between education and workforce in the U.S.

Awardee: Bowling Green State University

Amount: \$314,987.00

Abstract: this award is funded in whole or in part under the american rescue plan act of 2021 (public law 117-2). by focusing on recruitment and retention of students from historically excluded

communities, the educational-research program spatial literacy - splitgeoscience provides an effective method of increasing **\*\*diversity\*\*** in geoscience, while strengthening obligations to society and broadening intellectual values in stem research. through a combination of workshops, hands-on training, field experience, and internship placement, the program emphasizes partnerships between academia, industry, and multicultural organizations to connect undergraduate and graduate students to future employers and to the scientific community at large. the program integrates geoscience and geospatial literacy with the socioeconomic needs of local communities across the united states, and thus, contributes to understanding geoscience-related challenges across the nation. the geospatial component of the program supports the urgent demand of the u.s. government and industry to prepare the next generation of skilled geoscientists to handle serious problems, such as the effects and mitigation of natural disasters, that are crucial to national welfare and security. this interactive approach attracts students and sparks their research curiosity and critical thinking. the splitgeoscience program is a three-year program proposed by bowling green state university in collaboration with central state university, the university of louisiana at lafayette, idaho state university, and americaview, a consortium of more than 40 universities. the project leverages innovative hands-on learning and field experience using the most sophisticated satellite- and drone-based technologies, plus internship opportunities, to satisfy two goals: 1) encourage and strengthen the geoscience professional development of students from historically excluded communities and facilitate their school-to-work transition using effective recruitment and retention strategies; and 2) elevate the status of career-related pathways of these students by becoming well-rounded and ready-for-job-market professionals. the program consists of two major components: 1) a series of intensive on-site hands-on learning events allowing insights into real-world geoscience problems using the most recent geospatial techniques learned from experts; and 2) a work placement program for university students established with industry, universities, and government. the ability to process and analyze spatial data to confront pressing geoscience and environmental issues is becoming the fundamental form of literacy for experts in geoscience, which

is a fast-growing interest of government, academia, and industry. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Exploring the interplay between form and function: the force-velocity trade-off in the spider predatory strike.

Awardee: University of Maryland, College Park

Amount: \$314,640.00

Abstract: spiders are important predators of insects and other small animals, and the group has nearly 50,000 described species. they are one of the most diverse and numerous groups of animals and occupy a wide variety of habitats; spiders also play an essential role in controlling pest populations. while great advances have been made in understanding how spiders use silk and venom to capture prey, very little is known about the main feeding structures of spiders, the chelicerae. these in some respects function like jaws of vertebrates since they are used to grasp and process prey. this research focuses on how the chelicerae are used during the predatory strike, when the spider grasps the prey and injects it with venom, and how the shape, speed and strength of chelicerae vary in different groups of spiders. the researchers will compare the anatomy and movements of chelicerae in a wide variety of spiders to better understand the evolution of feeding in the group. this work will also examine details of the super-fast predatory strike, found in certain types of spiders, and determine how it evolved. in addition to revealing the function and evolution of spider chelicerae, the project introduces spider biology to the next generation of scientists, with outreach to several groups ranging from high-school students to postdoctoral scholars. results from this research will also be used to engage and educate the public, including school-aged children, through hands-on lessons that will be displayed at the national museum of natural history and used in a summer day camp at the university of maryland. this research focuses on the comparative

functional morphology of spider chelicerae, and tests the hypothesis that a fundamental biomechanical principle, the force-velocity trade-off, explains the diversification of their morphology and predatory strike dynamics. it is widely assumed that lever-based skeletomuscular systems are optimized to produce either high forces or high velocities, but not both simultaneously. predictions of the force-velocity hypothesis will be tested using a broad sample of species from across the spider tree of life, including the "trap-jaw" spiders, some of which have predatory strikes that are the fastest movements known among arachnids. structural details of the exoskeleton and musculature will be quantified through analysis of computed tomography scans and histological sections, and functional performance variables such as strike velocity will be measured through analysis of high-speed videos. a molecular phylogeny will be generated and used to provide the historical framework for examining the evolution of morphology and strike performance. phylogenetically-informed statistical analyses will be used to determine whether the correlations between form and function anticipated by the force-velocity trade-off are consistent with the biomechanical "diversity" observed in spiders. the results will offer insights into the evolution of form and function in skeletomuscular systems and provide a rich source of new information on spider biology. this award is co-funded by two programs in the directorate for biological sciences, the systematics and bio"diversity" science program in the division of environmental biology, and the physiological mechanisms and biomechanics program in the division of integrative organismal systems. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: GP-UP: Increasing representation and success of African Americans in the geosciences

Awardee: Jackson State University

Amount: \$314,421.00

Abstract: this project is jointly funded by geo golden and the established program to stimulate

competitive research (epscor). careers in the geosciences are expected to grow by 50% above the average job growth rate in the us over the next 10 years, with some subfields experiencing more than double the average growth rate. at the same time undergraduate enrollment within these fields has remained relatively flat or even slightly decreased in recent years, leading to a shortage of trained geoscientists. furthermore, while recent efforts to increase **\*\*diversity\*\*** within stem have been met with success in some fields, **\*\*diversity\*\*** within the geosciences has lagged behind, with geosciences having the lowest levels of inclusion among groups traditionally underrepresented in stem fields; and, among these groups, african americans remain among the least represented making up less than 1.5% of geoscience doctorates awarded in 2018 (national center for science and engineering statistics, survey of earned doctorates). this project aims to increase recruitment, improve long-term student success and persistence, and enhance post-graduate placement of african american students, through increased exposure to potential geoscience careers, multidisciplinary research experiences, skill-building workshops, networking, and faculty-mediated career planning at jackson state university (jsu), the nation's 10th largest historically black college/university. this project will provide a pathway focused on marine science, environmental science, and earth systems science undergraduate degree programs. it aims to increase enrollment, retention, and persistence of urm in the geosciences by: 1) increasing awareness of potential geoscience careers through a robust seminar series, 2) enhancing preparedness through faculty-mediated career planning and application assistance 3) expanding acquisition of relevant experiences through independent research and skill-building workshops. even with focus on a targeted cohort, most of the activities in this program will be open to all jsu students including: 1) a weekly seminar series that will include invited speakers highlighting potential careers and areas of research in the geosciences, 2) a series of workshops focused on building general research skills (e.g., data analysis and visualization, gis/remote sensing, writing research papers) and the generation of professional documents (e.g., curriculum vitae, resume, personal statement, research statement, cover letter) relevant to career advancement, and 3) seminars focused on identifying and

applying for summer research opportunities or internships, as well as post-graduate programs, in the geosciences. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: CAREER: Securing the AI Stack in Autonomous CPS under Physical-Layer Attacks: A Systems Perspective

Awardee: University of California-Irvine

Amount: \$312,787.00

Abstract: recent years have witnessed a massive surge in real-world development and deployment of autonomous cyber-physical systems such as autonomous driving cars and delivery drones/robots. to achieve high-level autonomy in complex environments, the artificial intelligence (ai) stack plays a central role, a type of "brain," which makes them highly security-critical. prior works have studied adversarial attacks against ai algorithms used in autonomous cyber-physical systems, but mostly focus on the ai algorithm-level security properties in complete or partial isolation of the physical context. as these algorithms are only components of the entire system, however, it is both more practically meaningful and effective to study and address their security problems from a systems perspective, especially when under the more general and fundamental physical-layer attack model. this project aims to create a suite of systematic methodologies, solution frameworks, and platforms that can achieve system-level security analysis and defense designs for the ai component of autonomous cyber-physical systems under physical-layer attacks. with the growing deployment and commercialization of autonomous cyber-physical systems in the real world, success in this should directly benefit the safety of everyday lives. this project consists of two research thrusts to cover both the attack and defense sides of the proposed system-level security research. first, to enable system-level security analysis, this project will develop novel system-to-ai and ai-to-system mapping methodologies, by overcoming various design challenges such as systematically

maintaining physical realizability and semantic equivalency in physical-layer attack generation, and effectively accommodating the **\*\*diversity\*\*** of real-world system designs and implementations. second, to develop system-level defense designs, this project will systematically identify and leverage novel design opportunities from both individual system and the operation ecosystem perspectives, including new classes of physical invariants, novel attack-resilient sensor fusion designs leveraging system-level properties, and novel designs that leverage other participants in the operation ecosystem and infrastructure support. this project will also develop a simulation-based evaluation platform with uniform and extensible attack and defense development support, which will be used to facilitate both research and education of autonomous cyber-physical system security. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: REU Site: CAS: Research Experiences for Undergraduates in Sustainable Chemistry and Catalysis at Arizona State University

Awardee: Arizona State University

Amount: \$312,000.00

Abstract: this research experiences for undergraduates (reu) site award to arizona state university, located in tempe, arizona, supports 8 students for 10 weeks of research and professional development during the summers of 2022-2024. in this program, supported by the division of chemistry, participants will have the opportunity to design and apply 'green chemistry' transformations in the fields of organic chemistry, inorganic chemistry, materials chemistry, and biochemistry. the participants will be introduced to leading practices in sustainable chemistry and catalysis, take part in professional development workshops to enhance graduate school and industrial career preparedness. reu students at this site will have the opportunity to network with scientists pursuing a variety of career paths. this project aims to broaden stem participation by

encouraging students to consider how chemical research can lead to positive environmental outcomes. in this reu program, students will participate in individual research projects that focus on sustainable chemistry. topics include the development of new base metal catalysts for coupling and c-h functionalization reactions; the computational screening of environmentally friendly solvents; the use of enzymes for hydrogen evolution and halogenation catalysis; and the development of sustainable methods for the preparation of inorganic materials. notably, these projects will be explored within shared laboratory space, allowing for team-based mentoring and collaboration. workshops on sustainable chemistry research, scientific writing, presentation skills, and networking will be offered alongside team-building activities. project mentors will maintain contact with students through virtual meetings and seminars following conclusion of the program. to increase **\*\*diversity\*\*** within the chemistry workforce, this site also aims to recruit underrepresented students from local community colleges and tribal colleges throughout the southwestern united states. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: OCE-PRF: Determining the depth of fluid infiltration in slow and ultra-slow spread oceanic crust

Awardee: University of Wyoming

Amount: \$310,285.00

Abstract: this award is funded in whole or in part under the american rescue plan act of 2021 (public law 117-2). dr. benjamin urann has been granted an nsf oce prf to work alongside drs. barbara john and j. michael cheadle in the dept of geology & geophysics at the university of wyoming. the goal of this project is to evaluate the depth to which seawater penetrates ocean crust, and whether seawater penetration depth varies with tectonic plate spreading rates across different ocean basins. research products will promote a deeper understanding of earth system processes including

subduction and the interaction between the hydrosphere and deep earth. in addition, this work will help to constrain the habitability of deep ocean crust for microbial life, which relies on delivery of organic and inorganic carbon by circulating hydrothermal fluids. science outreach and education will be a central tenet of the project and involve: (1) outreach with uwyoming office of **\*\*diversity\*\***, equity and inclusion to promote stem and geoscience for underrepresented groups (2) community lectures, both online and in person, including at the wind river indian reservation (3) creation of a uwyoming geological museum exhibit on the generation of ocean crust, hydrothermal vents and the biological **\*\*diversity\*\*** of the seafloor. deep-seated faults expose mantle peridotite and lower crust across broad expanses of seafloor (more than one third of all spreading ridges globally) at slow and ultra-slow spreading ridges. abundant mylonites suggest that these faults must root below regions of earthquake activity, however the depth at which these shear zones initiate remains unknown. these faults act as fluid conduits, yet little is known about the depth to which seawater infiltrates the mantle lithosphere. the pi will investigate the geochemical and textural characteristics of a suite of rock samples from several mid-ocean ridge localities (mid-atlantic, southwest indian, mid-cayman and gakkel ridges) to understand: (1) the depth to which seawater penetrates exposed mantle peridotite along faults, (2) if seawater penetration depth varies with plate spreading rate, (3) the effect of seawater intrusion on global volatile (h<sub>2</sub>o, f, cl, c) cycles and (4) the implications of deep seawater intrusion on the habitability of deep ocean crust. the pi will measure volatile abundances and b isotopes by secondary ion mass spectrometry, in conjunction with petrologic and geochemical thermobarometers and phase equilibria modeling to constrain seawater penetration depths. taken together, this project will provide novel insights into lithosphere-hydrosphere interaction and place some lower bounds on the habitability of the deep lithosphere. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: RI: Medium: Robust Perception through End-User Adaptation

Awardee: Ohio State University

Amount: \$310,000.00

Abstract: for an intelligent system (such as a robot or a self-driving car) to enter end-users' daily lives in a safe and reliable way, the system must generalize beyond the development laboratory to uncontrolled environments where it will be deployed. for instance, a self-driving car may be built and optimized for sunny weather but may be driven by the user in icy or snowy conditions. the state of the art in machine learning and perception cannot generalize or adapt to this sheer **\*\*diversity\*\*** of deployment scenarios. this project seeks to address this challenge by leveraging the fact that people are creatures of habit and tend to use their devices consistently and repeatedly in specific ways (for example, they drive their cars repeatedly over a small set of routes between their home, office, and the marketplace). such repetitive usage provides ample opportunities for the intelligent system to adapt itself to the end-user's specific circumstances, no matter how challenging or different they are. this project builds upon this insight to design robust perceptual systems that will adapt to a diverse array of real-world challenging settings, including self-driving cars in different driving locations and various time and weather conditions. guaranteeing that an intelligent system can operate reliably

across such diverse settings is necessary to unlock the societal benefits that researchers in machine learning, computer vision, and robotics are striving to achieve. beyond the research community, the project will contribute to education by training undergraduate and graduate students and by outreach to high-school students through workshops and summer programs, especially to benefit underrepresented minorities. this research project investigates the design and development of robust perceptual systems through adaptation, by exploiting a specific and well-known property of end-users: humans are creatures of habit and tend to operate devices in specific ways and environments repeatedly and consistently. for example, most people drive their cars primarily along the same routes every day. in particular, the investigators explore three key ideas: (1) adapting the perceptual system by recording sensory input during usage, generating highly reliable pseudo-label annotations that incorporate physical constraints and cross-sensor consistency, and fine-tuning the system while it is offline via dual-task co-adaptation; (2) personalizing the system through repetition, by aligning playbacks over time to leverage deep neural networks' ability to memorize and by augmenting data for diverse settings through label propagation across recordings; (3) verifying adaptation by developing methods to detect and remove noisy labels using learning dynamics and active user verification. these three research aims will be complemented by a comprehensive evaluation plan to include multiple existing self-driving data sets, a newly collected data set by the team of investigators that captures diverse environments along a repeated route, and navigation in home robot scenarios. this research effort towards a much larger, more challenging adaptation problem will open the door to novel solutions in the intersection of computer vision, machine learning, and robotics, including but not limited to reasoning about physics, modeling the relationships between rich perceptual tasks, adapting to changing output distributions, and leveraging patterns in the provenance of the data itself. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Toward lifelike synthetic cells via engineered control of DNA replication

Awardee: Arizona State University

Amount: \$309,665.00

Abstract: the ability of cells to reliably replicate and maintain genomic information is a key facet of life. recapitulating these mechanisms is a critical step towards the development of autonomous synthetic cells that exhibit self-replication and stable propagation of their genetic information. to that end, this project creates a new synthetic mechanism for dna replication control in synthetic cells that will open the door for new applications in biomedicine and biotechnology. this project carries out an integrated social science investigation into the current regulatory framework surrounding engineered synthetic cell technologies. this project also provides educational and technical training aimed at increasing the number and **\*\*diversity\*\*** of undergraduates and graduates pursuing careers in synthetic cell research. public outreach is carried out in conjunction with local partners to increase public awareness of synthetic cell technologies. natural cells have evolved sophisticated mechanisms to control dna replication, to prevent the loss of critical genes while simultaneously preventing runaway replication. analogous replication control mechanisms will be required for synthetic cells. while natural genome replication control systems are complex, plasmids provide a simple yet powerful and modular system for building synthetic replication control systems and modular genomes for synthetic cells. this project addresses the broad challenge of engineering dna replication control mechanisms for synthetic cell systems. rna engineering techniques are used to create modular and programmable synthetic plasmid replication control systems that function in both cells and cell-like systems. this project also studies how dna replication can be utilized for novel biosensing applications. biocontainment applications are investigated through an integrated social science investigation. this award is co-funded by the systems and synthetic biology cluster in the division of molecular and cellular biosciences and the cellular and biochemical engineering program

in the division of chemical, bioengineering, environmental and transport systems. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Digitization TCN: Extending Anthophila research through image and trait digitization (Big-Bee)

Awardee: University of Kansas Center for Research Inc

Amount: \$309,216.00

Abstract: declining populations of bees impact plant-pollinator interactions in both natural and agricultural systems. while bees and other insects pollinate most wild plants, and are critical to sustain a large proportion of global food production, they are decreasing in both numbers and **\*\*diversity\*\***. our understanding of the factors driving these declines is limited because we lack sufficient data on the distribution of bee species, and on the behavioral and anatomical traits that may make them either vulnerable or resilient to human-induced environmental changes, such as habitat loss and climate change. fortunately, wild bees have been collected by researchers and deposited in natural history collections for over 100 years, retaining a wealth of associated attributes that can be extracted from specimen images. this project will digitally capture data and images from these historic specimens, develop tools to measure bee traits from these images, and generate a comprehensive bee trait and image dataset to measure changes through time. this will increase our understanding of specific traits that put bee species at risk of decline - a critical need for both sustaining our agricultural economy and the conservation of our natural resources. in addition, the large image datasets created by this project can be used for new artificial intelligence identification tools that will help improve our future pollinator observation and monitoring efforts. the big-bee thematic collection network (big-bee tcn) will create over one million high-resolution 2d and 3d images of bee specimens, representing over 5,000 worldwide bee species, including all of the major

pollinating species of the united states. the big-bee network includes 13 institutions and partnerships with us government agencies. novel mechanisms for sharing image datasets will be developed and datasets of bee traits will be available through an open data portal, the bee library, for research and education. the big-bee project will engage the general public in research through community science via crowdsourcing trait measurements and data transcription from images. in addition, training and professional development for natural history collection staff, researchers, and university students in data science will be provided through the creation and implementation of workshops focusing on bee traits and species identification. all data resulting from this award will be shared with and publicly available through the national digitized biocollections resource, [idigbio.org](http://idigbio.org). this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: OPP-PRF: Revealing the Genomic Underpinnings of Polar Bear Physiological Adaptations to the Arctic

Awardee: Washington State University

Amount: \$309,112.00

Abstract: study of the genomic basis and evolution of physiological adaptations can provide valuable insight on the impacts of climate change on arctic species. this research focuses on the polar bear, an iconic symbol of climate change, and its adaptation to high-latitude environments. multiple types of genome data from closely related bear species will be used to identify regions of the polar bear genome that underlie specific physiological adaptations. this information will improve understanding of current and future impacts of climate change on these animals. to broaden participation and **\*\*diversity\*\*** in arctic science, the fellow will conduct public outreach, organize workshops, and mentor students from underrepresented groups. while brown and black bears undergo annual hibernation in response to seasonal prey scarcity, the ability to hibernate has been greatly reduced,

and nearly lost altogether, in the adaptation of polar bears to the arctic. given the complexity of the hibernation phenotype and the short divergence time between polar bears and hibernating bear lineages, evolution of regulatory sequences may have played a particularly important role in evolution. through the integration of functional and population genomics datasets, this project will characterize the landscape of protein coding and regulatory evolution in three bear lineages and test the hypothesis that regulatory evolution facilitated the rapid adaptation of the polar bear lineage to arctic environments. this work will advance understanding of the mechanisms and complexity of polar bear adaptations, the processes by which polar bears adapted to arctic environments, and the vulnerability of this apex predator to climate change. the project will also provide insights into vertebrate genomics and evolution, broadening our understanding of the processes by which complex physiological traits arise and evolve in vertebrates. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Assessing Peer Mentorship as a Scalable Intervention to Promote the Academic Success and Retention of Diverse Undergraduate Biology Majors

Awardee: University of California-Irvine

Amount: \$307,764.00

Abstract: this project aims to serve the national interest by improving undergraduate biology student academic success and retention in the major. at most universities in the united states, roughly 50% of undergraduate biology students leave the major within the first two years of their studies. to address this concern, most institutions put in place a number of first-year student support programs. there are, however, considerable challenges and significantly fewer supports for biology students in

their second year of study when the student retention rate is at its lowest. this project seeks to improve the success of second year biology majors by implementing and characterizing near-peer mentorship programs at two research-intensive, minority serving institutions. upper division biology peer mentors who have themselves overcome common barriers to student success will provide academic insights and supports tailored to their second-year biology major mentees. importantly, this project is intended to shed light on the theoretical mechanisms by which peer mentorship promotes mentee academic success. advancing understanding of how peer mentorship works may enable wide adoption and successful implementation of this strategy at a national level across various post-secondary academic settings. in turn, this should increase the number, quality, and **\*\*diversity\*\*** of students graduating with stem degrees. to assess the impact of peer mentorship, this project will employ a rigorous randomized control research design that will enable the assessment of how peer mentorship influences mentee (1) short-term and longer-term academic performance and retention and (2) sense of belonging, academic self-efficacy, and academic habit complexity. additionally, the project will include a focus on identifying and investigating effective near-peer mentorship practices to assess how these behaviors impact mentee outcomes. to assess whether peer mentorship is a scalable intervention at diverse universities, this project will implement peer mentorship programs at two large, public hispanic-serving institutions where both biology programs share similar academic challenges at the second year level. the mentorship structure will include mentee:mentor cohorts in 6:1 ratios, a seminar course where mentees participate in guided discussions on topics relevant to student success, and weekly mentor check-ins. to characterize these mentorship structures and achieve the previously mentioned goals, data will be collected from a variety of sources. institutional research groups at each project site will provide academic grades, major declaration, and demographic data for mentees, while project-generated survey instruments will capture mentee noncognitive impacts and mentor behaviors linked with these outcomes. combined, these data will advance understanding of how peer mentoring promotes student academic success in challenging stem majors. the nsf iuse: ehr program supports research and

development projects to improve the effectiveness of stem education for all students. through the engaged student learning track, the program supports the creation, exploration, and implementation of promising practices and tools. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Sustaining The Utqia?vik Aerosol Record of Decades (STUARD)

Awardee: University of Washington

Amount: \$307,203.00

Abstract: the arctic is warming faster than any other place on earth, with sea ice declining rapidly and sources of sea spray and aerosol emissions derived from living organisms (biogenic) are consequently changing. utqiagvik is at the forefront of this change, abutting one of the largest areas of sea ice loss. these atmospheric aerosols could have far-reaching impacts to both the climate, environment and resident community. because this change has happened largely in the last decade, now is an important time to document changes and continue a data record that will allow for a characterization of the new arctic. the longest and most complete record of airborne fine particles (or ?aerosol?) and their properties in the american arctic is that of utqiagvik, where nsf, the national oceanic and atmospheric administration and the department of energy have contributed to making this unique location serve as a regional record of changes in atmospheric aerosol properties. that record has served as the basis for hundreds of publications on questions from atmospheric chemistry to climate science to ecology and bio\*\*diversity\*\* conservation, which clearly demonstrate the broad, cross-disciplinary scientific value of these measurements. this research will extend the baseline measurements of this arctic aerosol record, including a continuation of the 15-year record of submicron inorganic components, re-instituting the 2-year record of organic components collected a decade ago, enhancing the chemical analysis with sulfur isotopes to improve interpretation of emission sources, continuing particle number size distribution measurements, and re-starting cloud condensation nuclei measurements. re-starting sampling for organic components provides a comparison to that of 2008-2010, documenting the myriad of source changes in the last decade. observations for continuing size distribution records and re-starting cloud condensation nuclei measurements provides the link from the chemical record of sources to the physical impacts on climate and the environment. this project will also allow analysis and archiving of the last 7 years of inorganic filters that were collected and the next 5 years, extending the inorganic aerosol composition record to almost 30 years. in addition to making the data widely available for a breadth

of research, a journalist will publish articles in local news media to broaden the awareness of utqiagvik's historic role as an arctic observatory. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: GP-GO: Growing the number and diversity of non-geoscience undergraduates in Cornell's graduate programs in Atmospheric and Geological Sciences with a Geoscience Learning Ecosystem

Awardee: Cornell University

Amount: \$305,506.00

Abstract: this award is funded in whole or in part under the american rescue plan act of 2021 (public law 117-2). graduate studies in the geosciences require diverse skills and have the potential to attract students from myriad undergraduate majors including chemistry, engineering, computer science, physics, biology, geography, mathematics and the social and behavioral sciences. further, many geoscience graduate programs prepare students for careers in societally relevant fields such as natural hazards, energy, water, and mineral resources, and climate change, that should engage students from these diverse undergraduate majors. however, several studies have shown that student perceptions of careers in the geosciences do not match reality. pis propose to develop a geoscience learning ecosystem that will increase the awareness of geoscience careers in students

from diverse undergraduate majors at the critical juncture between undergraduate and graduate school. We seek to answer the question: which strategies are most effective for increasing the number and **diversity** of non-geoscience undergraduate majors that pursue post-baccalaureate degrees in geoscience? The over-arching goal of the Cornell Geopaths Geoscience Learning Ecosystem (Corggle) program will be to design and test a novel summer bridge program that helps students from non-geoscience fields transition into geoscience graduate programs, specifically giving them exposure to myriad socially relevant careers in the geosciences. The key elements of the project include: (1) engaging diverse undergraduate institutions and students, (2) offering societally relevant summer research projects in geosciences at Cornell, (3) highlighting professional and social development across science, technology, engineering and mathematics fields facilitated by Cornell's award-winning **diversity** programs in engineering, and (4) providing career mentoring. To accomplish the creation of a connected geoscience learning ecosystem, we plan to develop and implement a nine-week summer bridge program, consisting of research and career mentoring for six students per summer from outside the geosciences. A novel aspect of the proposed program is that student research and experiences will span multiple disciplines of high societal relevance, including climate change, natural hazards, and water, energy and mineral resources. By the end of the experience and proposed activities, students will 1) become aware of scientific opportunities in geosciences in areas of high societal relevance, 2) be exposed to multiple career paths, 3) develop a cohort of peers, and 4) will have letters of recommendation from geoscientists that will enhance their chances for successful admission to a graduate program. This award reflects NSF's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: OCE-PRF- Deleterious mutational load in climate driven marine range expansions

Awardee: Northeastern University

Amount: \$304,266.00

Abstract: this award is funded in whole or in part under the american rescue plan act of 2021 (public law 117-2). species range expansions are occurring across the globe at unprecedented rates as global warming continues to accelerate, and even more so in marine species. in general, range expansions occur by a series of colonization events in waves of a few dispersed individuals at a time. this leads to the establishment of a new population that originates from few individuals, resulting in a small non-random representation of the genetic variation from the original population ? a process known as founder effect. as a result of founder effects, a deleterious mutation that arises at the range edge disperses to a newly expanded habitat and can rapidly increase in frequency within the new population (i.e., expansion load), leading to a loss in fitness. this process is enhanced during range expansion due to the small population sizes and low genetic variation present to select against the new mutation. fishing triggers similar evolutionary dynamics of population declines and lower genetic **diversity**, similarly increasing expansion loads. marine species experience faster range expansions than terrestrial species due to their high dispersal ability and are heavily impacted by fishing pressure, yet, the interaction of both these processes have yet to be elucidated in a marine species. quantifying the load of deleterious mutations is critical for conservation and management, because they can limit a population's adaptability and survival. with climate change expected to continue, more species will experience range-shifts at unprecedented rates, making it imperative to document current genetic **diversity** and understand the genetic basis of populations at the forefront of their expanded range. this project will fund the early career development of an nsf ocean sciences postdoctoral fellow and will support the research, training, mentorship, and professional development of the fellow. to enhance the broader impacts and utility of this work, the fellow will disseminate results to the scientific community, the local fishing community and fishery management officials (e.g., noaa, manomet, atlantic states marine fisheries commission). additionally, this project will increase participation of traditionally underrepresented groups in science through: (1) undergraduate student mentorship, (2) outreach seminars for students in local

community colleges, and (3) outreach with the local community. the rapid accumulation of genetic mutations ? and in particular deleterious mutations in edge populations ? remains largely understudied during range expansions. this study presents a unique opportunity to test the evolutionary theory of the accumulation of deleterious mutations in a rapid climate-driven range expansion and harvested marine fish, black sea bass (*centropristis striata*). using a combination of genome-wide data, fitness tests, and quantitative modeling approaches, the following hypotheses will be tested: h1- (higher load at range edge) *c. striata* will show a greater expansion load in coding regions at the range expansion front compared to the historical range center and edge populations; h2- (decreased fitness at range edge) range expanding populations with a greater expansion load will show evidence of decreased fitness-related traits; h3- (load exacerbated by fishing) overfishing will exacerbate the accumulation of deleterious mutational load in expanding populations. if results support the hypotheses (i.e., higher loads and decreased fitness are found at the expanding-front), as predicted by theory, they will have widespread implications for marine conservation strategies in a rapidly changing climate. however, if these hypotheses are rejected, the data will challenge existing scientific assumptions, suggesting marine systems undergo different processes. this integrative dataset will advance understanding of climate-driven range expansions and the interactive effects of climate change and fishing pressure on marine species, such as black sea bass. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Amount: \$303,954.00

Abstract: bees are vitally important to agriculture, food security, and the preservation of natural

ecosystems due to their pollination services. over 85% of the 325,000 flowering plant species on the planet depend on animal pollination and the vast majority is carried out by bees. in the u.s.a. alone bees are responsible for the commercial production of 130 crop plants, generating over \$11 billion in annual revenue. the value of bees to nature and human well-being is abundantly clear. the partnership between bees and flowering plants formed over 100 million years ago, and since that time, bees have radiated globally into an astounding 20,000+ different species, many of which are specialist pollinators of particular plant species or families. the study of bee bio\*\*diversity\*\* is urgently needed because there is growing evidence that some bee species are in decline and baseline knowledge of bee \*\*diversity\*\*, distribution, and family relationships is incomplete. the bees of the world project has the potential to significantly improve knowledge of bee bio\*\*diversity\*\* and to establish a guide to interpret key traits of bees, such as their host-plant associations. by utilizing recent advances in dna sequencing technology, a comprehensive tree-of-life for bees will be generated for the first time, providing a framework from which to study bee \*\*diversity\*\* and their relationships with plants. to disseminate results and general bee knowledge, the project will engage in multiple outreach efforts with professional and non-professional audiences. activities include creation of a virtual bee course, teaching of a molecular methods workshop, and, in collaboration with the natural history museum of utah, development of exhibits and youth education activities focused on pollinators. the project will use cutting edge molecular and analytical methods and engage a global network of collaborators to assemble a comprehensive phylogenomic dataset for bees. the project aims are to: (1) resolve remaining uncertainties in higher-level bee phylogeny and classification, (2) incorporate fossils to reconstruct the global biogeographic history of bees, revealing the origin and spread of bee \*\*diversity\*\* over time, and (3) analyze patterns of host-plant use across bees and for targeted clades at lower taxonomic levels, revealing how host-plant specialization has evolved and impacted rates of diversification in bees. to resolve the phylogeny of bees with improved confidence, the research team will use next-generation dna sequencing approaches and novel laboratory methods to sequence bee species from across the globe. the

project will generate low coverage genomes for most bee genera and ultraconserved element (uce) data for over 3,000 species, filling in sampling gaps. the resulting bee phylogeny will serve as a framework to study bee classification, biogeography, and host-plant evolution. comprehensive databases of bee fossil, distribution, and host-plant information will be created and made available to other researchers. combining results from each component of the project will provide a comprehensive understanding of how bees have diversified and dispersed over time and how their partnership with plants has shaped their evolutionary trajectory. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Equivariant Approaches to Chromatic Homotopy

Awardee: University of California-Los Angeles

Amount: \$302,773.00

Abstract: the project addresses directly the heart of algebraic topology: computing invariants like numbers, groups, and rings to understand spaces. the goal of algebraic topology is to systematically build a connection between algebraic objects like numbers and geometric objects like spaces. this connection allows a two-way flow of information, with algebraic invariants distinguishing spaces and topological methods informing algebraic problems. starting from foundational work of quillen, algebraic and algebraic geometry data like formal groups gives rise to new invariants for spaces with striking properties. this project combines this classical thread with much more recent developments coming from equivariant algebraic topology. "equivariant algebraic topology" remembers a collection of symmetries inherent in a space as part of the data, systematically grouping spaces with the same symmetries, and the numbers and invariants produced must reflect this. this extra structure provides more nuanced computations, giving more information about how the classically described invariants change under symmetries. equivariant algebraic topology has experienced a renaissance recently due to the solution by the pi, hopkins, and ravenel to the kervaire invariant one problem, one of the oldest outstanding problems in algebraic topology. the solution introduced a host of new constructions and techniques that have striking ramifications in classical and equivariant algebraic topology, and this project focuses on unpacking some of these new constructions, exploring their ramifications in classically studied computations, and describing what they mean for algebraic topology in general. many of the projects focus on **diversity** in stem. building on the pi's prior first year seminar on women in math, the pi will create a **diversity**-driven class, combining mathematical content and pedagogy with discussions of representation and inclusion in mathematics. at the same time, the pi intends to create more opportunities for students who do not see themselves as "math people" to connect with algebra and geometry concepts using ucla's

"maker spaces" to have students design and build concrete models. the pi will continue conference organizing, especially conferences focusing on making space for early career mathematicians and for advanced undergraduates, using these as a way to connect students with the ideas and researchers in stable homotopy. using newly developed tools in equivariant stable homotopy, the pi will study the slice spectral sequences for certain chromatically meaningful quotients of hyperreal spectra. these are closely connected to the classical approaches to studying  $k(n)$ -local phenomena using the hopkins--miller higher real k-theory spectra, and at the prime 2, computations here subsume all previously known higher real k-theory computations. the project focuses mainly on concrete computations (both of chromatically meaningful quotients of hyperreal bordism and of more traditional objects like the dual steenrod algebra), while also studying more abstract questions of what kinds of multiplicative structures we can see. finally, an application of all of this machinery to the classical questions of orientability of vector bundles is explored. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: SHF: Small: Programmable Hierarchical Caches: Design, Programming, and Prototyping

Awardee: University of Rochester

Amount: \$301,689.00

Abstract: as computing technology becomes ever more powerful, memory is larger but more complex, with different materials, configurations, and interconnects having different trade-offs among capacity, speed, and cost. because of this complexity, fully automatic solutions are increasingly sub-optimal and brittle. this project develops new designs of the memory hierarchy that are programmable and therefore can achieve better performance and provide stronger guarantees than conventional solutions used on current computer systems ranging from smartphones to

supercomputers. the new programmability enables optimization in software and hardware in concert. since computer cost and speed depend on memory hierarchy, programmable designs can overcome the current limit in scalability and power efficiency. beyond its technical content, the project advances teaching in the science of computer memory and strives to increase the **\*\*diversity\*\*** among participants in this area of research and development. specifically, the project develops a two-level programmable cache system called the lease cache and designs its programming techniques. it has three parts: automatic programming and optimization of the lease cache; hardware design and prototyping of a risc-v processor with the two-level lease cache on an fpga board; and lease-cache theory especially statistical properties and guarantees of the cache performance. through theories and prototyping, the new designs can retain software portability, ensure matching performance to current automatic solutions by default, and provide precisely defined cache performance properties. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: OPUS: Recovery, resilience and the ecology of change

Awardee: University of Colorado at Boulder

Amount: \$301,542.00

Abstract: a diverse ecological community is composed of many species of organisms, all responding to environmental change as well as interacting with each other. in this complex web of nature, predicting how bio**\*\*diversity\*\*** will change over time is challenging. because changes in one species abundance propagate through interactions in the community to affect other species, it is often not sufficient to understand only how organisms respond directly to environmental conditions. this same challenge affects the utilization of monitoring information by conservation and restoration practitioners. considerable time and resources are devoted to monitoring these complex changes,

and it can be difficult to discern whether changes indicate a healthy self-sustaining system or one that is declining and on the verge of collapse. other disciplines outside ecology also deal with analogous complex processes and have developed metrics and analytical frameworks to describe dynamics of multi-dimensional systems over time. in the proposed work, these metrics will be applied to long-term ecological datasets to inform how managers can utilize monitoring datasets. datasets in the proposed synthesis will also form the foundation for graduate student seminars and exchanges to train across subdisciplines and connect theory to applied work. this project seeks to develop a new perspective on the temporal dynamics of multispecies communities by highlighting, through synthesis, ways to describe how complex ecological systems respond to environmental change and how species organization within a community may cause different dynamics in the propagation of environmental change. the project focuses on several innovative metrics that can describe dynamic stability of multispecies communities, using a series of eight long-term plant community datasets. it then seeks to apply new methods that describe the organization of species interactions to connect dynamics with community organization. the last part of the project seeks to make this understanding more useable to decision-makers through collaborations with managers on analyses of long-term conservation monitoring datasets. partnering with managers and training graduate students, the research will explore new ways to arrive at a better understanding of how to monitor and anticipate dynamic ecological responses to environmental change. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Development of an Asymmetric Electrochemical-NHK Reaction using Multivariate Linear Regression Analyses

Awardee: Hunter, Arianne Chenice

Amount: \$300,000.00

Abstract: arianne hunter is awarded a fy21 mathematical and physical sciences ascending postdoctoral research (nsf mps-ascend) fellowship to conduct a program of research and activities related to broadening participation by groups underrepresented in chemistry at cal tech. the project being performed by arianne hunter, entitled development of an asymmetric electrochemical-nhk reaction using multivariate linear regression analyses, is to be conducted under the guidance of mentoring scientist sarah e. reisman. this project is supported by the office of multidisciplinary activities in the mathematical and physical sciences directorate. this project utilizes multivariate linear regression (mlr) models to guide the identification of a privileged ligand class that will transform the electrochemically driven nozaki-hiyama-kishi reaction (e-nhk) into a highly enantioselective method. the specific aims include screening ligands to identify privileged scaffolds that produce high levels of asymmetry, developing tethered ligands to increase the efficiency and asymmetry of the reaction, and conducting electroanalytical investigations into the formation of heteronuclear complexes. these in-depth studies into the e-nhk using data science-driven mlr models and electroanalytical/spectroelectrochemical mechanistic investigations will contribute a new fundamental understanding of the cr and ni speciation in the e-nhk. dr. hunter will also work to broaden participation through efforts like starting a nobcche chapter, participating in the \*\*diversity\*\* in chemistry initiative at caltech, and working with the caltech center for teaching, learning, and outreach. dr. hunter also plans to use her extensive background in organizing scientific community outreach, gained through her non-profit ?we do science too? and her work with ?girltech? of oklahoma city, to organize outreach activities at pasadena high school. this award reflects nsf's

statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Ferroelectricity Emerging from Antisite Defects in Complex Oxides

Awardee: Massachusetts Institute of Technology

Amount: \$300,000.00

Abstract: nontechnical description: ferroelectric materials can store electric charge, and have applications in energy storage, memory devices, and actuators. this project develops a new class of ferroelectric materials that also have magnetic properties. this combination of properties makes them particularly useful for low power memory and computing devices. it has been a challenge to find materials that possess both magnetic and ferroelectric properties at room temperature, but recent work shows a path to this goal by manipulating the composition of a class of oxides that contain iron and a rare earth metal. the change in composition produces a particular type of defect which is the source of the ferroelectricity. this research project investigates ferroelectricity in material compositions that are predicted to show the strongest effects. broader impacts include student training, activities to promote **\*\*diversity\*\***, public outreach via events and online classes, and technology transfer to industrial groups. public outreach is offered at the nano-observatory, an annual event where attendees visit a nanofabrication and characterization lab at mit for demonstrations of nanotechnology, and through free online classes that contribute to a micro-minor certification. outreach to underserved minorities is carried out through a program that brings undergraduates from minority populations to mit, and through a departmental **\*\*diversity\*\***, equity and inclusion collaborative. technical description: ferroelectrics are useful and interesting materials, with applications in energy storage, memory and actuators. furthermore, when combined with ferro- or antiferromagnetic order, the materials are multiferroic and exhibit additional functionality such as voltage-induced changes in magnetization or magnetic field-induced changes

in polarization. this research project explores the hypothesis that ferroelectricity can be induced in perovskites with generic formula  $ABO_3$  as a result of antisite defects, i.e. the presence of one cation on a site that should contain a different cation. recent work has shown that antisite defects in yttrium orthoferrite  $YFeO_3$  with  $y:fe > 1$  lead to a robust room-temperature ferroelectricity, even though the bulk stoichiometric material is non-ferroelectric, and density functional theory predicts that this mechanism would be even stronger in orthoferrites with smaller rare earth cations such as Lu. this research investigates antisite-defect-mediated ferroelectricity in thin films of rare earth-rich orthoferrites  $LuFeO_3$  and  $YbFeO_3$ , and measures the effect of magnetic field on their ferroelectric response. broader impacts include student training, activities to promote **diversity**, public outreach via events and online classes, and technology transfer to industrial groups. public outreach is offered at the nano-observatory, an annual event where attendees visit a nanofabrication and characterization lab at MIT for demonstrations of nanotechnology, and through free online classes that contribute to a micro-minor certification. outreach to underserved minorities is carried out through a program that brings undergraduates from minority populations to MIT, and through a departmental **diversity**, equity and inclusion collaborative. this award reflects NSF's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Observational Studies of Fast Radio Bursts and Technosignatures with the Allen Telescope Array

Awardee: Sheikh, Sofia Zara

Amount: \$300,000.00

Abstract: sofia sheikh is awarded a mathematical and physical sciences ascending postdoctoral research fellowship (mps-ascend) to conduct a program of research and education at the search for extraterrestrial intelligence (seti) institute, mountainview, california. dr. sheikh will improve coherent imaging methods for rejection of radio frequency interference (rfi) and use the improved imaging for characterization of fast radio bursts (frbs). she will work to broaden experience in **\*\*diversity\*\*** and inclusion for underrepresented minority undergraduate students in astronomy. dr. sheikh plans three research activities using the unique qualities of seti's allen telescope array (ata). the first is a hardware and software development project to increase the backend coherent imaging capabilities of the ata. she will use these new capabilities to localize and characterize frbs, which have previously been detected with other radio telescopes. her third goal is searching for signs of extraterrestrial intelligent life by radio observations of the anti-solar point, defining a special space and time on the sky from which a distant observer would see earth in transit of the sun. all three activities rely on implementing novel strategies and pushing into new regions of parameter space (i.e., higher frequencies, new regions of the sky). dr. sheikh seeks to improve the retention rate of

underrepresented scholars in science and engineering fields. her approach is mentoring these students and explicitly teaching the unspoken rules of academic success, helping them build strong professional networks, and provide introductory research experiences. she will enhance existing programs at the seti institute. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: IRES Track I: A U.S.-Ireland Partnership for an International Graduate Research Experience in Biopharmaceutical Processing

Awardee: Thomas Jefferson University

Amount: \$300,000.00

Abstract: the u.s. economy is faced with unprecedented challenges in numerous industry sectors. these challenges underscore a compelling opportunity to prepare the next generation of biopharmaceutical scientists who are specially trained in a field that our world desperately needs. despite the fact that international partnerships between u.s. and non-u.s.-based sites are often challenging to arrange, especially in the area of biomanufacturing, we have a unique opportunity to execute a track 1 international research experience (ires) that capitalizes on our existing collaboration between thomas jefferson university and ireland's national institute for bioprocessing research and training (nibrt), a non-academic research enterprise. the program will provide a unique training and educational research experience in a world class facility, engage underrepresented minorities, and provide assistance to transition the participants to industry or advanced degree programs. thomas jefferson university proposes to engage its international training partner, the national institute for bioprocessing research and training (nibrt) to enable global research in methodologies of bioanalytics and biomonitoring with the following goals: (1) offer a specially selected cohort of students (n=6 each year) the opportunity to develop agile, analytical skills in

biopharmaceutical process engineering with a prominent global leader so that they emerge as distinctively prepared. (2) increase the inclusion of underrepresented minorities (urms) in the life sciences and engineering through participation in biopharmaceutical process engineering and recruitment efforts. (3) train and transition exceptionally prepared, highly competitive students into industry positions or advanced degree programs. our long-term goals are to increase the workforce pipeline for the biopharmaceutical and vaccine industries, and foster u.s. manufacturing competitiveness in an area critically important to human health and national security. the biopharmaceutical industry is highly regulated and research and training opportunities at relevant sites are both difficult and costly. the meaningful relationship already in place between philadelphia/jefferson and nibrt offers a powerful convergence of two thought leaders in establishing a novel and potentially transformative research training experience that capitalizes on our international exchange, existing curriculum, and world-class researchers and capabilities unmatched anywhere else on the globe. furthermore, continued targeted efforts to engage urms are critical to the evolution of the u.s.'s stem workforce as the \*\*diversity\*\* of u.s. populations increase and we attempt to remain competitive in stem fields. finally, we intend to build this nascent international opportunity into a sustainable and long-term exchange in which u.s. and nibrt trainees have global opportunities on either continent. in return, by securing this type of training and experiential learning, we will contribute significantly to a workforce that is desperately needed in the biomanufacturing industry and our findings will bolster the existing literature on the advantages of international stem student training opportunities. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Investigating the Impact of Arts on Student Learning by Introducing Glass Science in the Materials Engineering Curriculum

Awardee: South Dakota School of Mines and Technology

Amount: \$300,000.00

Abstract: this project aims to serve the national interest by improving stem learning environments with a focus on engineering education. a key focus of the project is the introduction of creative glass science elements that enable the creation of a steam (stem + arts)-infused engineering curriculum and co-curriculum. this steam-based project will support the recruitment and retention of engineers and deliver quality science and engineering content to a diverse group of students and to the community. the project hypothesizes that positive student outcomes can be achieved through strategic curricular and co-curricular modifications that integrate and embrace development of steam programs. the project builds on prior research that involves highly successful curricular and co-curricular programming integrating arts into an undergraduate engineering degree program. advances that result from the project have potential to inform and enhance steam teaching within programs in undergraduate engineering. the south dakota school of mines and technology proposes to create a degree program that incorporates glass science into an undergraduate materials engineering degree. the project aims to increase the creativity, innovation, collegiality, entrepreneurship, critical thinking, and intellectual \*\*diversity\*\* of students in the program, and possibly also improve its gender \*\*diversity\*\*. specific aspects of the program include new curriculums in glass science and engineering, integration of steam laboratory and design content with inclusion of content from an embedded artist-in-residence, and formation of a campus steam council. the project's research elements address the sustainability of the proposed modifications through: 1) translation of selected programmatic elements to other campus engineering programs, 2) recruitment of students into the revised degree programs, 3) marketing to the campus, local, and state community, 4) involvement of private-sector partners through steam-influenced design projects, and 5) dissemination to targeted professional societies and associated stakeholders, including local art centers. a rigorous external assessment of the research will be conducted that includes use of herrmann brain dominance inventory and the critical thinking assessment test to

determine the effectiveness of program outcomes. the nsf iuse: ehr program supports research and development projects to improve the effectiveness of stem education for all students. through the engaged student learning track, the program supports the creation, exploration, and implementation of promising practices and tools. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: BPC-DP: Developing Shared Measures Among the BPC Community

Awardee: Computing Research Association

Amount: \$300,000.00

Abstract: the computing community's efforts to broaden participation in computing (bpc) take many different forms but ultimately, these efforts are all working toward the common goals of increasing **\*\*diversity\*\***, equity, and inclusion in the field of computing. measuring the progress of these efforts is critical in improving these activities and assessing their impact. however, such measurement is difficult given the variance of these activities. recognizing the challenges of measuring progress across organizations that engage in a wide variety of activities, this bpc demonstration project will produce common definitions and a framework to enable comparable measurement across the bpc community of practice (including bpc alliances and demonstration projects). these shared frameworks and definitions will facilitate learning across the bpc community about model practices for bpc. development of shared measures is of great interest to all stakeholders, including the bpc alliances and demonstration projects. this project will closely collaborate with the existing bpc alliances to represent the efforts of the bpc community while also maintaining open communication with demonstration projects, new bpc alliances, and others actively working in broadening participation. by providing shared measures for understanding the impact of bpc alliances and other bpc interventions (e.g., demonstration projects), this project will benefit efforts to increase all

underrepresented groups these efforts are intending to support. these include groups identified as underrepresented in computing by nsf (i.e., women, persons with disabilities, blacks and african americans, hispanics, american indians, alaska natives, native hawaiians, and pacific islanders) as well as others who are disadvantaged based on other identities (e.g., sexual orientation) and factors such as socio-economic background. this project will result in a number of tools and resources to help sustain these efforts long-term. the outcomes of this project will add to our knowledge of collective impact measurement in a way that reflects the cumulative experiences of organizations who have been engaged in bpc for more than a decade. this project will enable knowledge exchange and assist in capacity building across bpc alliances by strengthening the connections and collaboration among the alliances and, therefore, expanding their potential for impact. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: ASCEND: Expanding the Multi-Messenger Impact of In-Ice Radio Experiments

Awardee: Muzio, Marco Stein

Amount: \$300,000.00

Abstract: marco muzio is awarded an nsf mathematical and physical sciences ascending postdoctoral research fellowship to conduct a program of research and education at the pennsylvania state university. muzio will use multi-messenger astronomy, combining neutrino, gamma-ray, and particle detection to study the highest energy events. specifically, muzio will use data from the askaryan radio array (ara) to perform new, higher sensitivity studies related to very high-energy (vhe) neutrinos above approximately 10 petaelectronvolts. along with the research, muzio will work with the climate and \*\*diversity\*\* committee and others at the university to broaden the participation of underrepresented minorities at both the postdoctoral and undergraduate levels.

detection of vhe neutrinos will address pressing questions in the study of ultrahigh energy cosmic

rays, including how their sources are distributed, what their composition is, and if accelerators produce a substantial flux at energies at length scales inaccessible through cosmic ray observations. importantly, neutrinos will address these questions in a hadronic interaction model-independent way, sidestepping particle physics uncertainties that plague the interpretation of cosmic ray data. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: BPC-DP: Distributed REsearch Apprenticeships for Master?s (DREAM)

Awardee: Colorado School of Mines

Amount: \$300,000.00

Abstract: people who identify as female, black/african american, hispanic/latino, native american, hawaiian, alaskan, asian pacific islander, and people with disabilities have been traditionally marginalized in the computing and tech fields. to reverse this trend and attract more students from these populations to the field, the 13 universities in the mscs pathways to computing consortium created ?bridge to an ms in computer science? programs for students with non-cs bachelor?s degrees. the primary goal of the distributed research apprenticeships for master?s (dream) project is to increase the number of students pursuing a ph.d. in cs from the groups mentioned previously and, ultimately, increase the **\*\*diversity\*\*** of the computing professoriate. dream is modeled after the computing research association?s committee on widening participation?s (cra-wp) distributed research experiences for undergraduates (dreu) program, which has been very successful at encouraging diverse undergraduate students to enroll in cs graduate programs. dream funds consortium students from diverse backgrounds to participate in a research experience during their m.s. degree program. in this cohort model, students participate in a robust mentoring program, various community building and networking opportunities, guided research, professional

development, and have opportunities to attend technical conferences. at the end of their research experience, students will begin to see themselves as researchers in computing and be inspired to pursue further research through a ph.d. the diverse demographics of the consortium programs provide a unique opportunity to recruit ph.d. students from a previously untapped population of students. beyond the immediate impact on the cohort of participating students, dream creates a pathway to a ph.d. for students traditionally marginalized away from the computing field that can be scaled nationally. the project team is working in close collaboration with cra-wp to ensure a smooth handoff of the program at the conclusion of the pilot implementation. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: BPC-DP: Distributed REsearch Apprenticeships for Master?s (DREAM)

Awardee: Colorado School of Mines

Amount: \$300,000.00

Abstract: people who identify as female, black/african american, hispanic/latino, native american, hawaiian, alaskan, asian pacific islander, and people with disabilities have been traditionally marginalized in the computing and tech fields. to reverse this trend and attract more students from these populations to the field, the 13 universities in the mscs pathways to computing consortium created ?bridge to an ms in computer science? programs for students with non-cs bachelor?s degrees. the primary goal of the distributed research apprenticeships for master?s (dream) project is to increase the number of students pursuing a ph.d. in cs from the groups mentioned previously and, ultimately, increase the **\*\*diversity\*\*** of the computing professoriate. dream is modeled after the computing research association?s committee on widening participation?s (cra-wp) distributed research experiences for undergraduates (dreu) program, which has been very successful at encouraging diverse undergraduate students to enroll in cs graduate programs. dream funds

consortium students from diverse backgrounds to participate in a research experience during their m.s. degree program. in this cohort model, students participate in a robust mentoring program, various community building and networking opportunities, guided research, professional development, and have opportunities to attend technical conferences. at the end of their research experience, students will begin to see themselves as researchers in computing and be inspired to pursue further research through a ph.d. the diverse demographics of the consortium programs provide a unique opportunity to recruit ph.d. students from a previously untapped population of students. beyond the immediate impact on the cohort of participating students, dream creates a pathway to a ph.d. for students traditionally marginalized away from the computing field that can be scaled nationally. the project team is working in close collaboration with cra-wp to ensure a smooth handoff of the program at the conclusion of the pilot implementation. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: SEE DATA: Spaces of Empowerment for Equity and Diversity: Advancement Through Access

Awardee: Portland State University

Amount: \$300,000.00

Abstract: the spaces of empowerment for equity and **\*\*diversity\*\***: advancement through access (see-data) project at portland state university (psu) aims to identify, understand, and improve the workplace experiences and retention of faculty in stem fields who have been traditionally minoritized and marginalized based on gender, race/ethnicity, and other intersectional identities (e.g., sexual orientation, disability, socioeconomic status, national origin, immigrant status). the project will collect, analyze, and map data about faculty's experiences at psu to inform programs and policies that seek to foster the retention and flourishing of a faculty that more closely resembles the diverse student body at psu. it is anticipated that the see-data project will significantly contribute to

improving institutional equity. see-data will take an intersectional approach to data collection, management, analysis, visualization, and dissemination by combining qualitative, quantitative, and socio-spatial data, techniques, and mapping tools with the goal of conveying more nuanced understandings of the equity landscape and "ecosystem" for diverse faculty members than has been established to date elsewhere. the scope of the methodology that the project will develop will be applicable to stem departments across the university and to other institutions. the project's strengths-based self-assessment methodologies will contribute to a toolkit for capturing and visualizing the dynamic interplay between the multiple lived identities of stem faculty as they are manifested in the institutional landscape, thus supporting advance goals for expanding intersectional equity strategies and interventions. this project addresses limits in extant sources of data (e.g., numerical counts, climate surveys) on the intersectional factors affecting academic stem recruitment, workplace experiences, retention, and promotion. outcomes will be expected to advance a clearer and deeper understanding of individual empowerment pathways and institutional systemic change levers in advancing faculty equity in stem. knowledge generated will be disseminated via avenues such as a project webpage, public seminars, and conferences geared to professional and general audiences, as well as through networks within psu, at other colleges/universities, with professional organizations nationally, and via the advance resource coordination network (arc) and strategic website. the nsf advance program is designed to foster gender equity through a focus on the identification and elimination of organizational barriers that impede the full participation and advancement of diverse faculty in academic institutions. organizational barriers that inhibit equity may exist in policies, processes, practices, and the organizational culture and climate. advance "catalyst" awards provide support for institutional equity assessments and the development of five-year faculty equity strategic plans at an academic, non-profit institution of higher education. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Probing Undiscovered Reaction Pathways in the Decomposition of Highly Energized Molecules: Isomerization, Roaming, and Proton Coupled Electron Transfer

Awardee: Marquette University

Amount: \$300,000.00

Abstract: with support from the chemical structure, dynamics, and mechanisms-a (csdm-a) program in the division of chemistry, professors scott reid at marquette university and richard loomis at washington university in st. louis, respectively, will explore competing bimolecular reaction pathways of highly-excited molecules. energized reactant molecules can relax via multiple mechanisms, including (i) direct bimolecular reactions, (ii) isomerization (changes in molecular structure and connectivity), (iii) roaming (long-range intermolecular interactions that lead to unexpected, secondary products), and proton-coupled electron transfer (pcet) reactions that occur following the initial transfer of an electron or proton from an excited reactant molecule to the other reactant molecule. the understanding of roaming, isomerization, and pcet processes are still at an elementary stage. reid and loomis hypothesize the pathways that compete with direct bimolecular reactions are central to many fundamental processes, and they are striving to develop a unified understanding of the factors that dictate their efficiencies and how these pathways dictate the properties of the products. thus, the research teams led by professors reid and loomis are using a powerful combination of frequency- and time-resolved experiments, together with theory, to unravel the dynamics of these processes. the experiments will be performed in vacuum, in solvents, and in solid matrices, and the energetics and yields of the products are characterized as a function of how much energy is deposited into the reacting molecules. in this manner, the research teams will characterize how these different pathways and their efficiencies are altered by local environment and excitation. the collaborative nature of the research project offers graduate and undergraduate students training in an array of important skill areas, preparing them for careers in science. the

project also has a focus on broadening the participation of underrepresented groups in science, technology, engineering, and mathematics (stem) through a number of complementary initiatives at marquette and washington university. a notable component of this program is the development of highly practical courses for at-risk students at the onset of their graduate education. the courses build on a principle of enhancing **\*\*diversity\*\*** in stem, especially in academia, by providing promising scientists with the tools they need to succeed at an early stage. the goal of this collaborative research project led by professors scott reid and richard loomis at marquette university and washington university in st. louis, respectively, is the characterization of common features associated with isomerization, roaming, and pcet reactions on ground, excited, and ion radical surfaces. the systems being explored fall into two categories: (i) reaction dynamics of halons including the isomers of di-bromoethane, di-chloroethane, and haloethane and their partially deuterated analogs, and (ii) reactions of ionized complexes of ammonia with halobenzenes. these target systems, the halons, are environmentally important, are expected to demonstrate the full range of reaction pathways listed above, and yet are small enough to be tractable via high-level theoretical methods. the complementary and overlapping skill sets and techniques in the two laboratories enable experiments to be undertaken with high sensitivity, energy resolution, and temporal resolution. specifically, frequency-resolved fluorescence-based spectroscopy, frequency- and time-resolved ion time-of-flight velocity mapped imaging experiments, ultrafast transient absorption spectroscopy, and infrared excitation experiments will be pursued. these reaction systems were chosen, in part, because of the ability to probe the properties of the parent molecules or complexes and all of the product channels with high sensitivity. the selected systems are also being investigated in detail using computational methods, with the experimental results providing stringent tests and milestones for ongoing development of the theory. important challenges in this research effort include state-specific preparation of the reactants and state-resolved detection of the products, challenges that are to be overcome through the combined effort of the two research groups. student training opportunities and an emphasis on broadening participation in stem

education and research further broaden the impacts of the project. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Testing the reduction of aerobic habitat as a common kill mechanism for major mass extinction events

Awardee: University of Chicago

Amount: \$300,000.00

Abstract: the project will study the response of marine animal ecosystems to environmental change using three mass extinction events from the geological record as study systems. specifically, the project will test the hypothesis that a large proportion of extinction during these events can be explained by the stresses that elevated temperatures and reduced oxygen availability place on animal respiration. geochemical data will be used to constrain computer simulations of changing ocean conditions during these mass extinction events. results from laboratory studies on animal respiration will then be paired with fossil data to assess whether differences in extinction intensity in space and across taxonomic groups can be explained by spatial variation in environmental change or differences among taxonomic groups in their ability to withstand environmental change. the project will provide interdisciplinary training to a group of graduate students and post-docs. it will further impact stem education through the creation of a website that will allow access to model results so that students can visualize and explore model output to understand cause-effect relationships between continental configuration, ocean conditions, and biological **\*\*diversity\*\***. the investigators will also offer short-courses on earth system modeling and data interpretation at major conferences that will be recorded for asynchronous use. the project will also involve the development of a podcast series addressing how we reconstruct the ancient earth system and use these reconstructions to better understand the present and predict the future. in this project, the

hypothesis will be tested that the loss of habitat through constraints on aerobic respiration under climate change and ocean deoxygenation can explain the magnitude, taxonomic selectivity, and latitude variation in intensity for the late devonian (frasnian-fammenian), end-permian, and end-triassic mass extinction events. paleoredox and paleoclimate proxy data and geochemical indicators of diagenetic alteration will be used for both global average and local conditions before and after each major event combined with predictions from earth system models and occurrence data from the fossil record of marine animals to separate aspects of extinction that can be explained by physiological stress from those that require other explanations. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: IRES Track I: Manifestations of climate change in extreme events

Awardee: Pennsylvania State Univ University Park

Amount: \$300,000.00

Abstract: human-induced changes in the global climate and atmospheric environment are among the most significant scientific challenges to address this century. increasing concentrations of greenhouse gases are the dominant cause of observed warming since the mid-20th century. earth system models are used to both understand these issues as well as project the future state of the

climate and the environment. however, significant uncertainties remain in these models, owing to the lack of high-quality data of key variables, especially from complex terrains that encompass mountains, rainforests, and a variety of land uses. this ires project will provide five u.s. undergraduate students each year the opportunity to spend eight weeks in peru to study the extreme weather manifestations of climate change. peru is on the extreme side of potential impacts that climate change can have, and therefore, the training we will develop in peru could be applied to the united states. students will learn the necessary research skills to apply theories about climate change, impacts, adaptation, and solutions within the peruvian context. students will also work in peru to address challenges associated with climate change. the international experiences will contribute to increasing retention and graduation rates of participating students, improve programs and strategies for sustaining **\*\*diversity\*\*** in science and engineering. the program provides individually challenging experiences in research and well-organized integrative team activities and professional development to undergraduate students. the program aims to provide a high quality, and balanced research activities that positively impact the participants' lifelong career choices in science and engineering research. the students will work with faculty and investigators from peru and united states to integrate weather sensors and mount them on a drone, design experiments, collect and analyze data, and present results to scientific and non-scientific audiences. students will study complex terrain and ecosystems in collaboration with local scientific and engineering experts, and utilize laboratory and local field infrastructure. proposed activities rely on existing and new data sets, social science data collection, and ground-based and remote sensing measurements in collaboration with local partners in peru to study extreme weather events such as severe hailstorms and frost conditions in the peruvian andes, and wildfires in the peruvian amazon. research activities will include data analyses to mitigate el niño phenomena and identify drawdown solutions to combat climate change. students will work within the areas of faculty expertise but choose and define a project of personal interest. each project will have at least two faculty mentors to help the students develop with multidisciplinary approaches to tackle their research activities. this program includes a

robust mentoring component aimed at sharing best practices for future researchers. the involvement of undergraduates in research with exposure to climate change and the social impact on humankind has implications well beyond the technical scope of the individual research projects, and the inclusion of science communication shows how research can directly impact society. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: FET: Medium: Robust Quantum Networks via Efficient Entanglement Distribution

Awardee: CUNY Hunter College

Amount: \$300,000.00

Abstract: quantum computing has the potential, if realized, to significantly alter the computing landscape. however, building large-scale quantum computers is a key challenge. quantum networks (qns) enable the construction of large, robust, and more capable quantum-computing platforms by connecting smaller quantum computers. networked quantum systems have the potential to significantly alter various activities in society by leading to faster development in medicine and engineering; more secure and privacy-preserving communication; and hitherto infeasible optimizations that leverage the immense computational power to identify efficiencies in manufacturing, logistics, finance, etc. this project is also using the potential and attractiveness of qns to design and offer a variety of educational programs, including a flexible post-baccalaureate program in quantum computing and networking to cater to non-traditional students, improve the **\*\*diversity\*\*** of undergraduate and graduate student body, and develop a quantum capable workforce. building qns that support robust communication across nodes requires several fundamental scientific and technological advances, especially since classical techniques cannot be directly used in the quantum regime. qns can be used to build quantum computing systems that are

more capable and more resilient than stand-alone quantum computers. this project is examining the design and implementation of qns from the ground up by developing an infrastructure for efficient communication and management of quantum entanglements in the network. in addition, the project is addressing specific challenges in two key applications of qns: (i) distributed quantum algorithms, and (ii) quantum sensor networks. the project is evaluating the developed techniques using large-scale simulations and over a 6-node qn testbed spread across long island, ny. the testbed is providing a high-fidelity platform to evaluate the effectiveness of our developed techniques. overall, the project has three research thrusts. in the first thrust, the project is developing an infrastructure to facilitate efficient communication and entanglement management. in particular, it is developing optimization techniques for (i) efficient generation of long-distance entanglement using multiple paths, and (ii) efficient distribution of pre-distributed entanglements. in addition, the project is developing efficient entanglement-distillation strategies in practical settings, and protocols for multicast primitives. in the second thrust, the project is addressing challenges in the context of two key qn applications to corroborate and validate the developed techniques. in particular, the project is developing optimization techniques for efficient distributed implementation of centralized quantum circuits; efficient distributed implementations are important for qn's computational success. in the context of quantum sensor networks, it is designing efficient protocols for the estimation of binary parameter functions and investigating the benefit of entanglements in these settings. in the third thrust, the project is evaluating the above techniques using large-scale simulations and a small qn testbed. to evaluate qn performance effectively, the project is formulating novel performance metrics for qns; this requires non-trivial generalization of the classical network metrics. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Radiation Transport in Strongly Coupled High-Energy-Density Plasmas

Awardee: LeFevre, Heath Joseph

Amount: \$300,000.00

Abstract: heath lefevre is awarded an nsf mathematical and physical sciences ascending postdoctoral research fellowship to conduct a program of research and education at the university of michigan ? ann arbor. lefevre will study high-energy density (hed) plasmas at the omega and omega ep laser facilities at the university of rochester. the project aims to understand and measure coupling between intense electromagnetic radiation and an hed plasma, a plasma with particularly high particle density and temperature. the regime where effects of strong coupling on emission and absorption of radiation in hed plasmas is not well studied and is important to the physics of white dwarf stars and type ia supernova, as well as for inertial confinement fusion plasmas. along with the research, lefevre will conduct outreach, recruiting, and mentoring efforts aimed at increasing the

**\*\*diversity\*\*** of students studying plasma physics. this study explores strongly coupled, radiation flux dominated plasmas, which are relevant to inertial confinement fusion, white dwarf stars, and type ia supernova. this is a physics regime that is difficult to model and therefore the experimental results to be obtained at the university of rochester's high energy laser facilities are of fundamental interest to astrophysics and hed science research. comparing results of these experiments with available radiation hydrodynamics, atomic kinetics, and radiation transport codes will quantify the effects of radiation coupling in these plasmas. this study will be able to eliminate common sources of uncertainty and error in hed physics models due to its use of multiple facilities and experimental conditions. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: DMS-EPSRC Eco-Evolutionary Dynamics of Fluctuating Populations

Awardee: Virginia Polytechnic Institute and State University

Amount: \$300,000.00

Abstract: a fundamental scientific puzzle is understanding the origin of **\*\*diversity\*\*** and the evolution of cooperation, which can be understood through understanding the stability of populations composed of competing species. it directly addresses deep societal concerns, such as the maintenance of endangered ecologies, the effective prevention of the loss of bio**\*\*diversity\*\***, and stemming the rise of antimicrobial resistance. to this end, one must address the coupled eco-evolutionary dynamics of fluctuating populations, namely the interdependence and combined effects of (i) random internal variability in population numbers, composition, and each species' traits and (ii) sudden, gradual, or repetitive external changes in environmental conditions on the evolution of an ecological system. this transdisciplinary research is situated at the interface of biology, mathematics, physics, statistics, and computer science and will combine a set of advanced theoretical and mathematical tools from these fields that so far have rarely been utilized together. it

will be pursued in an international collaboration, funded jointly through national science foundation ? division of mathematical sciences and the u.k. engineering and physical sciences research council, and provide advanced training for a postdoctoral research fellow at the university of leeds and a graduate student at virginia tech. conceptual and technical advances in the basic understanding of complex interacting systems in general, and specifically of spontaneous pattern formation under the combined influence of intrinsic noise and environmental variability, are anticipated, and will be disseminated to the scientific community at tailored workshops to be organized alternatingly at leeds, u.k. and blacksburg, virginia. while population dynamics traditionally ignores fluctuations and considers static and homogeneous environments, demographic noise arising from randomly occurring birth or death events as well as external environmental variations play a crucial role in understanding the eco-evolutionary dynamics of a population in time. the interdependence of external environmental variability and internal demographic noise is poorly understood to date, but it is of eminent importance, for example in microbial communities, which are often subject to sudden and extreme environmental changes. in particular, modelling populations of varying size and composition subject to changing external factors is crucial to gain a full understanding of the evolution of microbial antibiotic resistance. standard theoretical techniques, like mean-field approximations or system-size expansions cannot be straightforwardly used, and new mathematical approaches are needed. a suite of novel theoretical methods, based on and combining evolutionary and nonlinear dynamics, deterministic and stochastic partial differential equations, agent-based computer simulations, and tools from non-equilibrium statistical physics such as dynamical scaling theory, renormalization group approaches to critical phenomena, and mathematical representations of stochastic kinetics in terms of continuum field theories, will be developed. the goal is to design and quantitatively characterize biologically relevant evolutionary models of increasing levels of complexity, which incorporate both switching environmental features and fully account for the underlying stochasticity. these theoretical advances will be utilized to generate directly testable predictions for laboratory experiments to further explore how demographic noise and environmental

variability conjointly influence the emergence of collective features and affect species coexistence and their organization into spatial patterns. this project is jointly funded by the mps division of mathematical sciences (dms) through the mathematical biology program and the ls-biotech venture fund, and the division of materials research (dmr) through the condensed matter and materials theory program. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Catalyzing STEM Gender Equity at Drexel: Building a Foundation for Systemic Transformation

Awardee: Drexel University

Amount: \$300,000.00

Abstract: it is fundamentally important to ensure **\*\*diversity\*\*** and equity across the career lifespan of faculty in science, technology, engineering, and mathematics (stem). motivated by this core tenant and priority for drexel university, the long-term goal for this project team is to create a pipeline of outstanding, diverse women leaders at drexel. however, this can only be accomplished through the retention and promotion of women faculty at the institution. drexel has a long history of recruiting talented women faculty at the assistant professor level, who are then promoted to associate professor. however, a recent internal audit identified a consistent and persistent gap in promotion to full. the gap is particularly stark for underrepresented minority women. this study is designed to evaluate the current policies, procedures, and practices at drexel for faculty transitioning from associate to full professor, identify best practices developed through other advance programs, and to use this insight to develop an evidence-based fair and equitable promotion policies, procedures, and practices for use campus-wide. recognizing the need to eliminate systemic gender and race barriers impeding progress across the academic lifespan, this project will focus on the intersections of gender and race/ethnicity, while also paying attention to gender identity and expression, country

of origin, different abilities, family status, and faculty appointment type and rank. Drexel prioritizes **diversity** and equity for university leadership. This project aims to develop a transparent and sustainable professional "roadmap" to professor, which is essential for attaining gender parity and **diversity** at that rank. The three goals of this project are: 1) understand the policies, procedures, and practices that negatively impact or facilitate women's retention and promotion to full professor; 2) identify best-practice strategies developed by other advanced institutions that might be tailored to fit Drexel's context; and 3) utilize findings to create a comprehensive strategic action plan for developing inclusive and diverse leadership at Drexel University. This two-year mixed-method study will prepare Drexel for future data collection and data analyses of faculty equity which can be used by institutional leadership to inform decision-making. The advance "catalyst" work will also prepare the institution to implement evidence-based strategies to enhance retention and promotion for all faculty which will be outlined in a five-year faculty equity strategic plan that will be produced as part of this project. Results will be disseminated via conferences, peer-review publications, industry press, popular media, and shared with other advanced institutions. The NSF Advance program is designed to foster gender equity through a focus on the identification and elimination of organizational barriers that impede the full participation and advancement of diverse faculty in academic institutions. Organizational barriers that inhibit equity may exist in policies, processes, practices, and the organizational culture and climate. Advance "catalyst" awards provide support for institutional equity assessments and the development of five-year faculty equity strategic plans at an academic, non-profit institution of higher education. This award reflects NSF's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Understanding the Role of Undergraduate Research and Mentoring in the Self-Efficacy, Identity, and Success of Engineering Undergraduate Students

Awardee: University of Memphis

Amount: \$299,998.00

Abstract: this project aims to serve the national interest by improving academic success and broadening participation for engineering students at the university of memphis. it has been shown that engineering identity and self-efficacy play a role in student retention and graduation rates. this study will examine the impact of mentoring and undergraduate research on developing students' engineering identity and self-efficacy. an important aspect of the project is understanding how the proposed interventions in research and mentoring can aid college students who may not see themselves as "fitting in" with engineering as a means of broadening participation. this project will increase the use of undergraduate research as part of the curriculum, make research experiences accessible for all students, and promote broadening participation in engineering. the project team will adapt, implement, research, and evaluate a targeted active learning focused undergraduate research experience for which students will receive course credits towards their baccalaureate engineering degree. using peer and faculty mentoring, students who begin research as early as their first year in college will continue in research and mentoring throughout their time as undergraduate students. it is expected that these interventions will help improve academic success and persistence as well as broaden participation in the engineering workforce. the project goals are to improve academic success, retention, **\*\*diversity\*\***, and inclusion in engineering at the university of memphis by integrating educational interventions such as active learning through project-based research opportunities and peer mentoring that involves networking and role modeling. the educational interventions are designed to foster the development of engineering identity and self-efficacy in undergraduate students. project activities that aim to foster an inclusive culture in engineering include research training units, innovation seminars, and mentoring. the successful implementation of this project is expected to increase awareness and interest in engineering majors and provide a new approach to recruiting students to engineering. important outcomes of the project will be: 1) improving retention of all students in engineering; 2) making engineering majors at the university of

memphis more accessible to undecided freshmen, particularly for the purpose of broadening participation; and 3) supporting engineering identity growth, self-efficacy, and a sense of belonging for undergraduate engineering students. though other projects have investigated some of the components addressed in this project, few have looked at them collectively, as this project will do. as such, this project will generate new knowledge in how to recruit, retain, and broaden participation in undergraduate engineering. in addition, memphis area community college students and high school students will engage in research and mentoring through a one-day summer summit. the adapted undergraduate research and mentoring model will be disseminated through an established consortium and to other interested institutions. project results will be disseminated through conference presentations and journal publications as well as through a dedicated website. the nsf iuse: ehr program supports research and development projects to improve the effectiveness of stem education for all students. through the engaged student learning track, the program supports the creation, exploration, and implementation of promising practices and tools. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: EAGER: ADAPT: AI Guided Design and Synthesis of Semiconducting Molecules

Awardee: Trustees of Boston University

Amount: \$299,995.00

Abstract: understanding how atoms and molecules combine to form more complex molecules and materials is fundamental to chemistry. yet, there are more ways that atoms can be arranged into molecules than there are actual atoms in the universe. chemists typically rely on experience, literature accounts, and ad hoc criteria for designing and prioritizing molecules for specific applications, often resulting in a monumental effort. furthermore, when considering the synthesis of new molecules using tried or untried reactions, chemists must often speculate, relying on instinct

rather than ground truths. the pis will apply and extend several aspects of artificial intelligence (ai) to develop a general platform that will facilitate data-driven property prediction and synthesis of semiconducting materials, focusing on blue light-emitting materials. as a result, this project will expedite the discovery of novel organic semiconductors that can be synthesized efficiently, with optimized properties for target applications. the inclusion of a diverse team of graduate students in this work from the pis? research groups will broaden participation and help create an ai-aware workforce in the context of chemistry and materials science. the research focus will be on optimizing the design of blue light-emitting materials using ai. to carry out this objective, the project will proceed with two parallel experimental tracks connected by an ai platform. in the first track, data and computational models will be used to train ai machine learning and experimental design modules for molecular-pair inputs. this will provide a workflow that is fully containerized, enabling the design of robust blue light-emitting molecules. in the second track, the focus will be on extending the potential chemical space that can be integrated into the first track design concept. this will dramatically increase the **\*\*diversity\*\*** of semiconducting materials that can be explored and provide a roadmap for how to make new, unexplored molecular frameworks with desired properties. the project will incorporate concepts and techniques from high-dimensional sparse regression, machine learning with graph inputs, and discrete optimization. the resulting dual mode platform (property design/synthesis design) will provide an unprecedented level of prediction, making the design and manufacturing of materials a more efficient and automated process. at the same time, novel statistical machine learning and experimental design algorithms are expected to emerge in addressing chemistry problems involving molecular pairs as inputs. this project also provides new opportunities for undergraduate and graduate student training in materials and computational chemistry. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Testing the Effectiveness of a Digital Tool, Tandem, in Assessing and Supporting Inclusive and Equitable Teamwork in Engineering

Awardee: Regents of the University of Michigan - Ann Arbor

Amount: \$299,983.00

Abstract: this project aims to serve the national interest by improving how teamwork in introductory engineering courses is assessed and supported, with specific focus on equity and inclusion. learning how to work effectively in a team is clearly an important goal for preparing undergraduate engineering students. however, supporting inclusive teamwork remains challenging. marginalization on teams has been linked to aspects of students' social identity, such as identifying as a woman or person of color. it can take a variety of forms, including ideas going unheard or being pushed into more menial tasks. particularly in introductory courses and at large colleges and universities, engineering instructors face the additional hurdle of having many students and student teams. with these compounding factors, it is difficult for instructors, and even students themselves, to be aware in real-time when inequitable behaviors are occurring on their teams, and to know how to address them. the consequences of inequitable teams are serious, leading to inequities in mastery experiences and ultimately contributing to students leaving engineering degree programs. to address this problem, this project introduces a digital pedagogical tool, called tandem. tandem holds promise for disrupting inequitable team behaviors. developed at the university of michigan, tandem is a multi-faceted tool for course teams that delivers tailored lessons to students about effective teamwork. the tool provides feedback to students and instructors about how teams are doing. the objective of this project is to study the effectiveness of tandem in assessing and supporting inclusive and equitable teamwork in engineering. this project seeks to improve the **\*\*diversity\*\*** of students that participate in engineering as well as improve novel educational tools. further, the project will address two components of the research agenda outlined in the national research council's discipline-based education research report. this includes conducting research that: 1) seeks to understand similarities and differences between student groups that differ by, for example, gender

and race/ethnicity; and 2) goes beyond assessing gains in conceptual understanding by focusing on outcomes associated with affective dimensions of learning. using mixed method study designs, this project will address the overall objective through the following research questions: 1) in what ways can tandem be used to observe inclusive and equitable teamwork in engineering? and 2) in what ways can tandem be used to support more inclusive and equitable teamwork in engineering? while tandem is currently being used across a range of courses at the university of michigan, the scope of the project will be limited to engineering 100, the cornerstone first-year engineering design course. engineering 100 is a useful context in part because small differences in teamwork experiences early in a student's college coursework can be magnified in subsequent team project experiences and because the first and second years in college are considered the most impactful in terms of retention and persistence of stem majors. key data sources include data from student surveys and responses to lessons collected throughout the term in tandem, student interviews, and observations of engineering student teams during class meetings. the expected outcomes from this work include 1) generalizable knowledge about an approach to measuring teamwork competency that emphasizes inclusion and equity and fosters instructor and student awareness of inequitable team behavior, 2) improvements to survey and lesson features within tandem that will support the ability of teams to behave inclusively, and 3) improved pedagogical practice in this engineering course context. the positive impacts of this project will be further propagated through the use of tandem in other team-based courses at the university of michigan as well as at other institutions. this project has transformative potential in the tailored support that tandem can provide to instructors and students in recognizing and addressing inequitable behavior in teams and promoting conditions in which all can be successful. the nsf iuse: ehr program supports research and development projects to improve the effectiveness of stem education for all students. through the engaged student learning track, the program supports the creation, exploration, and implementation of promising practices and tools. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts

review criteria.

Title: Collaborative Research: FET: Medium: Neuroplane: Scalable Deep Learning through Gate-tunable MoS<sub>2</sub> Crossbars

Awardee: Purdue University

Amount: \$299,742.00

Abstract: the increasing complexity of deep-learning systems has pushed conventional computing technologies to their limits. while the memristor is one of the prevailing technologies for deep-learning acceleration, it is only suited for classical learning layers where two operands, namely weights and inputs, are processed at a time. meanwhile, to improve the computational efficiency of deep learning for emerging applications, a variety of non-traditional layers, requiring concurrent higher-order processing of many operands, are becoming popular. for example, hypernetworks improve their predictive robustness by simultaneously processing weights and inputs against the application context. two-electrode memristor grids cannot natively support such operations of emerging layers. addressing the unmet need, this research will develop neuroplane -- a novel deep-learning accelerator of gated memtransistor crossbars. exploiting crossbars' gate controllability, multiple operands can be processed within the same crossbar unit in neuroplane. many advanced inference architectures that can generalize beyond a typical passive crossbar will thus be possible. overall, the ultra-low-power, higher-order processing of neuroplane will harness high robustness and efficiency of emerging deep-learning layers within area/power-constrained devices such as mobile, sensor, and embedded systems. the investigators will develop fabrication methods for nanometer node gate-tunable dual-gated crossbars of mos<sub>2</sub> memtransistors. a self-aligned fabrication method with defect passivation and process variability compensation will be created. exploiting the gate-tunability of mos<sub>2</sub> memtransistors, a new generation of crossbar platforms with many runtime control knobs will be developed, rendering the design a high elasticity

and agile computing space. for example, computing methods will be created for the gated crossbars to utilize crossbar elements for product-sum digitization, thereby preventing the critical overheads in current crossbar technologies. similarly, control-flow methods will be developed for gated crossbars to adapt their inference paths depending on the input characteristics by dynamically deactivating input/output neurons to conserve processing energy. a coherent collection of software and hardware-based correction techniques is proposed to minimize the impact of process variability. unlike the current schemes, by following the train-once-deploy-anywhere tenet, the proposed crossbar correction methods can scale to millions of deployments without considerable overhead. an annual workshop will be conducted at local high schools with substantial ethnic and gender **\*\*diversity\*\*** to mentor underrepresented students. undergraduate research projects will be sponsored using paid summer internships and university-level programs such as summer undergraduate fellowship. an inter-university senior-design mentoring program will be created for students among participating institutions. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: IRES Track 1: The long-term impacts of extreme climate events on the behavioral ecology, fitness and population viability in wild bottlenose dolphins, Australia

Awardee: Georgetown University

Amount: \$299,599.00

Abstract: this international research experience for students program will support at least three u.s. undergraduate and two u.s. graduate students each year (15 students in total) to collaborate with researchers in australia to investigate the long-term impacts of an extreme marine heat wave on a population of indo-pacific bottlenose dolphins (*tursiops aduncus*) that has been studied since 1984. students will conduct field work in shark bay, western australia (a unesco world heritage site with the

highest vulnerability rating according to the climate change vulnerability index), and then wet-lab work at the university of the sunshine coast (queensland, australia). students will use behavioral and genetic data to answer three questions regarding the dolphin population: 1) how does individual dolphin behavior change when their habitat is disrupted? 2) how does the individual's social environment and foraging strategies affect their ability to respond to environmental change? and 3) how does habitat fragmentation affect genetic and social connectivity throughout the population? students will gain computational, field and wet-lab skills from addressing these research topics, as well as policy skills and broad socio-cultural and biological perspectives on wildlife management from their collaborations with local stakeholders and government researchers. in this program students will be afforded a unique opportunity to study genotype-environment interactions in the wild, and bring back tools to apply to local conservation issues and wildlife management in the us.

in this program students will be afforded a unique opportunity to study genotype-environment interactions among wild dolphins, studied since 1984, and their responses to an extreme climatic event in a global bio\*\*diversity\*\* hotspot. in 2011, the most extreme marine heat wave on record devastated the shark bay ecosystem, leading to a 90% reduction in foundational seagrass coverage, the collapse of local fisheries, and significant changes to the abundance and distribution of marine megafauna, including bottlenose dolphins. shark bay dolphins exhibit a diverse behavioral repertoire including tool use, multiple foraging tactics, highly differentiated social bonds, and distinct social and ecological phenotypes. this behavioral heterogeneity allows us to investigate the adaptive value of such traits in the decade before and after exposure to an extreme climate event. student-led research will investigate the widespread impacts on the dolphin population, focusing on three areas of inquiry including fine-scale population structure, individual social and foraging behavior, and individual variation in reproductive success after the heatwave. our long-term 37+ year database of behavioral, ecological, genetic, and demographic data will allow students to analyze baseline population dynamics, parameterize simulations, and develop hypotheses. next, while in the field, undergraduate and graduate students will work together to collect data continuing

a decade-plus assessment of the behavioral and fitness consequences of environmental disturbance. participants will be trained by expert Australian collaborators in genetic data analysis and the study of genotype-environment interactions. students will analyze population changes in the context of their impact on inbreeding potential, resource competition, social networks, and ultimate fitness consequences. the proposed integration of animal behavior and landscape genetics will advance our understanding of ecological and evolutionary principles by leveraging a natural experiment in rapid environmental change. this program affords a diverse group of students from the DC-Metro area international research experience in meeting some of the biggest environmental challenges we currently face. by contrasting local systems with international systems facing different environmental conditions, managed by different governments, with distinct regional complexity, students will gain extensive insight into pressing conservation problems. this award reflects NSF's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: StEM: Stimulate, Engage and Motivate student research by enhancing the research capacity (CISE-MSI: RCBP-ED: IIS ? III)

Awardee: SUNY College at Old Westbury

Amount: \$299,498.00

Abstract: this award is funded in whole or in part under the American Rescue Plan Act of 2021 (Public Law 117-2). exposure to research is one of the best predictors of degree completion and success in postgraduate education among students pursuing degrees/careers in STEM fields. however, only a small percentage of undergraduate students are engaged in research. this lack of participation has been attributed to factors such as interest in more applied experience, lack of awareness about research opportunities and their benefits, lack of time, lack of interest, perceived barriers to interactions with the faculty, and personal and financial barriers. the problem further aggravates with

little participation from underrepresented minority groups. additionally, biases in several sectors of computer science are evident due to the historical underrepresentation of researchers. significant evidence shows that engaging undergraduate students in research builds confidence and efficacy, motivates them to pursue advanced graduate level stem courses, increases retention in majors having high attrition rates, and acclimates them to the demands of a research environment. in addition, underrepresented minority groups students? participation in research is beneficial to the field as it enhances **diversity** in the stem workforce. the goal of this project is to stimulate, engage, and motivate graduate and undergraduate stem students, including from underrepresented minority groups to conduct data research in different domains, while supporting expansion and enhancement of research capacity to provide more research opportunities to the diverse student population and the faculty. this goal will be achieved by following a three-pronged approach to 1) enhance and expand the technological infrastructure by acquiring new equipment to facilitate computational processing and big data analyses; 2) embed research within the curriculum for existing courses via cure and introduce new research-focused programs and courses; and 3) motivate and engage students in research activities and provide hands-on experience via research projects, training, seminars, and workshops through guidance and mentoring by academia and industry experts. the award will improve the academic and professional skills of stem students, in particular female and other underrepresented minority students, provide an opportunity to work with experienced research mentors and present/publish their work, create educational materials for long-term enhancement of academic curricula, and foster knowledge and promote the developmental skills to prepare students for data science and big data careers. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: IRES Track I: Engaging students in management oriented research to conserve rainforest

primates in Uganda

Awardee: CUNY Hunter College

Amount: \$299,439.00

Abstract: to successfully conserve rainforest primates, the current challenges affecting their survival in the wild need to be identified and addressed. this type of research requires interaction among scientists and wildlife managers to solve conservation problems. through this ires funded project, u.s. undergraduates and first year graduate students from hunter college of the city university of new york will conduct integrative management-oriented research that is aimed towards addressing primate conservation in uganda. during 8-week summer experiences over three years, eighteen students will conduct collaborative research with park wardens of the uganda wildlife authority in kibale national park, uganda, a tropical rainforest national park that hosts high densities of primates. students will tackle problems related to three pressing conservation themes: 1) global change and primate nutrition; 2) ecotourism of wild apes; 3) invasive plant species in primate habitats. by undertaking this research, students will be involved in an immersive experience in uganda where they will gain field experience and learn about ugandan culture at makerere university's biological field station. they will develop their scientific skills by writing a research proposal that addresses primate conservation, constructing testable hypotheses and conducting fieldwork. students will then analyze, report and discuss their results in several forums in uganda and the usa. they will learn how to communicate their results through the media in uganda by working alongside journalists and public relations professionals. hunter college is a minority serving institution and at least 50% of the students selected for this experience will be underrepresented minorities in the sciences. global change has pressing outcomes for tropical forests and their inhabitants even when they are protected in national parks. this is particularly true for monkeys and apes, because they grow more slowly, have longer lives and modest reproductive rates compared to most other mammals. to successfully conserve primates, empirical research needs to be combined with effective management. twelve undergraduates and six master's students will conduct research for eight

weeks in three summer cohorts in Kibale National Park, Uganda, a tropical rainforest in western Uganda that hosts a high **diversity** and density of primates. Students will investigate management-oriented research questions that will promote primate conservation under the guidance of Uganda Wildlife Authority professionals. They will engage in research foci under three themes: (1) students will investigate primate feeding ecology, nutritional chemistry of tree leaves, food availability and food density, and compare current patterns with long term datasets; (2) students will examine different parameters of ecotourism in relation to how it might affect chimpanzee ecology and behavior; (3) students will explore the ways that invasive and exotic shrubs affect plant community **diversity** and the primate food supply. At least half of all the student researchers will be underrepresented minority undergraduates and graduate students in STEM. Students will participate in conservation efforts and integrate their research into conservation plans. They will learn how to prepare media briefs and communicate their research findings to the Ugandan public. Students will also present their research within several forums in New York City, at Hunter College and in Uganda. This award reflects NSF's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Dynamics of Seasonal Forecast Uncertainty: Cross-Basin Ocean-Atmosphere Interactions

Awardee: University of Texas at Austin

Amount: \$299,130.00

Abstract: Every few years the Pacific Ocean warms dramatically in a narrow strip along the equator extending roughly from the South American coast to the dateline. This warming is called an El Niño event, and El Niños and their cold La Niña opposites are referred to collectively as El Niño/Southern Oscillation (ENSO) events. While ENSO events are broadly similar there are important differences, in

particular they differ in whether the sea surface temperature (sst) change is greatest in the eastern or central pacific. they also differ in their magnitude, and el nino events are often stronger than la nina events. the consequences of enso are felt worldwide, from changes in the indian monsoon to the severity of winters in canada, and these impacts vary according to the pattern and magnitude of the event. the dynamical mechanisms that cause **\*\*diversity\*\*** in behavior among enso events and their global impacts are thus an important practical problem as well as a topic of scientific interest.

this project examines the idea that much of the **\*\*diversity\*\*** of enso events occurs because of interactions between the developing enso event and a variety of less prominent climate variability modes occurring over the global oceans. for example the pacific meridional mode (pmm) is a variability pattern in which fluctuations of the aleutian low over the north pacific generate warm ssts (or cold, in the opposite phase) which propagate slowly toward the equatorial pacific through air-sea interactions. the overlap between the domains of the pmm and enso makes the pmm a likely suspect in diversifying enso events. likewise, the episodic warming of the indian ocean in the indian ocean dipole (iod) mode affects the trade winds in the western pacific, with potential consequences for enso given the central role of trade wind fluctuations in enso evolution. to examine the effect of secondary modes on enso **\*\*diversity\*\*** the principal investigators (pis) of this award take advantage of the ensemble method used to predict enso events. ensemble prediction means using a climate model to predict enso based on observed initial conditions (the state of the atmosphere and ocean at a given time) but performing several forecast simulations instead of one, and starting each forecast simulation with slightly different initial conditions. the resulting perturbed initial condition ensemble (pice) gives a best estimate of the evolution of enso and also estimates the uncertainty in the prediction. the idea of this project is that the individual forecast simulations in a pice contain different secondary modes, and the interactions between secondary modes and enso can be assessed by examining differences in enso evolution among the simulations. an advantage of this method is that a large database of pice simulations has been created by the earth system prediction (esp) working group of the community earth system model (cesm). the pice dataset provides a

much larger sample size than the observational record, thus statistically robust results can be obtained. the work is of societal importance given its direct connection to enso prediction. in addition to its examination of enso evolution in prediction simulations the research uses the pice simulations to understand how differences among enso events lead to differences in the impacts of enso in populous parts of the world. the project also supports two graduate students and provides internship opportunities for undergraduates. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Supporting Diversity to Increase Innovation: Building New Mexico's Computer Information Systems Technician Workforce through Equity and Inclusion

Awardee: Central New Mexico Community College

Amount: \$298,757.00

Abstract: the department of labor estimates that more than a million computing-related job openings will be available in the u.s. by 2024. it also estimates that more than two thirds of these jobs could go unfilled due to an insufficient pool of qualified applicants. addressing the underrepresentation of women and other minoritized groups in the computing workforce will help to close this predicted employment gap. evidence suggests that the resulting increased **\*\*diversity\*\*** of the workforce can also lead to increased productivity and better problem solving in the workplace. this project will investigate how to recruit, retain, and prepare women and minoritized students to pursue careers in computer information systems (cis). project goals include: 1) providing cis faculty at central new mexico community college with resources to support and retain traditionally underrepresented groups in cis technician majors; 2) introducing high school students to careers in cis, with a focus on girls and students from other minoritized groups; 3) preparing these students for success in postsecondary cis pathways; and 4) strengthening high school teachers' knowledge and understanding of cis careers. project efforts will focus on the entire pipeline, from high school teachers and students to college faculty and students in the cis program. the project intends to broaden participation in cis by recruiting high school students from minoritized groups, including women, into cis career pathways and supporting their success within the pathway. the project will leverage multiple approaches including providing high school students with cis skills workshops, paid internships, and courses that provide dual enrollment credit. it will also train college faculty to better support the educational journeys of all their students using customized curriculum. quantitative instruments will be developed to monitor the impact of activities on high school students.

descriptive statistics will be used to determine the baseline perceptions of cis and confidence in ability to learn cis skills. the student cohort will be surveyed over time to measure changes in attitude and behavior, as well as changes in their intention to pursue cis education after high school. this project is funded by the advanced technological education program that focuses on the education of technicians for the advanced-technology fields that drive the nation's economy. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Unconventional High Surge Impedance Loading Transmission Line

Awardee: Virginia Polytechnic Institute and State University

Amount: \$298,507.00

Abstract: to achieve net-zero emission in america by 2050, high voltage transmission capacity must expand ~60% by 2030 and triple by 2050 to connect further wind and solar facilities to demand. this expansion requires a capital investment in transmission capacity of \$360 billion by 2030 and \$2.4 trillion by 2050. we will fail to achieve a net-zero america by 2050 unless high-capacity overhead lines are developed. to tackle this problem, we will (i) develop a revolutionary and flexible design for transmission lines by shifting phase configurations and sub-conductors into unconventional arrangements that are geometrically optimized within the space, enabling a given high surge

impedance loading (hsil) design, and (ii) create and introduce a novel transmission expansion planning (tep) framework, where, given the possibility provided in (i), line parameters that do not play a role in traditional tep will now play key roles as variables in this new framework. this will lead to cost-effective planning scenarios and huge savings that cannot be achieved through conventional transmission lines. by combining (i) and (ii), this research plan introduces a new concept that we call smart tep-based unconventional hsil line designs that will revolutionize power delivery. the integrated education plan train the next generation of power engineers needed to maintain the competitive vitality of the u.s. workforce. we also collaborate with the center for the enhancement of engineering **\*\*diversity\*\*** at virginia tech on k-12 outreach activities designed to attract women and ethnic minorities to the field of electrical engineering. the proposed research pioneers power transmission loadability enhancement at the nexus of tep and unconventional hsil line design. the original and potentially transformative idea of engaging unconventional hsil line designs that address tep requirements is the cornerstone of this project. where conventional transmission lines fail due to insufficiencies in their self-reactive power compensation, unconventional hsil designs can (1) significantly increase power transmission loadability, (2) be creatively used for extra-high voltage, high voltage, and medium voltage levels for both transmission and distribution networks, and (3) decrease the need for lumped reactive power compensators. on the line design side, a very complex optimization problem will be solved to determine the optimal size, number, and location of sub-conductors in the space. another aspect is that tep itself has always been a complex optimization problem. in this research plan, we will complicate it further by making the line parameters that were fixed and predetermined in traditional tep now be variables. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Non-Profit and HBCU Collaboration to Establish a Plant Phenotyping Data Science

## Course-Based Undergraduate Research Experience

Awardee: Donald Danforth Plant Science Center

Amount: \$298,206.00

Abstract: this project aims to serve the national interest by increasing the **diversity** of students in the stem pipeline through the provision of opportunities for undergraduates at a historically black university to collaborate with plant and data science researchers via a course-based undergraduate research experience (cure). a vibrant and diverse stem pipeline is critical to the nation's economy, innovation capability, and economic prosperity. in the united states, this stem pipeline relies on diverse backgrounds, viewpoints, and experiences to improve innovation and outcomes, yet the participation of minority ethnic groups like african americans in the pipeline remains lower than their representation within the population as a whole. recommendations for building and sustaining a diverse and robust pipeline in stem call for increasing the number of mutually beneficial collaborations between faculty at historically black colleges and universities (hbcus) and scientists in traditionally white academic institutions. expansion of such collaborations would enable the numbers and types of authentic research experiences available to undergraduate students at hbcus to increase. current efforts to improve undergraduate stem education include the adoption of cures that can successfully engage large numbers of undergraduate students in authentic scientific research. cures in diverse disciplines including biology, biochemistry and chemistry are gaining prominence in undergraduate institutions as a successful strategy for growing the stem pipeline, but they are not prominent at hbcus. through this project, the donald danforth plant science center (ddpsc), a non-academic, non-profit plant science research facility, and harris-stowe state university (hssu), a hbcu, are collaborating to develop and offer a plant and data science cure. the overall goal is to increase the number of minoritized students in the stem pipeline. the american association for the advancement of science (aaas)'s 2011 report, vision and change, recommended that the biology education community prioritize providing opportunities for students to practice science through active engagement in research rather than just reading about it. experiences in research for

undergraduate students are known to greatly contribute to academic achievement, future career interests, and increased self-efficacy. despite such benefits, these research experiences have historically not been readily available to entire classrooms of students at minority-serving institutions. this project will enhance the scientific research skills of underrepresented racialized minority students through a cure which will train student in cutting-edge skills in image analysis and data science techniques, using image datasets from current scientific research studies. by major and by course (biology vs math) we will analyze various student learning outcomes, including self-efficacy, attitudes towards data science, position on a knowledge acquisition curve, and laboratory course assessment survey (lcas) scores. we will include in our model variables that might impact knowledge acquisition and self-efficacy using a generalized linear model (glm) that includes attitude, gender identity, race/ethnicity, educational background, major, and scores for collaboration, discovery/research, and iteration. to determine how collaborating with data scientists impacts students? perceptions of their role in research, we will use a mixed methods approach of analyzing the lcas results which will quantify student?s perceptions of their engagement in collaboration, discovery/research, and iteration. the nsf iuse: ehr program supports research and development projects to improve the effectiveness of stem education for all students. through the engaged student learning track, the program supports the creation, exploration, and implementation of promising practices and tools. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Amount: \$298,206.00

Abstract: this project aims to serve the national interest by increasing the **\*\*diversity\*\*** of students in the stem pipeline through the provision of opportunities for undergraduates at a historically black university to collaborate with plant and data science researchers via a course-based undergraduate research experience (cure). a vibrant and diverse stem pipeline is critical to the nation's economy, innovation capability, and economic prosperity. in the united states, this stem pipeline relies on diverse backgrounds, viewpoints, and experiences to improve innovation and outcomes, yet the participation of minority ethnic groups like african americans in the pipeline remains lower than their representation within the population as a whole. recommendations for building and sustaining a diverse and robust pipeline in stem call for increasing the number of mutually beneficial collaborations between faculty at historically black colleges and universities (hbcus) and scientists in traditionally white academic institutions. expansion of such collaborations would enable the numbers and types of authentic research experiences available to undergraduate students at hbcus to increase. current efforts to improve undergraduate stem education include the adoption of cures that can successfully engage large numbers of undergraduate students in authentic scientific research. cures in diverse disciplines including biology, biochemistry and chemistry are gaining prominence in undergraduate institutions as a successful strategy for growing the stem pipeline, but they are not prominent at hbcus. through this project, the donald danforth plant science center (ddpsc), a non-academic, non-profit plant science research facility, and harris-stowe state university (hssu), a hbcu, are collaborating to develop and offer a plant and data science cure. the overall goal is to increase the number of minoritized students in the stem pipeline. the american association for the advancement of science (aaas)'s 2011 report, vision and change, recommended that the biology education community prioritize providing opportunities for students to practice science through active engagement in research rather than just reading about it. experiences in research for undergraduate students are known to greatly contribute to academic achievement, future career interests, and increased self-efficacy. despite such benefits, these research experiences have historically not been readily available to entire classrooms of students at minority-serving institutions.

this project will enhance the scientific research skills of underrepresented racialized minority students through a cure which will train student in cutting-edge skills in image analysis and data science techniques, using image datasets from current scientific research studies. by major and by course (biology vs math) we will analyze various student learning outcomes, including self-efficacy, attitudes towards data science, position on a knowledge acquisition curve, and laboratory course assessment survey (lcas) scores. we will include in our model variables that might impact knowledge acquisition and self-efficacy using a generalized linear model (glm) that includes attitude, gender identity, race/ethnicity, educational background, major, and scores for collaboration, discovery/research, and iteration. to determine how collaborating with data scientists impacts students? perceptions of their role in research, we will use a mixed methods approach of analyzing the lcas results which will quantify student?s perceptions of their engagement in collaboration, discovery/research, and iteration. the nsf iuse: ehr program supports research and development projects to improve the effectiveness of stem education for all students. through the engaged student learning track, the program supports the creation, exploration, and implementation of promising practices and tools. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Tracking the movement and strength of the Northern Hemisphere westerlies over the last glacial cycle.

Awardee: Columbia University

Amount: \$297,771.00

Abstract: the westerly wind belts are a key part of the climate system. knowing the strength and position of the westerlies during different climate states and across abrupt shifts in climate would provide insight into the mechanisms of climate variability. studying the westerlies during past warm

intervals is particularly important because modern observations of weather patterns suggest that the westerly winds are moving poleward in response to global warming. the proposed study will document the strength and position of the northern hemisphere westerlies using sediment records of dust accumulation and upper ocean biological productivity. sediment cores from sites in the north pacific ocean will cover the last 150,000 years. they will include the most recent global warm interval roughly 130,000 to 115,000 years ago. the broader impacts of the proposed study include support for a postdoctoral fellow. the study also will provide opportunities for including high school students in hands-on research through the lamont high school intern program. that program builds on existing partnerships with new york city and rockland county high schools to recruit students from groups underrepresented in the earth sciences.

this proposed study will produce five ~150 kyr dust, productivity, and grain size records from the north pacific ocean to characterize the westerly winds during various mean climate states (peak interglacials of mis 5e and the holocene as well as peak glacials of mis 6 and the last glacial maximum), and how they respond to abrupt climate changes during terminations i and ii. these records will use samples from five marine sediment cores from a recent rv sonne research cruise to the north pacific (so264) that encompass ~15° latitude. these data will fill a gap in the current picture of a key region in the northern hemisphere and will serve as benchmarks for modeling studies. these datasets will be useful to both the paleoclimate and modern/future climate modeling fields, as they will provide constraints on the natural variability of the westerlies to changes in potential driving mechanisms such as ice volume and atmospheric temperature gradients, thus aiding essential modeling of future changes in the westerly winds. finally, the results of this work could serve as the impetus to perform similar studies in other regions of the world, such as the southern hemisphere, allowing questions related to hemispheric synchronicity of atmospheric circulation across various climate regimes to be addressed. the pi is the co-chair of the new lamont ldei task force and is deeply involved in implementing **\*\*diversity\*\*** programs on all levels, including active recruitment of underrepresented minorities in the geosciences. interpretations and conclusions drawn from this work will be brought to the public via

non-technical settings such as the annual lamont-doherty open house. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: CISE-MSI: RCBPP-RF: SHF: Towards Efficient, Reliable, and Secure Chaotic Communications in Wearable Devices

Awardee: California State University-Long Beach Foundation

Amount: \$297,448.00

Abstract: this award is funded in whole or in part under the american rescue plan act of 2021 (public law 117-2). wearable and portable sensors are finding their way into everyday life, not only as tracking devices but as diagnostic and treatment devices. wearable wireless devices require efficient secure communication solutions that meet the resource-limited requirements of such devices. to facilitate secure communications for low-power, implantable, portable, or wearable sensors, the encryption process must be integrated directly with the sensor's underlying hardware. chaotic circuits can be used to secure communication of resource-limited devices. chaotic systems are highly complex, unpredictable, and sensitive to their initial condition. however, they can be used to generate predictable responses if certain requirements are met. chaos can be utilized to hide data under noise, thus providing data confidentiality if used in wireless communication. on the other hand, applications of chaos in secure wireless communication have been limited to laboratory research. lack of solutions that maintain both ends of communication (transmitter and receiver) synchronized in real-world applications has limited the use of chaotic communication to research laboratories. to eliminate these issues and provide an efficient, reliable, and secure on-chip chaotic ciphering transmitter and receiver, this research aims to accomplish the following objectives. phase 1: delivering a chaotic low-power transmitter and receiver capable of real-time ciphering of sensory signals. phase 2: securing the underlying hardware of chaotic communication against piracy

and duplication by adopting a provably secure logic locking framework specifically designed for such systems. phase 3: developing efficient smart and machine learning algorithms to provide a dynamic matching of the transmitted and received signal. phase 4: ic prototyping and implementing the design in the physical form to ensure the functionality of the design. this research brings researchers from the department of electrical engineering and department of computer engineering and computer science in california state university long beach to provide a logic locked transmitter and receiver that can code and decode the signal using chaos in an efficient and reliable manner. the financial burden of healthcare has been preventing many, most among minorities and underrepresented groups from monitoring their medical condition and seeking treatment. wearable technology has seen an unprecedented increase in adoption in the last decade and can reduce the cost of healthcare. it can provide accessible care if security is implemented on devices at the design. if such devices are designed with efficient security, the public confidence, and subsequently their adoption, will increase. california state university, long beach is a minority serving institute ranked number four for **\*\*diversity\*\*** among united states colleges. by engaging diverse students in designing, implementing, and testing secure solutions for wearable health devices, this project aims to expand participation in computing and communication research. furthermore, secure wearable devices can enhance trust and adoption of such health-monitoring devices and increase access to affordable healthcare and improve health equity. the general progress of the projects, results, and datasets will be shared publicly through the website and git repository. the obtained results from this research will be disseminated in the form of publications, technical presentations, design reports, educational materials, dataset, and source code, and will be hosted publicly for the length of this project and beyond, on the investigator's website and git repository. the project git repository: [https://github.com/ahedaya/csulb\\_nsf\\_cise\\_msi](https://github.com/ahedaya/csulb_nsf_cise_msi) the project website: <https://avahedayatipour.com/research/hardwaresecurity> this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: EAGER: Geoheritage and Two-Eyed Seeing - Advances in Interdisciplinary Earth Science Research, Learning, and Inclusion through Shared Ways of Knowing

Awardee: Michigan Technological University

Amount: \$296,686.00

Abstract: geoheritage and two-eyed seeing (gts) is an exploratory place-based project that combines indigenous knowledge with geoscience education and research. a project team that crosses disciplines, generations and cultures will study dynamic and interconnected geologic and human stories about the landscape's past, present, and future. the project will employ equitable knowledge exchange and other ways of knowing to understand the foundations of earth processes. gts aligns with the pressing societal need to expand and support **\*\*diversity\*\*** in the geoscience community. the project engages innovative interdisciplinary perspectives and new expertise, which challenges conventional ways of thinking about the earth. the project aims to broaden considerations of the relationships between people, landscapes, and earth systems processes. the work is expected to contribute to the evolving field of geoheritage in the united states. results will demonstrate how braided knowledge system approaches nurture and complement deeper understanding of diverse perspectives and increase awareness of indigenous histories, language, and knowledge of geologic landscapes among the broader public. the diverse team will also cultivate social consciousness through shared dialogue on critical issues related to belonging, access, justice, equity, **\*\*diversity\*\***, and inclusion (bajedi) through amplifying currently underrepresented knowledge sets in the geoscience community. the project will result in the creation of a geoatlas that includes geologic, geographic and cultural data, which will be available to a range of stakeholders in the great lakes region. the project also engages tribal and non-tribal youth in digital storytelling and geoheritage research. in this project setting, the keweenaw region of michigan's upper peninsula on lake superior, gts explores relationships with the earth through the

lens of both anishinaabe-gikendaasowin (anishinaabe knowledge) and western science with two objectives: 1) the creation of a geoatlas ? a publicly accessible, exploratory geoheritage database that combines physical, cultural, and geographic datasets that will serve the scientific community, educators, local tourist entities, land use planners, and the broader public; and 2) cultivate youth leaders by fostering cultural competency in tandem with other essential skills for career paths in the geosciences. to achieve these goals an interdisciplinary team of great lakes indigenous knowledge holders, geoscience/geospatial researchers, and two cohorts of tribal and non-tribal youth will braid knowledge sets documenting the way that nibi (water), mishomis grandfathers (rocks), miskwaabik (copper), and geologic processes have guided and continue to mold culture and life. these qualitative data will be integrated as innovative geoheritage data layers in the geoatlas expressing these relationships in a holistic way offering potentially transformative impacts for the development of digital storytelling and long-term geoheritage research and increased cultural competency among the broader public. further contributions of this work include: a) cultivating a diverse geoscience community by introducing youth to geoscience career pathways through multi- disciplinary, -cultural, and ?directional learning about earth systems processes; b) creating foundations for transformative place-based, inclusive, and culturally-appropriate k-12 earth science and higher education geoheritage curriculum, both informed by gts project deliverables; and c) fostering a more diverse and equitable geoscience community through elevating currently underrepresented indigenous knowledge sets in the geosciences. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: CPS: Medium: RUI: Cooperative AI Inferencein Vehicular Edge Networks for Advanced Driver-Assistance Systems

Awardee: SUNY at Stony Brook

Amount: \$295,386.00

Abstract: artificial intelligence (ai) has shown superior performance in enhancing driving safety in advanced driver-assistance systems (adas). state-of-the-art deep neural networks (dnns) achieve high accuracy at the expense of increased model complexity, which raises the computation burden of onboard processing units of vehicles for adas inference tasks. the primary goal of this project is to develop innovative collaborative ai inference strategies with the emerging edge computing paradigm. the strategies can adaptively adjust cooperative inference techniques for best utilizing available computation and communication resources and ultimately enable high-accuracy and real-time inference. the project will inspire greater collaborations between experts in wireless communication, edge computing, computer vision, autonomous driving testbed development, and automotive manufacturing, and facilitate ai applications in a variety of iot systems. the educational testbed developed from this project can be integrated into courses to provide hands-on experiences. this project will benefit undergraduate, master, and ph.d. programs and increase under-represented groups' engagement by leveraging the existing \*\*diversity\*\*-related outreach efforts. a multi-disciplinary team with complementary expertise from rowan university, temple university, stony brook university, and kettering university is assembled to pursue a coordinated study of collaborative ai inference. the pis explore integrative research to enable deep learning technologies in resource-constrained adas for high-accuracy and real-time inference. theory-wise, the pis plan to take advantage of the observation that dnns can be decomposed into a set of fine-grained components to allow distributed ai inference on both the vehicle and edge server sides for inference acceleration. application-wise, the pis plan to design novel dnn models which are optimized for the cooperative ai inference paradigm. testbed-wise, a vehicle edge computing platform with v2x communication and edge computing capability will be developed at kettering university gm mobility research center. the cooperative ai inference system will be implemented, and the research findings will be validated on realistic vehicular edge computing environments thoroughly. the data, software, and educational testbeds developed from this project will be widely disseminated. domain experts in

autonomous driving testbed development, intelligent transportation systems, and automotive manufacturing will be engaged in project-related issues to ensure relevant challenges in this project are impactful for real-world applications. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Spectral Theory and Quantum Dynamics

Awardee: William Marsh Rice University

Amount: \$294,000.00

Abstract: this project aims to improve understanding of how the amount of disorder present in an environment can promote or suppress transport in a system. this issue is studied in the context of quantum mechanics at the atomic level. applications of new insights about quantum systems include the development of quantum computing devices and quantum algorithms. the project supports education and **\*\*diversity\*\*** through graduate student training, the supervision of undergraduate research, and the writing and publication of an introductory textbook on ordinary differential equations aimed at introducing undergraduate students to a rigorous treatment of this field. this project addresses the spectral analysis of schrödinger operators and unitary analogues of jacobi operators. these operators are relevant in many areas, primarily in quantum mechanics and approximation theory. the objective is to develop new approaches for the spectral analysis of these operators, and the methods employed range from functional analysis via harmonic analysis to dynamical systems and ergodic theory. the project also investigates the schrödinger time evolution in terms of transport and dispersion phenomena. the investigator seeks a complete spectral analysis of schrödinger operators with potentials generated by hyperbolic transformations, a proof of several conjectures in the context of orthogonal polynomials on the unit circle, an approach to proving zero-measure spectrum for multi-frequency schrödinger operators, and a study of quantum

dynamics from the perspective of transport exponents and dispersive estimates. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Effects of Mentoring Relationship Heterogeneity on Student Outcomes among NSF Research Experiences for Undergraduates (REU) Program Participants

Awardee: University of Utah

Amount: \$293,423.00

Abstract: understanding mentoring relationships is critical to increasing **\*\*diversity\*\*** in stem fields. researchers at the university of texas at el paso and the university of utah propose to study the effects of mentor relationship mismatch on student outcomes during nsf research experiences for undergraduates (reu) programs. this project aims to employ a novel approach to studying mentoring by examining multilevel mentoring and demographics of students and the mentor team. the project aims to collect data from participating students and mentors from across the country at the end of the summer research program and during the next year to gauge outcomes related to stem interest and persistence and intent to follow a stem career pathway. this project aligns with the ehr core research program's goal of addressing challenges in stem interest, learning, and participation.

the project aims to address three interrelated research questions, including how mentoring relationship heterogeneity impacts short-term and mid-term student outcomes, if these effects can be moderated by interactional dynamics between mentors and mentees, and how mentoring relationship heterogeneity impacts educational, research, and career goals immediately after the reu experience and after one year. mentoring relationship heterogeneity in context provides a conceptual framework focusing on how student mentees match with multiple mentors, including graduate students and post-doctoral researchers. the concept of programmatic heterogeneity will be used to measure the dissimilarity between students' demographic background and the

demographic composition of their reu program. post-reu surveys collected from the center for the improvement of mentored experiences in research (cimer) data will be used along with a matrix analysis of semi-structure individual interview responses. short-and mid-term student outcomes consist of immediate gains in working like a scientist, comfort with science skills, science identity, sense of clarity about career path, research productivity, persistence in stem major, and intent to pursue graduate school. the project seeks to advance knowledge about mentoring relationships and aims to produce mentor and mentee workshops to positively impact undergraduate research students from underrepresented groups. the project is funded by the ehr core research program that supports fundamental research focused on stem learning and learning environments, broadening participation in stem, and stem professional workforce development. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: BPC-DP: Building Ecosystems of Belonging for Neurodiverse Computer Science Students

Awardee: SUNY at Buffalo

Amount: \$293,110.00

Abstract: the university at buffalo's open education lab is designing and testing neuro\*\*diversity\*\* micro-credentials to create an ecosystem of belonging in undergraduate computer science programs. micro-credentials, similar to digital badges, are tools that can deliver bite-size curriculum and then both assess and verify learning for a given audience. in this case, students are the audience; this training is designed to increase instructor preparedness for teaching neurodiverse computer science students in undergraduate programs while presenting students with information about their instructors' training through digital badges. neuro\*\*diversity\*\* refers to differences in cognition and brain development common to conditions such as autism spectrum disorder and attention-deficit/hyperactivity disorder (adhd). these students are often attracted to stem career paths and possess traits that would make them valuable members of the united states' computing workforce, but drop out before graduation when they encounter misaligned teaching practices or instructors who discourage accommodations and supports for students with invisible disabilities. these micro-credentials are designed to give instructors the training they need to be able to transform their practice for neurodiverse undergraduate computer science students, as well as providing students with opportunities to identify trained instructors. in a process guided by the universal design for learning framework, which is used to create educational interventions that will meet the needs of as many students as possible, the project consists of two major components. the curriculum for the training is comprised of prior, piloted adhd training course for teachers and additional evidence-based strategies for improving educational success among diverse computer science students. the digital badges (micro-credentials) are co-designed with students and faculty to design a system of delivering curriculum to instructors and displaying instructor training to students. as instructors complete courses, badges display instructor preparation and willingness to learn about student needs directly to students. this allows students to identify instructors who will be safe to talk to about their needs and trained to support them, whether choosing mentors or making class selections. micro-credentials are evaluated at multiple stages of the co-design and implementation process to iterate on the design. the micro-credentials and curriculum will be published on the open

education lab's website at the completion of the project to allow other schools to access and update the tools. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: OCE-PRF: Variability in connectivity and receptivity of highly dynamic coastal ecosystems: implications for community structure and function in a recipient soft-sediment ecosystem

Awardee: University of California-Los Angeles

Amount: \$292,243.00

Abstract: this award is funded in whole or in part under the american rescue plan act of 2021 (public law 117-2). coastal ecosystems face pressures from both the land and the sea, including development and sea level rise. it is important to better understand how coastal ecosystems function so that predictions can be made about how they may change under future conditions and to better manage these environments now and in the future. this project will use long-term data, observational studies, and experiments to learn more about the relationship between kelp forests and sandy beaches. specifically, this project will explore how waves, tides, and sea level control the amount of kelp wrack that washes ashore, how the condition of kelp forests impacts the ecology of sandy beaches, and how beach wrack provides habitat and food for animals that live or find food on

beaches. this project will develop new research methods using drones and start new, long-term monitoring datasets that will contribute to the conservation of these important coastal ecosystems. additionally, this project will support the next generation of marine scientists and increase **\*\*diversity\*\*** in the field by providing research opportunities and mentoring to under-represented minorities at the undergraduate and high school levels. this project will also increase community awareness of coastal ecosystems and conservation issues through earth day participation, guest lecturing at public high schools, and public biology days at the university.

cross-ecosystem connectivity is a critical feature of many ecosystems and has important implications for food webs, bio**\*\*diversity\*\***, and ecosystem functioning. sandy beach ecosystems provide a unique study system for the role of ecosystem subsidies because of strong natural gradients in the type and amount of marine wrack inputs and the dependence of multiple trophic levels on wrack for food and habitat. the proposed research will use a combination of observations, experiments, and theory to explore how environmental attributes, including ecosystem connectivity, food web subsidies, and natural variation work across scales to affect multiple levels of biological organization and ecosystem functioning. this study will utilize nearshore rocky reefs and sandy beaches to understand the fate of subsidies under varying environmental conditions, determine how variability and stability in a donor ecosystem affects the structure and function of the recipient ecosystem, and to explore how variability in the type and supply rate of subsidies affects its colonization and remineralization. this project will also initiate and contribute to long-term monitoring datasets and utilize unoccupied aerial vehicle-based methodology and analyses to quantify ecosystem subsidy dynamics and fate across spatial and temporal scales. using a natural gradient in kelp forest persistence and a manipulative field experiment varying subsidy inputs, it will explore how subsidy variability impacts the bio**\*\*diversity\*\*** of multiple sandy beach trophic groups. field experiments will be utilized to better constrain the dynamics and fate of subsidies over time and across a range of oceanographic and beach conditions. this research will expand understanding of the coupling between kelp forests and beaches and the fate of detrital kelp export. results from field surveys and

experiments will also further elucidate the importance of ecosystem connectivity for critical ecosystem functions from promoting and maintaining bio\*\*diversity\*\* to secondary productivity and other aspects of this detrital food web. this study will have implications for management and conservation of coastal ecosystems in the face of reduced connectivity, increased variability, and loss of food resources and habitat associated with global climate change and other direct anthropogenic pressures. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Assessing Peer Mentorship as a Scalable Intervention to Promote the Academic Success and Retention of Diverse Undergraduate Biology Majors

Awardee: University of California-Santa Barbara

Amount: \$292,236.00

Abstract: this project aims to serve the national interest by improving undergraduate biology student academic success and retention in the major. at most universities in the united states, roughly 50% of undergraduate biology students leave the major within the first two years of their studies. to address this concern, most institutions put in place a number of first-year student support programs. there are, however, considerable challenges and significantly fewer supports for biology students in their second year of study when the student retention rate is at its lowest. this project seeks to improve the success of second year biology majors by implementing and characterizing near-peer mentorship programs at two research-intensive, minority serving institutions. upper division biology peer mentors who have themselves overcome common barriers to student success will provide academic insights and supports tailored to their second-year biology major mentees. importantly, this project is intended to shed light on the theoretical mechanisms by which peer mentorship promotes mentee academic success. advancing understanding of how peer mentorship works may enable wide adoption and successful implementation of this strategy at a national level across various post-secondary academic settings. in turn, this should increase the number, quality, and **\*\*diversity\*\*** of students graduating with stem degrees. to assess the impact of peer mentorship,

this project will employ a rigorous randomized control research design that will enable the assessment of how peer mentorship influences mentee (1) short-term and longer-term academic performance and retention and (2) sense of belonging, academic self-efficacy, and academic habit complexity. additionally, the project will include a focus on identifying and investigating effective near-peer mentorship practices to assess how these behaviors impact mentee outcomes. to assess whether peer mentorship is a scalable intervention at diverse universities, this project will implement peer mentorship programs at two large, public hispanic-serving institutions where both biology programs share similar academic challenges at the second year level. the mentorship structure will include mentee:mentor cohorts in 6:1 ratios, a seminar course where mentees participate in guided discussions on topics relevant to student success, and weekly mentor check-ins. to characterize these mentorship structures and achieve the previously mentioned goals, data will be collected from a variety of sources. institutional research groups at each project site will provide academic grades, major declaration, and demographic data for mentees, while project-generated survey instruments will capture mentee noncognitive impacts and mentor behaviors linked with these outcomes. combined, these data will advance understanding of how peer mentoring promotes student academic success in challenging stem majors. the nsf iuse: ehr program supports research and development projects to improve the effectiveness of stem education for all students. through the engaged student learning track, the program supports the creation, exploration, and implementation of promising practices and tools. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Explaining Differential Success in Biodiversity Knowledge Commons

Awardee: Arizona State University

Amount: \$292,095.00

Abstract: scientists increasingly rely on community-governed digital portals to store and access open data. while these digital portals have improved access to data and other scientific products, portals are expensive to implement, challenging to maintain, and often fail to have uptake among key stakeholders. like those working in other areas of the digital economy, scientists have increasingly adopted platforms to implement and tailor portals to particular communities and needs, a model that lowers infrastructure costs and enables benefits of scale across networked portals. yet portals built from the same platform nonetheless show a large variation in their outcomes. participation in any particular portal is often short-lived and the impacts of data portals on the scientific process are challenging to evaluate; portal usage typically fails to map onto traditional measures of research productivity such as publications and citation counts. this project is the first to systematically investigate scientific data portals built from a common platform in order to understand portal communities and outcomes. the research design, which compares bio\*\*diversity\*\* data portals, will inform studies of other platforms and digital knowledge commons, such as open source software and peer-production communities. specific findings and recommendations will be shared with bio\*\*diversity\*\* portal stakeholders regarding the effective design and use of these portals in order to improve uptake and access to these important species data and facilitate science and decision making around environmental change. this project uses fuzzy set qualitative comparative analysis (fsqca) to analyze open data portals as a kind of knowledge commons that impose minimal restrictions on access or reuse. the study sample comprises the 37 active and 4 inactive bio\*\*diversity\*\* data portals built from the symbiota platform, one of the largest and earliest scientific data platforms still under continual development, with hundreds of participating bio\*\*diversity\*\* collections and several dozen individually managed portals. in 2020, symbiota portals collectively provided access to over 60 million bio\*\*diversity\*\* data records and accounted for 90% of web traffic accessing specimens digitized through the nsf's advanced digitization of bio\*\*diversity\*\* collections (adbc) program, which has invested over \$50 million in this area to date. the project synthesizes across multiple types and sources of quantitative and qualitative data to identify why

some of these portals achieve sustained growth and others do not. to do so, the project collects and analyzes up to ten years of analytics and other information from the portals, including tracked usage data, community building activities, features of portal governance, and resource inputs, as well as observation data collected during portal site visits and interviews with a stratified sample of portal managers. the fsqca approach enables comparative inferences about those portal features most likely to foster productive and sustained outcomes, including collective benefit and building inclusive scientific communities. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Humanistic STEM: Blending Humanities and STEM to Increase Undergraduate Student

## Engagement, Knowledge, and Skills

Awardee: Embry-Riddle Aeronautical University

Amount: \$291,873.00

Abstract: this project aims to serve the national interest by improving undergraduate stem education.

to do so, it will develop, distribute, and research a transferable humanistic stem (h-stem) undergraduate curriculum model that blends humanities and stem. h-stem is defined as "a blending of the study of science, technology, engineering, and mathematics with interest in, and concern for, human affairs, welfare, values, or culture." h-stem highlights connections between humanities and stem, while reinforcing the relevance of each. the project will support different levels of h-stem curriculum development, from individual modules for implementation within a course to full h-stem courses, as well as an h-stem undergraduate minor. project goals also include the development of the humanistic stem center to facilitate integration of the humanities and stem disciplines at other universities. employers in stem fields have stressed the need for students to develop skills such as creative problem solving, critical thinking, ethical reasoning, and communication. these are skills are often best developed in humanities courses. the institutions participating in this project will work to implement h-stem at a variety of institutional types to create a better prepared stem workforce.

h-stem is a targeted response to two main concerns: (1) a false dichotomization of ways of knowing and skills as either humanities- or stem-focused, a situation exacerbated by institutional silos; and (2) the devaluing of skills associated with the humanities as less important, or even irrelevant, to stem students. the most significant product resulting from this project will be a model for blending humanities and stem content in ways that result in students achieving a deeper realization of the connections between these meta-disciplines. h-stem can also lead to more profound student understanding of the wide applicability of the skills and competencies they acquire in their courses. project leadership will develop an assessment framework that will use direct empirical data to measure project impact and inform future action. evidence from a pilot shows that h-stem students can apply interdisciplinary knowledge, concepts, skills, and methods of inquiry attained in academic

settings to produce creative responses to complex problems and situations. these skills allow the students to blend their technical competence with the creative and critical thinking skills that are increasingly essential for continued success in any stem field in the united states. the anticipated result of broad implementation of h-stem will be stem-focused graduates who are more closely aligned with the expectations of industry leaders, possess the requisite technical skills, and have increased capacity for empathy, refined communication skills, and rich exposure to cultural **\*\*diversity\*\***. these outcomes will have full utility in areas of student lives beyond their jobs, regardless of discipline, learner level or workforce sector. through a dissemination plan that targets a variety of academic audiences, and the formation of a consortium comprising multiple institutional types, this framework has the potential to significantly impact multiple student populations. the nsf iuse: ehr program supports research and development projects to improve the effectiveness of stem education for all students. through the engaged student learning track, the program supports the creation, exploration, and implementation of promising practices and tools. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: REU Site: Tiling Theory, Knot Theory, Optimization, Matrix Analysis, and Image Reconstruction

Awardee: University of Washington

Amount: \$291,792.00

Abstract: this award is funded in whole or in part under the american rescue plan act of 2021 (public law 117-2). this reu site program will host nine undergraduate students for eight weeks in summers 2022, 2023, and 2024 at the university of washington bothell (uwb) for research experiences. students will provide their research preferences and work closely with a faculty mentor in groups of three. the research projects to be pursued at this reu site are chosen to be of interest to the greater

mathematical research community while being accessible to students with minimal background preparation required. the research groups will be strongly encouraged to publish their results in journals and present them at professional meetings. this reu site will prepare its student participants for research careers and graduate training, contribute to increasing **\*\*diversity\*\*** in the mathematical sciences, and encourage and prepare its participants to pursue graduate school. the research experience will be complemented by several outings and social activities to build team cohesiveness and networking. this reu site will focus on research problems in the areas of knot theory, tiling theory, matrix analysis, optimization, and image reconstruction. in the tiling theory group, the participants will experiment with known infinite families of tiles and use basic combinatorial methods to analyze patterns. they will also perform computer-aided explorations of potential minimal aperiodic protosets to determine aperiodicity and potential structure of associated markov partitions. in the non-smooth optimization group, students will work to improve the numerical performance of the emerging non-smooth spectral gradient methods. this project will also help develop students' scientific computing skills using matlab. in the knot theory group, students will explore various open questions, for example, identifying types of knots that arise as components of hexagonal mosaic links created from saturated diagrams and understanding splittable links from specific sizes of saturated hexagonal or parallelogram diagrams. in the medical imaging and optimization group, students will study the algorithmic framework, generate simulated data, and modify existing code to train the deep-learning-based prior and incorporate it into the reconstruction algorithm. this project will offer students the opportunity to gain exposure to cutting-edge concepts in imaging science and machine learning and develop mathematical programming skills. the matrix analysis group will explore open questions on nonnegative matrices, the field of values, the geometry of polynomials, discrete geometry, and number theory. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Enhancing Undergraduate Education in Botany through Teaching, Research, Representation, and Experience

Awardee: Old Dominion University Research Foundation

Amount: \$291,099.00

Abstract: this project aims to serve the national interest by increasing plant awareness and professional preparedness among undergraduate students for future careers in botanical sciences. a strong knowledge foundation in plant biology is needed to confront numerous issues of national and global significance (e.g., food security, habitat conservation, climate change mitigation, the bio\*\*diversity\*\* crisis, and human mental health and well-being). despite the overwhelming applicability of plant biology, professional and educational training in botany has been in decline since the mid-20th century. this project intends to reinvigorate plant biology at old dominion university (odu), a minority serving institution. the project will enhance course offerings, increase student involvement and representation, and prepare students for individualized futures through tailored mentorship, professional development, and research experiences. through these actions, this project aims to make significant advances in student recruitment to plant biology courses, research experiences, and professional careers post-graduation. additionally, this project has potential to increase \*\*diversity\*\* in odu's plant biology courses. in this project, an integrated approach will be implemented for undergraduate plant biology training within a biology department. the approach will emphasize experiential learning opportunities across all academic levels. this project builds on traditional curriculum reform through the formation of an impact learning community focused on plant biology, provision of professional development opportunities, and mentoring of students. regular assessments of the program and student surveys will aid in determining the effectiveness of experiential learning activities for promoting positive student outcomes in plant biology. the ultimate goal of this project is to increase student opportunities, involvement, and representation in plant biology courses and research experiences at old dominion university, thus

bolstering knowledge, skills, and confidence in tomorrow's plant professionals. the nsf iuse: ehr program supports research and development projects to improve the effectiveness of stem education for all students. through the engaged student learning track, the program supports the creation, exploration, and implementation of promising practices and tools. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: CAREER: Towards room-temperature quantum simulators enabled by halide perovskites

Awardee: University of Nebraska-Lincoln

Amount: \$291,039.00

Abstract: this award is funded in whole or in part under the american rescue plan act of 2021 (public law 117-2). non-technical description quantum effects are any phenomena that typically happen at small scales and cannot be explained by classical mechanics. there are many important research problems involving quantum effects that classical computers cannot fully solve. for example, the rational design of complex materials can require understanding the collective behavior of many atomic components and their quantum interactions. a quantum simulator is a device that can actively consider the complex interactions (quantum effects) to model these real-world complex systems in a programmable fashion. however, traditionally, these quantum simulators have to work at ultralow temperatures, making them expensive to prepare and operate. this career project aims to transform the field of quantum simulators through a combined research and education program focused on novel optical materials and their integration approaches for realizing quantum simulators at room temperature. specifically, the pi will synthesize novel new optical materials, integrate them with photonic structures, demonstrate functional room-temperature quantum simulators, and use them to study the rich exotic materials properties that are previously challenging to fully understand. an integrated education program will also expand quantum science and technology accessibility in

nebraska by working with teachers via workshops and labs to provide them with a scientific frontier perspective. additionally, this program will engage undergraduate and high school students in workshops and internships, with a particular focus on first-generation college students and students from traditionally underrepresented groups. these efforts aim to increasing the **\*\*diversity\*\*** and competitiveness of the future scientific workforce. technical description: the goals of this project are to reveal quantum phenomena previously observed only at low-temperature at room temperature (rt) with excitonic halide perovskites materials in the optical cavities and build a competitive quantum optics education program at the university of nebraska-lincoln. strong coupling between excitons and photons in high-quality optical cavities produces a new hybrid half-matter, half-light quasiparticle called exciton-polariton that exhibits ultras-small effective mass inherited from the photon and significant nonlinearity inherited from the exciton. these qualities allow exciton-polaritons to undergo a transition to bose-einstein condensation at rt, potentially enabling a broad range of applications, such as optical analog quantum simulators and low threshold polariton lasers. the project will significantly expand our understanding of how excitons interact at rt and form stable polariton quantum liquid in these new perovskite material systems. it also provides a fantastic photonic platform for exploring the macroscopic quantum phenomenon at rt without requiring complicated and expensive ultracold atoms, cryostats, or molecular beam epitaxy growth vacuum chambers. lastly, the tunable mode splitting in perovskite microcavities behaves as an effective magnetic field on photon spin, enabling studies on synthetic non-abelian gauge fields and topological physics at rt. this research, which will utilize nanofabrication, materials synthesis, and optical spectroscopy methods to study halide perovskite materials, promises to transform the field of rt polaritonics and quantum simulators. it will also undergird an integrated education program focusing on quantum photonics. a graduate course, various outreach pathways, and a k-12 teacher workshop, all featuring research frontiers in quantum photonics, will be developed with the ultimate goal of building a diverse, globally competitive workforce pipeline on quantum science, a critical knowledge frontier for the nation. this award reflects nsf's statutory mission and has been deemed

worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: CNS Core: Medium: Systems Support for Federated Learning

Awardee: University of Wisconsin-Madison

Amount: \$290,320.00

Abstract: traditional approaches toward applying machine learning techniques to end-user data often require copying all data to the cloud. this is not only expensive but faces data privacy risks as well. by analyzing data on the device where it is generated, federated learning aims to mitigate both cost and privacy concerns of centralized machine learning without sacrificing its benefits. this collaborative project brings together investigators from two institutions to develop building blocks for practical federated learning by addressing challenges arising from the **\*\*diversity\*\*** of user devices and the heterogeneity of data distributions in those devices. the project takes a three-pronged approach: (1) enable performance improvements for machine learning developers (e.g., judicious participant selection instead of randomly selecting participants); (2) provide efficiency improvements for service providers (e.g., redundancy elimination for data transfers); (3) enable end-users to control their data privacy (e.g., akin to app permissions in android) without sacrificing device usability. two core principles underpin these solutions: multi-tenancy both in the cloud and on individual devices; and maintaining theoretical correctness, convergence characteristics, and privacy/security guarantees of federated learning algorithms. widespread adoption of practical federated learning can fundamentally change how we gather insights from end-user data and how users value data privacy, because users may not have to sacrifice privacy for convenience in many cases. this, in turn, can force large corporations to rethink their data collection and usage practices, and influence policy makers to consider stricter privacy regulations. all software from this project will be open source. through outreach and new educational materials, this project will pioneer the

training of privacy-aware systems builders. this collaborative project will produce software artifacts, experimental harnesses, benchmarks, and results of running those benchmarks and artifacts. these materials will be available for public use under permissive open-source licenses at multiple locations, including <https://github.com/symbioticlab>. they will be retained for at least three years after the completion of the project. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: OCE-PRF Ecological consequences of seawater chemistry modification by ecosystem engineers

Awardee: University of Washington

Amount: \$290,149.00

Abstract: this award is funded in whole or in part under the american rescue plan act of 2021 (public law 117-2). this project will determine how ecosystem engineers shape communities by altering local chemistry. ecosystem engineers modify the physical properties of a habitat often via the dense aggregation of individuals (e.g. mussel beds, kelp canopies, etc.)and can harbor extensive bio\*\*diversity\*\* compared to unmodified habitats. such habitats can control resident communities through a variety of mechanisms including altering local chemistry. through laboratory and field experiments, this project will compare how the altered chemical environments within diverse assemblages of habitat-forming species can shape long-and short-term community resilience to chemical stress. results of this study will directly inform aquaculture, conservation, and restoration by revealing mechanisms available to prepare communities for more stressful oceans in the future. this project will additionally broaden participation in science by groups typically underrepresented in ecology by partnering with existing stem recruitment programs and allocating funds to compensate participants. in collaboration with local shellfish aquaculture and community education programs,

this project will also serve as the basis for education and outreach materials that are used to increase peoples? connection to the environment while educating them on topics related to environmental stewardship and scientific research in an academia-industry-community collaboration.

small scale alterations of seawater chemistry within biogenic habitats can be dominated by biological processes like respiration, photosynthesis, calcification, dissolution, and their combinations (e.g. macroalgal canopies vs coralline algal canopies vs mussel beds). each of these processes has different consequences for the seawater carbonate system in that they can, for example, either decrease or increase carbon dioxide concentrations (photosynthesis and respiration, respectively) or either decrease or increase alkalinity (calcification and dissolution, respectively). these processes additionally occur against a backdrop of further perturbations to carbonate chemistry by larger scale processes like ocean acidification or riverine discharge. this project will examine the ability of different habitat-forming ecosystem engineers to ameliorate diverse chemical stresses within the habitat they create and the time scales over which that amelioration occurs. short-term amelioration potential will be assessed by determining whether habitat preference of mobile or settling taxa differs under acute chemical stress conditions. by measuring growth rates of residents within diverse types of biogenic habitat this project will reveal amelioration potential during a resident organism?s lifetime. lastly, the ability of these habitats to drive resident adaption to chemical stress will be determined by tracking how strains of a locally adapted clam originating from different types of habitats perform in the face of chemical stress events. overall, this project, aims to reveal the chemical contexts under which various types of chemical modification by foundation species can either facilitate or inhibit the members of associated invertebrate communities across several time scales this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: The Impact of Relevance, Belonging, and Growth Mindset on Persistence in Economics

Awardee: St. Catherine University

Amount: \$289,083.00

Abstract: this award is funded in whole or in part under the american rescue plan act of 2021 (public law 117-2). this project aims to strengthen capacity in economics at msis through research on the impact of institutional setting on underrepresented racial/ethnic minority students and women in economics. the project will investigate to what extent the past findings on relevance, belonging, and growth mindset generalize beyond a single institution and how the university context interacts with students' development of an identity as an economist. lower relevance, belonging and growth mindset are

linked to worse grades and lower persistence in economics majors. this project proposes an important addition to our understanding of relevance, belonging, growth mindset, and persistence in economics by increasing the institutional and demographic breadth of research. broader representation in economics will lead to more inclusive businesses and policy and accelerate economic growth. this project will increase understanding of the roles that relevance, belonging and growth mindset play as potential barriers or levers for change across diverse settings. the project will use longitudinal surveys of students and faculty at 18 universities stratified by educational type to examine if relevance, belonging and growth mindset develop differently in economics classes at men's and women's colleges than at non-men's and co-educational institutions. collecting data on relevance, belonging, and growth mindset and persistence from approximately 1,800 students at different points in their educational trajectory at different points in time (a year apart) will facilitate distinguishing selection into institutions from the impact of experiences in those institutions. understanding the role of men's and women's colleges in promoting relevance, belonging, and growth mindset and persistence in economics will indicate important directions for interventions to promote **diversity** in economics. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Power of Us: Increasing Female Enrollment and Retention in Career and Technical Education Programs

Awardee: Durham Technical Community College

Amount: \$288,951.00

Abstract: the low participation of women in technical fields has been a matter of concern for many years. workforce-**diversity** data, from several major technology companies, show a significant underrepresentation of women in technical jobs. industry points to the narrow pipeline of women

pursuing degrees in technical fields as the primary cause of this issue. this project aims to address this issue by implementing measures to increase female enrollment and retention in durham technical community college's most male-dominated career and technical education programs of study. the average percentage of females enrolled in the targeted areas is only 13.5%, meaning that females, who represent 53% of the overall student population, are vastly underrepresented in the pursuit of such degrees. the project will use both proven and novel strategies and activities, as well as equitable and inclusive practices that other institutions can use to increase female enrollment and retention in traditionally male-dominated programs of study. this project will leverage durham technical community college's new makerspace to hold events and provide a place where students can gather to work, study, and socialize. making the "power of us" brand visible in the makerspace will contribute to the college's efforts to create a makerspace that is rooted in equity and inclusion, where all voices are welcome. this project will offer engaging, female-led, female-focused learning opportunities; provide support services that are tailored to the needs of female students; and otherwise, create an environment where female students can thrive in the targeted programs. through its commitment to this project the college seeks to root the makerspace in the ideals of equity and inclusion, making it a welcoming space for all. this inclusive makerspace model will be one that other colleges and organizations, both inside and outside north carolina, can utilize to create makerspaces that are welcoming to all. this project is funded by the advanced technological education program that focuses on the education of technicians for the advanced-technology fields that drive the nation's economy. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Sustainable ABI: Arctos Sustainability

Awardee: University of Texas at Austin

Amount: \$287,248.00

Abstract: an award is made to three partner institutions ? the museum of vertebrate zoology (univ. california berkeley), museum of southwestern biology (univ. new mexico albuquerque), and the texas advanced computer center (univ. texas austin) ? to perform critical technical and infrastructure work that will establish a sustainable framework for arctos, a database and collection management system. the arctos community is a group of museum-based professionals representing natural and cultural history collections at over 40 institutions that share in the governance, design, maintenance, and development of arctos. a primary objective of the arctos community is to make high quality data on bio\*\*diversity\*\* and cultural collections openly accessible and richly networked for multidisciplinary research and public understanding. this is accomplished through the arctos online platform, which serves primary species and cultural data to national and international users. these data are used to advance knowledge in a \*\*diversity\*\* of disciplines and serve as an archival record for future generations. additionally, the arctos platform is used as an educational tool where students access raw data to design original inquiries. the arctos community is dedicated to rigorous management of collections and their data, as well as mentoring and training the next generation of curators, collection managers, and scientists. arctos views collections comprehensively and promotes linkages across biological, earth science, art, archival, and ethnographic collections to add value and relevance for education and research. for example, cultural and archival records often contribute temporal, ecological, and behavioral dimensions to bio\*\*diversity\*\* data from identifiable species components or observations. many museums curate more than one type of collection, and arctos provides a comprehensive management solution integrating diverse disciplines. for the last 20 years, arctos has practiced the concept of the ?extended specimen network?. the richly annotated data in arctos creates a web of knowledge with deep comprehensive relationships between cataloged records and all of their derived and associated data, and by using reliable published resources for globally shared information such as taxonomy, people names, and geography. to sustain this community-driven infrastructure and resource, the arctos database

platform will complete migration to open-source technologies removing the need for costly software. other benefits include stabilizing web services, query responses and delivery, spatial functionality, among other core features. the arctos model of community engagement and development is attractive for collections of any size, including small institutions such as field stations that may lack it infrastructure, because of its ease of cloud-based access, community mentorship, and enterprise-level platform at scaled pricing. project activities and results will be accessible on the arctos websites (arctos.database.museum and arctosdb.org). this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Cultivating Innovative Thinking Skills in STEM Education

Awardee: Pennsylvania State Univ University Park

Amount: \$286,185.00

Abstract: this project aims to serve the national interest by enhancing innovative thinking skills in stem education, which is important for sustaining the nation's global leadership in science and engineering. student innovation competitions and challenges (iccs) play an important role in motivating, educating, and providing training grounds for the next generation of innovators. given the growth of iccs in higher education entrepreneurship and innovation ecosystems, this project will help advance the theoretical basis for explaining how these experiential opportunities build students' competence and self-confidence in innovation and help them discover their limitations and capabilities. specifically, the proposed work will validate a theoretical research model based on transformative learning theory with the overarching goal of helping stem students become more open to new ideas, different identities, social attitudes, and values while also enabling them with decision-making tools to evaluate alternative viewpoints. by advancing the stem education community's understanding of the roles and processes of iccs in cultivating an innovation mindset,

the project outcomes will lead to better integration of iccs within existing stem curricula, thereby helping more students to develop an innovative mindset. finally, a systematic investigation of strategies to attract a diverse group of students to iccs will facilitate broadening participation in entrepreneurial and innovation ecosystems. the project postulates that participating in iccs is a transformative experience for students as they gain deeper self-awareness of their capabilities in innovation and become more open and critically minded. to answer research questions related to this main hypothesis, the project puts forward a research model that synthesizes the transformative learning theory and kern entrepreneurial engineering network's 3cs (curiosity, connections, creating value) framework. the project's research activities are organized in five interconnected research thrusts: (i) capturing students' experiences in iccs through interviews; (ii) developing the transformative learning scale for the innovation mindset (tlsim) to assess transformations in students' mindset toward innovation; (iii) validating tlsim in various iccs and other experiential learning settings including internships and capstone courses; (iv) investigating the relationships among attributes of iccs, student backgrounds, transformative learning processes, and student outcomes; and (v) studying the factors that motivate diverse groups of students to participate in iccs. the project outcomes will generate new knowledge about how different aspects of iccs can facilitate transformations in students' mindsets toward innovation, thereby laying the groundwork to improve iccs' potential for building student agency and self-efficacy. in addition, the project outcomes will help to increase **diversity** and inclusion in stem fields in two ways. first, the research model's underlying hypothesis, which posits that transformative experiences lead to mindset changes, can stimulate new research on the effectiveness of stem-related activities in attracting more diverse students. second, by emphasizing open-mindedness as a key outcome of iccs, the project outcomes will support enhancing **diversity**, equity, and inclusion in entrepreneurial ecosystems. project results will be disseminated to the stem education community through technical conferences, engineering education journals, and academic social networks. the nsf iuse: ehr program supports research and development projects to improve the effectiveness of stem education for all students.

through the engaged student learning track, the program supports the creation, exploration, and implementation of promising practices and tools. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: GP-IN: Pathways to tribal geosciences careers through cultural connections to iconic landscapes

Awardee: Idaho State University

Amount: \$284,964.00

Abstract: this award is funded in whole or in part under the american rescue plan act of 2021 (public law 117-2). this project focuses on recruiting and retaining native american students into the geosciences through three strategies that engage with participants at multiple points of contact from junior high to undergraduate levels. people of native american descent make about ~4% of bannock county's population (home to isu), however they only represent about ~1% of isu's student population and less than 1% of isu geoscience majors. initially, pis plan to work with shoshone bannock jr./sr. high school teachers and tribal elders to develop geoscience curriculum and field-based activities that tie tribal culture to iconic landscapes of idaho and wyoming. secondly, a project mentor will focus on early-undergraduate and transfer student geoscience internship opportunities to facilitate career pathways. geoscience faculty and the mentor will connect students to campus resources such as native american student services, counseling and testing and the career path internship program for educational and career pathway support. lastly, pis will work with the isu bengal bridge program which is a transition program between high school and college to develop best practices for recruiting through field visits. this program will focus on recruiting native americans into the geosciences at idaho state university (isu) in collaboration with six educational and non-profit partners. the overarching goal is to increase the number and **\*\*diversity\*\*** of

geoscientists attaining undergraduate degrees in eastern idaho. to achieve this, the pis offer a three-pronged effort that will blend informal and formal geoscience learning ecosystem strategies with multiple points of contact across a continuum of education levels. the three levels of engagement for the participants include 1) building a sense of identity by offering summer professional skill building through a youth employment program and related activities, 2) accessing trained mentors who will engage in both professional and geoscience development elements and 3) providing access to a bridge transition program that will ready students to enter undergraduate programs. the activities in this collaborative network of partnerships are based on established community of practice and self-efficacy models that can effectively support diverse recruitment and retention. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Testing the timing and direction of mantle exhumation at the Iberia-Newfoundland margins with low-temperature thermochronology

Awardee: University of Southern California

Amount: \$284,753.00

Abstract: the change from continents to seafloor is an important tectonic process that leads to the formation of oceanic basins. continental breakup results in extreme thinning of continental crust and exposure of mantle lithosphere to the seafloor before the start of seafloor spreading. the best-studied margin is the iberia-newfoundland margin in the north atlantic. previous work on the iberia-newfoundland margin provides the foundation for our understanding of the structure of these basins. however, multiple models have been proposed, each with slight differences. the timing, direction, and number of faults have direct implications on the evolution of these margins, as well as subsequent seawater alteration, which affects the habitability of the seafloor. this study will address questions on timing and structure of faulting that leads to separation of continents. this study will use

the minerals apatite and zircon to evaluate the timing and direction of faulting, as well as when the margin cooled enough to allow key chemical reactions to occur. these key reactions are believed to be critical to understanding the evolution of life on earth. the project will engage with a usc communications phd student to produce a podcast mini-series that explores the scientific research in this proposal and scientific communication practices for diverse audiences. in addition, a graduate student in the pis lab will initiate the first **\*\*diversity\*\***, equity, and inclusion (dei) poster session for graduate and undergraduate students from the department of earth sciences and department of marine and environmental biology at usc. the complex interactions between faulting, magmatism, and serpentinization at hyper-extended margins have fueled geophysical, geochemical, and numerical modeling investigations for decades. however, there is still debate over first order questions about timing and mechanics of the transition from continental breakup to mantle exhumation and seafloor spreading. these include the temporal relationship of faults that accommodate mantle exhumation, the number and directionality of faults in the exhumed mantle section, and the thermal history of the lithosphere during mantle exhumation and seafloor alteration. this project is the first comprehensive low temperature thermochronology study to constrain the cooling history of the rocks exposed within and adjacent to the exhumed mantle section of the iberia-newfoundland margins, the only hyper-extended margin that has been systemically sampled. the project will use zircon and apatite recovered from igneous intrusions, syn-rift sediments, and exhumed continental crust from nine drill cores that make up a horizontal transect across the exhumed mantle section. these data will be used to track lithospheric cooling below ~200c (zircon (u-th)/he) and ~80c (apatite (u-th)/he), within the thermal window of serpentinization and ophicalcite formation, respectively. the results will be used to test proposed exhumation models and address three overarching research questions: 1) what is the temporal relationship between the faulting that accommodates mantle exhumation and seafloor spreading? 2) was the mantle exhumed along one major detachment or multiple faults? 3) how does the timing of mantle exhumation faulting relate to other tectonic and petrologic processes, including the onset of seafloor spreading, serpentinization,

and magmatism? these data will be used to evaluate whether faulting, serpentinization, and/or magmatism occurred over progressive exhumation from east to west or occurred in several locations simultaneously, with key implications for the transition from continental breakup to seafloor spreading and the relationship between magmatism, lithospheric extension, and mid-ocean ridge development. the rates and extents of serpentinization and opicalcite formation will also have implications for understanding the development of conditions suitable for life on earth. the project will engage with a usc communications phd student to produce a podcast mini-series that explores the scientific research in this proposal and scientific communication practices for diverse audiences. in addition, a graduate student in the pis lab will initiate the first **\*\*diversity\*\***, equity, and inclusion (dei) poster session for graduate and undergraduate students from the department of earth sciences and department of marine and environmental biology at usc. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: The Role of Marketplaces in the Development of Complex Society

Awardee: Howard University

Amount: \$281,040.00

Abstract: this multidisciplinary pilot project identifies prehispanic marketplaces and establishes a set of marketplace indicators that can be applied elsewhere in the world. in the process, the project works with students to train a new generation of archaeologists currently underrepresented in the field. the objectives address a research gap that impedes archaeology's contributions to economic theory. pre-modern markets offer particular promise for adding **\*\*diversity\*\*** to economic ideas. isolated from global capitalist forces, these markets allow researchers to re-examine foundational concepts ? such as money, credit, debt, and investment ? in non-western contexts, expanding understanding of how culture influences economic behavior. for both theoretical and methodological reasons, however, archaeologists have only recently begun to establish the undisputed existence of pre-modern markets. previously prevailing western theories created a false dichotomy between past and present economies and suggested that market exchange ? the transfer of alienable goods and services between strangers ? could not exist outside of capitalism. while recent research has challenged these theories, archaeologists still lack sound methods for investigating the physical manifestations of markets, market systems and marketplaces, which are often ephemeral, barely leaving a material imprint. few archaeological projects worldwide have even tried to identify marketplaces, and their locations remain an important missing component in pre-modern market research. to help fill this gap, eight independent research programs are cooperatively investigating a possible prehispanic regional market system by identifying marketplace locations. economic investigations in the region have lagged due to several factors, including a historical

mischaracterization of the past society which had been conceived as less complex than those of other neighboring groups. researchers now however have begun to search for marketplaces as a sign of economic complexity. while marketplace investigations across archaeological sites have already had some success, varying metrics have hindered the research. additionally, the dense vegetation covering sites makes it difficult to employ conventional approaches such as examining item distributions, which rely on surface collections. to ensure comparable results, collaborators on this project are examining marketplace indicators by using a cross-cultural set of marketplace indicators that depend on a combination of approaches from archaeology, botany, soil science, and physics. researchers are analyzing both old and new data according to common protocols to produce joint results that address the central research hypothesis: an integrated system of large and small markets existed in the region, allowing access to similar goods for households within it. these results will further establish precedents for future research in terms of both methodology and cross-program cooperation. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: The geological and paleoecological contexts of early Miocene hominoid evolution

Awardee: University of Minnesota-Twin Cities

Amount: \$280,789.00

Abstract: this award is funded in whole or in part under the american rescue plan act of 2021 (public law 117-2). this project examines the roles of time and environment in the adaptive evolution of early apes by advancing knowledge about the chronology, paleoecology, and species **\*\*diversity\*\*** for a set of geographically restricted fossil localities. the research design includes a series of fossil excavations to uncover new evidence of early apes and their habitats, combined with laboratory

analyses designed to aid in synthesizing and interpreting these discoveries. the scientific importance of this project lies in documenting early ape adaptive **\*\*diversity\*\*** within specific, highly-resolved chronological and ecological contexts, with major downstream implications for interpreting the origin and diversification of later apes, including hominins. more broadly, this project expands participation in research through training opportunities targeted to underrepresented groups, enhances scientific infrastructure by digitizing invaluable but currently inaccessible field records, and increases public engagement with science through outreach activities aimed at museums and public schools. fossil and molecular evidence indicate that the major lineages of humans and apes diverged during the early miocene (ca. 23-16 ma). the **\*\*diversity\*\*** of ape species and adaptations during that time greatly exceeds modern variation in this group making it difficult to interpret the evolutionary sequence and ecological contexts in which the suite of features shared by living apes and humans appeared. this project is organized around the central question: are differences among early apes tied to differences in paleoenvironments, ages, or both? to clarify these relationships, researchers pursue three specific aims: (1) establishing a rigorous chronology of early ape fossil sites; (2) generating high-resolution paleoecological reconstructions for undersampled ape localities; and (3) documenting the **\*\*diversity\*\*** of ape species during the early miocene. fossil excavations are conducted at a series of outcrops to better document ape **\*\*diversity\*\***, geological contexts, and habitat parameters. the project employs radiometric and magnetostratigraphy at correlated stratigraphic sections (aim 1); sedimentological, isotopic, and paleontological analyses (aim 2); and comparative, morphometric, and phylogenetic analyses of new fossil ape specimens (aim 3). integration of these study results can enable the researchers to contextualize the timing and ecological parameters associated with the emergence of key characteristics in the ape and human lineage, and to subsequently interpret how these early miocene primate communities contributed to the distribution of primates across broad regions. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: SHF: Small: Programmable Hierarchical Caches: Design, Programming, and Prototyping

Awardee: Rochester Institute of Tech

Amount: \$280,097.00

Abstract: as computing technology becomes ever more powerful, memory is larger but more complex, with different materials, configurations, and interconnects having different trade-offs among capacity, speed, and cost. because of this complexity, fully automatic solutions are increasingly sub-optimal and brittle. this project develops new designs of the memory hierarchy that are programmable and therefore can achieve better performance and provide stronger guarantees than conventional solutions used on current computer systems ranging from smartphones to supercomputers. the new programmability enables optimization in software and hardware in concert. since computer cost and speed depend on memory hierarchy, programmable designs can overcome the current limit in scalability and power efficiency. beyond its technical content, the

project advances teaching in the science of computer memory and strives to increase the **\*\*diversity\*\*** among participants in this area of research and development. specifically, the project develops a two-level programmable cache system called the lease cache and designs its programming techniques. it has three parts: automatic programming and optimization of the lease cache; hardware design and prototyping of a risc-v processor with the two-level lease cache on an fpga board; and lease-cache theory especially statistical properties and guarantees of the cache performance. through theories and prototyping, the new designs can retain software portability, ensure matching performance to current automatic solutions by default, and provide precisely defined cache performance properties. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Mass transport in Jupiter's magnetosphere -- driven by internal or external processes?

Awardee: Planetary Science Institute

Amount: \$279,536.00

Abstract: the sun emits a stream of particles called the solar wind. the solar system presents a wide variety of obstacles to the solar wind in the form of planetary magnetospheres. magnetospheres arise from the internal magnetic field of a planet and serve to deflect the solar wind from the surface of the planet. mass from the solar wind hits the magnetosphere and is diffused toward the poles and then carried out behind the planet in a structure called the magnetotail. io is a moon of jupiter that also provides particles to its magnetosphere from within, and so it can be used to trace the flow of particles from within the magnetosphere. this project will use observations of sulfur and sodium ions to trace out the diffusion of particles from within jupiter's magnetosphere to better understand the process of diffusion in magnetospheres. the project will use a dedicated telescope for their

observations. the project will also create a children's book, "the misfit telescope" with a companion website and social media stream that use the benefits of "diversity" in scientific instrumentation as a parable to illustrate the benefits of racial and cultural inclusivity. the proposed project will study the io plasma torus (ipt) around jupiter in order to gain insight into the jovian magnetic field. the project will use the io input/output observatory to make time domain observations of s ii and na lines in the ipt to determine the nature of diffusion of material. ioio is a small-aperture robotic coronagraph that operates nightly, contemporaneously recording narrow-band images of the ipt ins s ii. combined with a model of the ipt, the observations will show whether diffusion is driven by mass loading from io or by activity in the middle jovian magnetic field. the project's children's book will show the value of both being in the minority and havingg a different point of view and of being in the majority and accepting and respecting the minority point of view. the book will be produced by the planetary science institute's award winning public outreach team. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: State-Imposed Local Fiscal Rules and the Fiscal Health of City Governments in the US

Awardee: Georgia State University Research Foundation, Inc.

Amount: \$278,000.00

Abstract: this award is funded in whole or in part under the american rescue plan act of 2021 (public law 117-2). city governments across the united states provide public services that people rely on in their everyday lives. the ability of a city governments to provide a consistent level of services to their residents depend on the budget choices of the officials in state governments. in order to mitigate detrimental budget decisions such as patronage hiring, risky investments, incurring massive debt, and under-funding of pension and other post-employment benefits, state governments impose fiscal rules on their city governments. these fiscal rules are aimed to improve local fiscal discipline by

preventing the unsustainable growth of local spending, revenues, and debt, as well as ensuring that local budgets are balanced. state-imposed local fiscal rules include balanced budget requirements (bbr), debt limits (dl), and tax and expenditure limits (tel). this project will identify different provisions of these fiscal rules and examine if such rules actually shape the fiscal health of city governments. fiscal health refers to the ability of governments to meet their service responsibilities and other financial obligations. to achieve this goal, the project will collect data on state-imposed fiscal rules using a combination of legal research and surveys of state and city government officials. the literature on political economy suggests that one mechanism to improve government fiscal discipline is constitutional constraints. the prohibitive costs of gathering information about budget policies to monitor official's budget choices, and agency problems in setting budget agendas lead to the notion that it may be more effective to bind the actions of government officials through fiscal rules. bbrs, dls, and tels function as ex-ante constitutional constraints that limit government's budgetary choices. bbrs require governments to match their expenditures with revenues. tels control the extent to which governments can increase revenues, spending, or both. dls control the type and amount of debt that a government is authorized to incur. even though there are these fiscal rules, there is inadequate knowledge on whether these rules work as intended. while there are rich data on state-level fiscal rules, data on state-imposed local dls, bbrs, and tels are outdated or limited. the majority of research focuses on state governments as the unit of analysis, and the evidence on the effectiveness of fiscal rules is mixed. this research will take advantage of the **\*\*diversity\*\*** of fiscal institutional arrangements across the fifty states to examine the design of local fiscal rules. the project will use multi-year detailed data from comprehensive annual financial reports collected from cities to measure the different dimensions of fiscal health. the econometric analyses will involve different approaches to address a critical issue in the study of institutions, which is the potential endogeneity of fiscal rules. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: EAGER: Predicting the impact of microplastics on the microbiota and viral transmission by mosquitoes

Awardee: Texas Tech University

Amount: \$277,146.00

Abstract: plastic pollution has become one of the most pressing environmental issues. while larger plastic pollution cause concerns when ingested by animals, little is known about the effects of much smaller microplastics, which can be formed by the degradation of larger pieces of plastic. microplastics of a few microns in size are common, are difficult to remove from the environment, and are easily ingested by animals particularly invertebrates, yet their biological effects are unclear. this project will investigate the effects of microplastics on the microbiota of mosquitoes and examine if any alterations of the microbiota will affect the ability of the mosquito to transmit disease causing viruses. this project will also have broader impacts by developing discovery kits and classroom learning exercises targeting underrepresented students in local high schools in lubbock, tx to help educate the next generation of microbiologists and entomologists, and inform society about the risks of microplastic pollution. additional broad impacts and societal benefits will include scientific training of undergraduate students and graduate students to be the next scientific leaders. this research project will use interdisciplinary approaches and the combined expertise of the pi and co-pi in their respective areas of microbiology and entomology, and effects of nanomaterials, to determine the impact of microplastics on the microbiomes, immune response, fitness, and pathogen transmission in mosquitoes. in this project, aedes mosquitoes will be used as a model to investigate interactions between microbial communities, microplastic pollution, insect immunology, and arbovirus infection. this project will use novel metagenomic sequencing approaches and advanced microscopy. with the proposed creative, high-risk approaches to test how microplastics may change microbiome **\*\*diversity\*\*** at the microscale, this project may result in fundamental changes of our understanding

of microplastic pollution impacts on insect microbiomes and the ecology of pathogen transmission.

Title: Collaborative Research: Integrative ecological perspectives on extinction processes - a multi-proxy case study of Hispaniolan subfossil and extant rodents

Awardee: Johns Hopkins University

Amount: \$276,219.00

Abstract: this project brings together researchers and educators specializing in genetics, anatomy, and ecology to explore the factors that led to the recent extinction of endemic rodents on hispaniola. hispaniolan rodents provide an exceptional case study for examining the triggers and timeline of island extinction events. bio\*\*diversity\*\* loss is a global concern, and over 70% of mammalian extinctions in the last 500 years have occurred on islands. the caribbean has suffered the greatest species loss of any region in the world. fossil data generated from this project have the potential to contribute to conservation policy by clarifying which factors most contributed to extinction events, and will be helpful for understanding the disappearance of species on other islands. this project will contribute to education by providing mentorship to young scientists at multiple levels, including caribbean and caribbean-american undergraduates and by developing teaching modules for k-12 students. finally, a database of extinct hispaniolan mammals will provide better public access to scientific information both in haiti and the usa. this project will use morphometrics, stable isotope ecology, and ancient dna to (1) identify the ecological relationships among hispaniola's extinct endemic rodents, (2) determine the timing of species loss, (3) resolve phylogenetic relationships among extinct taxa, and (4) clarify extinction triggers. the research team will rely on previously collected fossil material from three paleontologically-rich caves on the tiburon peninsula in southwestern haiti. the data generated will allow a more nuanced understanding of the roles that

human behavior, climate, and individual species characteristics (e.g., body size, habitat, genetic **diversity**) have played in extinctions on hispaniola. the data generated can be leveraged by conservation biologists to inform conservation policy aimed at preserving the remaining biological **diversity** on hispaniola and in island systems more generally. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: SBIR Phase I: Key 360 Species Survival Database (K3SS)

Awardee: GODWIT KEY COMPANY

Amount: \$276,000.00

Abstract: the broader impact of this sbir phase 1 project is to create a more collaborative and efficient way for scientists to combat species loss. the project proposes to create the a centralized database for a complete view of all of the issues affecting species survival which can be tracked in real-time. this project will allow scientists to expedite their research while offering the public more transparency about environmental data. the company aims to provide a high level of transparency about what factors are directly and indirectly affecting species survival and provide actionable steps that businesses, organizations, governments, and individuals can take to make a difference that they can see in real-time, and model well into the future. they seek to democratize conservation and bring new skills, people, and funding streams to the science and practice of conservation. this sbir phase 1 project consists of the development of a comprehensive database, which exists in the cloud, that encapsulates all of the factors that affect bio**diversity**. the project will result in a robust data system that can host and pull environmental data from all over the world, track the populations of the world's species, and measure conservation support and influence from the general public. the project will also allow users to query data in the cloud and use artificial intelligence (ai) capabilities to further their research. the project will track both scientific data and data about support

efforts from conservation organizations and the general public. the tracking of these factors will inform decision-making bodies on what methods are most effective in preserving bio\*\*diversity\*\*. the core technical risk to be addressed through phase i research and development is standardizing diverse qualitative and quantitative data so that they can be used together. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: NSFGEO-NERC:Collaborative Research: Chemistry and Biology under Low Flow Hydrologic Conditions Beneath the Greenland Ice Sheet Revealed through Naturally Emerging Subglacial Water

Awardee: University of Minnesota-Twin Cities

Amount: \$274,887.00

Abstract: this project is jointly funded by the national science foundation's directorate of geosciences (nsf/geo) and the national environment research council (ukri/nerc) of the united kingdom (uk) via the nsf/geo-nerc lead agency agreement. this agreement allows a single joint us/uk proposal to be submitted and peer-reviewed by the agency whose investigator has the largest proportion of the budget. upon successful joint determination of an award, each agency funds the proportion of the budget and the investigators associated with its own component of the work.

weathering is an important process that releases nutrients that are essential for life from rocks and minerals in the earth's surface. this project seeks to understand the effect of large glaciers on weathering processes beneath the greenland ice sheet and the consequences for life. during summer, nutrients and other products are flushed out of the greenland ice sheet with water from melting ice. while these products have been sampled in spring and summer, it is not known how weathering processes are different during winter. in this project, researchers will sample the seasonal ice that forms in front of two of greenland's glacial outlets, isunnguata sermia and leverett

glacier, during the freezing months to assess the chemistry and microbiology processes that reflect wintertime conditions beneath the ice sheet ? periods when input of fresh meltwater is minimal. these samples will increase knowledge of winter conditions under the greenland ice sheet and help better understand the interior portions of the ice sheet which are largely inaccessible. such information will help in assessing past conditions, when colder atmospheric conditions resulted in minimal meltwater input through the ice sheet and to the glacial bed. these analyses will inform understanding of the role of glaciers on earth's nutrient cycles presently, under past ice age conditions, and in a future deglaciating world. the greenland ice sheet is a major exporter of biologically important elements to the world's oceans. however, most of our knowledge of chemical and biological fluxes from the ice sheet comes from the summer outflux of outlet glaciers whose channelized waters contact only a limited portion of the glacier bed. the majority of the glacier-bed interface contains slow-flowing, distributed waters not representative of this flux. the project will test the hypothesis that overwinter chemical and biological processes under outlets of the greenland ice sheet differ substantially from summer outflow and represent a window into widespread, but typically inaccessible, distributed flow. the principal sample collection method will be early spring coring of naled ice that forms at glacial termini from wintertime subglacial flow. chemical, mineralogical, and biological constituents of this flow will be compared to material emerging from the initial, peak, and terminal phases of the melt season. elsewhere in the arctic, the chemistry of frozen overwinter subglacial material shows significant limitation in oxygen or sediment supply compared with even the first spring melt, supporting the idea that naled ice reveals a unique overwinter system. the naled ice and outflow of isunnguata sermia and leverett glacier will be sampled over two years. these west greenland outlets differ by more than an order of magnitude in the size of the catchments they drain, thereby testing the effect of scale on biogeochemistry. naled ice structure will be characterized by ground penetrating radar and ice borehole temperature profiles. the aqueous geochemistry, stable isotopes of carbonate and sulphate, and mineralogy of the suspended sediment of ice and water will be assessed. these analyses will document changes in the mineral flux and supply of atmospheric

gases at the glacial bed between winter low flow conditions and peak summer melt. microbial abundance, **\*\*diversity\*\***, metagenomics, and stable isotopes of biomass will also be measured to understand the concomitant relationship between geochemical conditions and biological communities. researchers will incorporate findings into a number of outreach efforts including developing a new curriculum module for the center for earth and environmental sciences, providing research opportunities for underrepresented students as part of the bridge to research program and preparing hands-on activities for the market science program. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: OCE-PRF A transferable modeling approach to predict species distributions under changing conditions across multiple life stages

Awardee: Florida State University

Amount: \$273,561.00

Abstract: this award is funded in whole or in part under the american rescue plan act of 2021 (public law 117-2). understanding the distributions of species is fundamental to ecology, especially within the marine environment where biotic and abiotic variables are often dynamic over space and time. ecological models have been used to make inferences on species-environment relationships in addition to predicting past and future patterns of species distributions. however, these models are typically developed for a single location, time period, spatial scale, or species life stage, resulting in poor predictive accuracy beyond the study domain. this project will provide a new transferable modeling approach that is applicable to a wide range of species, which will be used to test predictions of current and future distributions of green turtles (*chelonina mydas*) in the gulf of mexico, brazil, and qatar. since there is a lack of information on how marine turtles in general will respond to climate change impacts, these results will provide a crucial evaluation of projected range shifts that

could be used by both conservationists and decision makers. this project will foster the integration of research and education through mentoring undergraduate students that identify as underrepresented minorities, teaching marine ecology and conservation at florida state university, hosting workshops on the analysis of animal movement data, as well as hosting public outreach events. these efforts to disseminate knowledge and results beyond traditional means within the scientific community will be used to engage future scientists and the general public on pressing ecological topics. the overall aim of this project is to develop a transferable modeling approach that can provide accurate and precise estimates of species distributions under changing conditions. this study addresses some of the challenges of model transferability through three hypotheses: 1) a model informed by biological processes and physiological constraints will exhibit greater transferability than those that do not; 2) the analysis of environmental variables at the scale of species perception will result in greater model transferability; 3) a model that accounts for differences among life stages will result in greater model transferability. these hypotheses will be tested using a large dataset of green turtle occurrences at three distant locations (gulf of mexico, brazil, qatar) with a flexible bayesian species distribution model. the use of independent datasets (from brazil and qatar) to validate the species distribution model (developed on data from the gulf of mexico) provides a unique opportunity to critically evaluate the spatial transferability of the model. the findings from this proposed work will provide a roadmap for the further development of transferable ecological models to predict bio\*\*diversity\*\*, disease outbreaks, and risks of biological invasions across global regions and possibly under future climate change impacts. elucidating the importance of biological mechanisms, scale, and life stage differences to ecological modeling is transformative because these factors have been largely untested with regard to model transferability. since predictions remain a major frontier in ecology, products of this work will be of broad interest to a diverse group of scientists, such as marine ecologists, biological oceanographers, fisheries scientists, and conservationists. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's

intellectual merit and broader impacts review criteria.

Title: OCE-PRF A transferable modeling approach to predict species distributions under changing conditions across multiple life stages

Awardee: Florida State University

Amount: \$273,561.00

Abstract: this award is funded in whole or in part under the american rescue plan act of 2021 (public law 117-2). understanding the distributions of species is fundamental to ecology, especially within the marine environment where biotic and abiotic variables are often dynamic over space and time. ecological models have been used to make inferences on species-environment relationships in addition to predicting past and future patterns of species distributions. however, these models are typically developed for a single location, time period, spatial scale, or species life stage, resulting in poor predictive accuracy beyond the study domain. this project will provide a new transferable modeling approach that is applicable to a wide range of species, which will be used to test predictions of current and future distributions of green turtles (*chelonina mydas*) in the gulf of mexico, brazil, and qatar. since there is a lack of information on how marine turtles in general will respond to climate change impacts, these results will provide a crucial evaluation of projected range shifts that could be used by both conservationists and decision makers. this project will foster the integration of research and education through mentoring undergraduate students that identify as underrepresented minorities, teaching marine ecology and conservation at florida state university, hosting workshops on the analysis of animal movement data, as well as hosting public outreach events. these efforts to disseminate knowledge and results beyond traditional means within the scientific community will be used to engage future scientists and the general public on pressing ecological topics. the overall aim of this project is to develop a transferable modeling approach that can provide accurate and precise estimates of species distributions under changing conditions.

this study addresses some of the challenges of model transferability through three hypotheses: 1) a model informed by biological processes and physiological constraints will exhibit greater transferability than those that do not; 2) the analysis of environmental variables at the scale of species perception will result in greater model transferability; 3) a model that accounts for differences among life stages will result in greater model transferability. these hypotheses will be tested using a large dataset of green turtle occurrences at three distant locations (gulf of mexico, brazil, qatar) with a flexible bayesian species distribution model. the use of independent datasets (from brazil and qatar) to validate the species distribution model (developed on data from the gulf of mexico) provides a unique opportunity to critically evaluate the spatial transferability of the model. the findings from this proposed work will provide a roadmap for the further development of transferable ecological models to predict bio\*\*diversity\*\*, disease outbreaks, and risks of biological invasions across global regions and possibly under future climate change impacts. elucidating the importance of biological mechanisms, scale, and life stage differences to ecological modeling is transformative because these factors have been largely untested with regard to model transferability. since predictions remain a major frontier in ecology, products of this work will be of broad interest to a diverse group of scientists, such as marine ecologists, biological oceanographers, fisheries scientists, and conservationists. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: EAGER: Using allies to expand your network: Implementing a psychological methodology to attract and retain underrepresented (UR) students in geoscience

Awardee: Texas Tech University

Amount: \$273,404.00

Abstract: geoscience maintains a base-rate problem with respect to \*\*diversity\*\*: ethnic minorities

and people with disabilities are highly underrepresented. this has been traced to a variety of barriers for underrepresented (ur) ethnic scholars including: a lack of geoscience majors at hbcus and primarily hispanic-serving institutions, a lack of experience with, and time spent in, nature (e.g., < 3% of visitors to u.s. national parks are black and hispanic), and negative attitudes about career prospects. for people with disabilities, the main challenge is accessibility and the provision of appropriate accommodations. ur individuals may self-select out of geoscience programs due to these perceptions and barriers. this project will test the idea that allies, or members of dominant social identities, are best situated to positively influence these statistics. academic allies, whether faculty or graduate student teaching assistants, have tremendous impact on their students? academic engagement and can serve as linchpins for improving the future trajectories of ur students. pis will train individuals in effective allyship behaviors, and incentivize them to recruit ur students into their academic field trips. the pis plan to target allies who engage in field research and education, as geoscience is a unique stem field insofar as much of the data collection and skill development are practiced out in nature at locations around the world. the pis propose testing a strategy to overcome barriers in this context for ur students, as positive (or negative) experiences in field settings have profound impacts on recruitment and retention. this project will facilitate training and assessment of approximately 80 academic allies and measure the effect of that training on allies as well as hundreds of majority and ur students. the expectation is that the training will produce a secondary effect: academic allies role model effective behaviors to all of their students and faculty networks, creating a ?train-the-trainer? ripple effect. the pis will use academic field trips as a vehicle for measurement, including multisource ratings, applying 360-degree-type ratings typically collected in performance appraisals to this setting. deliverables include an experimental, longitudinal (over time), and multisource analysis of the allyship program and its improvement of allyship-related attitudes and behaviors, as well as its impact on the performance of ur students. these results will inform research efforts regarding the effectiveness of implemented strategies, and the materials and procedure will be made open-source for maximum replicability. a capstone

conference will be used to disseminate findings to all participating allies and ur students, inform about methodologies that improve attraction and retention of ur groups in the geosciences, and expand ur networks. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Two-photon absorption engineering in laser diodes for ultrafast pulse generation

Awardee: University of Colorado at Boulder

Amount: \$273,362.00

Abstract: semiconductor lasers are one of the most impactful photonic technologies on the market, with applications ranging from communications to medicine. however, the amount of power that can be obtained from short pulses of light remains low, despite decades of research. the problem is due to physical constraints, which the project will address through an interdisciplinary effort combining emerging materials synthesis with advanced optical physics to create short pulses with power well beyond the current state of the art. this will enable significant advances in both scientific understanding and practical performance, and will yield sources ideal for applications ranging from laser radar for autonomous vehicle navigation to advanced microscopy. the project will further benefit society by integrating research results with education through courses, and into an online course that was launched as part of the university of colorado boulder's master of science in electrical engineering (an online master's degree). additional dissemination and engagement will occur through avenues ranging from undergraduate research opportunities, a **\*\*diversity\*\***, equity, and inclusion seminar series, ecee connects at the university of colorado boulder, as well as science events at the texas school for the deaf. nonlinearities like two-photon absorption limit semiconductor lasers in both the high power cw and ultrashort pulse arenas, constraining the

available peak powers, pulse widths, and pulse energies. for pulsed sources, dispersion compensation provides some improvement; however, less-compact alternatives, such as fiber and solid-state lasers currently offer vastly superior performance. this project will combine recent advances in crystal growth and optical laser pulse shaping techniques to solve these issues and dramatically advance the performance of semiconductor ultrafast sources. specifically. high-bandgap semiconductor cladding layers can now be epitaxially integrated with longer-wavelength gain media to reduce two-photon absorption by orders of magnitude. when coupled with a new pulse shaping mechanism and pulse stacking, it is anticipated that this approach will enable kw peak powers and femtosecond pulses on a chip-scale semiconductor platform. the impact of the project will be further enhanced through a number of engagements and outreach activities and undergraduate research opportunities. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: ADVANCE - Catalyst: AGREE: Self-Assessment of Gender, Racial, and Ethnic Equity in STEM Faculty at Bucknell

Awardee: Bucknell University

Amount: \$271,594.00

Abstract: the advance- catalyst: agree project will support a two-year self-study at bucknell university, a primarily undergraduate institution in rural pennsylvania, to identify any existence of systemic inequities and advancement barriers related to gender, race and ethnicity in stem faculty through an intersectional approach. informed by quantitative and qualitative data, the project aims to develop and implement a plan to remove such barriers, solidify evidence-based best practices that support faculty success, establish a review mechanism that allows frequent reflection and improvements in institutional policies, build a supportive community where all members of bucknell

enjoy equitable resources and opportunities, thus extending the advance network, and produce generalizable strategies to extend the impact from this project to all faculty on bucknell campus and those at institutions similar to bucknell. this project will bring significant insights into issues facing women and underrepresented minority (urm) faculty that are unique to stem disciplines and in a primarily undergraduate institution that strives to enhance **\*\*diversity\*\*** in students, faculty and staff.

the advance- catalyst: agree project aims to uncover systemic inequities centered around recruitment, retention, and promotion processes facing women and faculty members underrepresented in stem disciplines. the project adopts an intersectional approach to collect quantitative and qualitative data from faculty through questionnaires and focused small group interviews followed by comprehensive analysis. the project will investigate factors that are unique at different career stages such as pre-hiring recruitment, tenure-review, and promotion and advancement to track the career progression of faculty of different genders and racial/ethnic backgrounds. the comprehensive self-study is expected to bring insights into addressing the historical and emerging barriers to equity and inclusion facing women and faculty who are underrepresented minorities in stem. the outcomes of the self-study will enable the institution to improve strategies to support and retain more women and underrepresented minorities in all disciplines. the implementation of these strategies will also provide generalizable practices to liberal arts institutions. the nsf advance program is designed to foster gender equity through a focus on the identification and elimination of organizational barriers that impede the full participation and advancement of diverse faculty in academic institutions. organizational barriers that inhibit equity may exist in policies, processes, practices, and the organizational culture and climate. advance "catalyst" awards provide support for institutional equity assessments and the development of five-year faculty equity strategic plans at an academic, non-profit institution of higher education. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: STEPP-NET: Steppe Parasite Networks

Awardee: University of North Carolina Greensboro

Amount: \$271,399.00

Abstract: this project focuses on collecting and describing mammals and their tapeworm and flea parasites from the grasslands of central asia. these parasites are highly diverse and ecologically important groups, and many are sensitive indicators of ecosystem quality; further, the parasitic infections they cause can have major negative impacts on wildlife. they also can play an important role in transmitting diseases from wild to domesticated species, and also to humans. however, knowledge of the **diversity** of parasite species, their geographic distributions, and the precise hosts they occur on and in remains highly fragmentary for much of the world. central asian mammals and their associated parasites are particularly highly imperiled but also little studied. this project will collect new material and study how tapeworm and flea parasites from the region evolve in conjunction with their mammalian hosts; it will also consider how the hosts and parasites have responded to various ecological changes across the region. this work is extremely time-sensitive, with many central asian ecosystems on the cusp of major land use change as economies shift and major construction occurs in the region. numerous specimens will be collected, and these will serve as a repository of parasite **diversity** useful for assessing how future global change influences the distribution of parasites and their hosts. this may ultimately improve public health outcomes. the work will also involve training the next generation of early-career stem researchers for careers in bio**diversity** science. the stepp-net project will rapidly advance discovery and description of species **diversity**, host associations, and community assembly, in two mammal-associated macroparasite clades - fleas and cestodes - across the vast grasslands of central asia. this region is a prototype for exploring host-parasite dynamics and spillover in response to human activity; historically, as a conduit for ancient silk road trade routes, and, currently, from intensifying land use changes and construction. stepp-net leverages existing museum specimens, new expeditionary

collections in mongolia and kazakhstan, and genomic analyses of hosts and parasites to advance knowledge of species boundaries, environmental and host niche breadth, and the exploration of novel host interfaces by focal parasite clades in response to global change pressures. a key outcome of stepp-net will be an extended specimen network for central asia, in which mammal and parasite specimens are durably linked to derived data and immediately useful in global bio\*\*diversity\*\* studies and public health initiatives. the project also creates opportunities for stem graduate and undergraduate students to participate across the spectrum of modern bio\*\*diversity\*\* science, from international fieldwork to specimen curation and digitization, genomics, and integrative taxonomy. it will build out this community of early-career stem researchers even further by developing undergraduate and graduate educational modules that are implemented across our institutions and hosted online for broader bio\*\*diversity\*\* literacy. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Trace Elements in Pyrite?Validation and Calibration of a Novel  
Paleoenvironmental Proxy

Awardee: University of California-Riverside

Amount: \$267,389.00

Abstract: life in the oceans is often limited by the availability of nutrients, such as nitrogen and phosphorus. other elements occurring in far lower abundances are also bioessential and potentially limiting?particularly trace metals such as iron and molybdenum. these metals are co-factors in many biological processes, and their distributions through time and space are strongly coupled to oxygen levels in the oceans; weathering of the continents; evolving atmospheric composition; and biological evolution. all of these factors tie intimately to climate change as a critical driver and consequence of metal cycling on land and in the oceans. yet, despite extensive study of metals in modern and

ancient oceans, basic gaps remain in our knowledge because of inadequate testing of certain chemical methods, particularly in the modern oceans. these methods, once refined, would allow for more confident exploration of a vast array of past conditions at earth's surface?far beyond those seen today. from that reinforced vantage, researchers can begin to imagine more rigorously and comprehensively what may lie in our future. one of the most promising methods for "time travel" through earth's evolving oceans is elemental analysis of pyrite, an iron sulfide mineral common today and in the past that may provide easily accessible and highly preservable historical archives. surprisingly, despite the advantages that may lie with this approach and hints of success already, no previous effort has attempted to validate and calibrate the pyrite tracer in modern oceans where present environmental conditions, local and global, can be tied directly to the composition of the mineral. this study is the first comprehensive investigation of these relationships in modern systems, strengthened by targeted experiments and novel analytical techniques. the principal expected outcome is an improved understanding of the controls and consequences of change at earth's surface as expressed in evolving ocean chemistry?past, present, and future?and the cause-and-effect relationships with co-evolving life. many studies are now using a technique called laser ablation-inductively coupled plasma-mass spectrometry (la-icp-ms) to measure trace metal contents of pyrite as a tracer for past marine conditions, and the initial results are encouraging. that said, there is still little mechanistic understanding of how and when trace elements are incorporated into pyrite and how these patterns and controls vary across environmental gradients. these uncertainties weaken their utility. the relationships among local controls and the capture of potentially global signals remain largely unknown. thus motivated, this study is designed around a two-pronged approach: (1) sampling in five classic, well-studied modern marine environments with a well characterized **\*\*diversity\*\*** of primary environmental conditions and (2) complementary, carefully conceived laboratory simulations designed to provide unprecedented insight into the mechanisms of trace metal uptake by iron sulfide minerals and their sensitivity to environmental backdrops. the ultimate goal is to expose the strengths and weaknesses of the proxy and best practices while

revealing new opportunities, such as the possibility of tracking the availability of bioessential trace metals in the ancient deep biosphere. plans include analyzing pore waters and sediments from diverse settings in modern oceans and interpreting those data within the framework of experimental results to reveal how trace metal content scales with conditions in the surrounding environment. the utility of the approach will be explored further using novel, highly sophisticated analytical methods applied at high resolution to characterize experimental and natural samples. this will be the first systematic study that correlates pyrite metal contents with metal availability in surrounding fluids and relates such data more generally to the wide range of environmental parameters and proxies often included in studies of earth's ancient biosphere. the impacts of this study will extend broadly through outreach opportunities targeting middle and high school students and ucr undergraduates placed in the lyons lab, while championing **\*\*diversity\*\*** and inclusion at all levels. that community footprint will be expanded through a recurring public lecture series and an on-campus science festival presented entirely in spanish, among other already tested community-directed efforts. at cmu, plans include a geochemical study at two middle schools in flint (mi) emphasizing water quality and use of those data to construct a new, much-needed community-driven water quality database for flint. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: EAGER: Elevating and empowering Hispanic/Latinx voices through video: Reducing barriers in academia and building an ecosystem for success in the Earth system sciences

Awardee: University Corporation For Atmospheric Res

Amount: \$266,162.00

Abstract: this nsf gold-en eager project aims to create a culture of belonging, equity, access, **\*\*diversity\*\*** and inclusion in the earth system sciences by building a network of support for minoritized groups that spans from their families to the university community to professional

societies. as our society is tasked to work on increasingly complex and urgent earth system challenges, geoscience and related fields are as important as ever. yet, the geosciences are one of the least diverse stem fields and there has been little improvement over the last 40 years. furthermore, the geoscience careers are less visible in some communities compared to other stem professions, resulting in careers in the geosciences being not well known or not perceived as viable careers. to solve current socio-environmental issues, marginalized voices must be brought in and elevated in equitable and culturally appropriate ways. this is particularly true for the hispanic/latinx community, the fastest growing minoritized group in the united states. this project will work with hispanic/latinx students and scientists in the earth system sciences to develop a foundation for engaging their families, strengthen a network for hispanic/latinx students and scientists in earth system sciences, and build a sustainable network of academic institution leaders to co-create an inclusive environment for hispanic/latinx students, scientists, and families. this project will foster a framework that will be expanded in the future for culturally appropriate engagement of other underrepresented communities and their families in the geosciences. three techniques will be employed to elevate the voices of hispanic/latinx communities, to increase the knowledge of careers in the geosciences, and to empower conversations between the latinx/hispanic community and the university system: 1) storytelling through film to strengthen and build upon existing culturally relevant science communication and storytelling skills of hispanic/latinx participants; 2) highlighting the experiences of hispanic/latinx students, scientists, and their respective families to increase knowledge of geoscience career opportunities; and 3) conversations between hispanic/latinx participants with university community leaders to elevate the understanding of challenges faced by hispanic/latinx students and scientists as they pursue geoscience careers. through the use of narrative storytelling and listening sessions, the project goals are: 1) to build an ecosystem for hispanic/latinx students to pursue geoscience careers with the support of their families, 2) to feel a sense of inclusion of hispanic/latinx people in academia in their pursuit of geoscience education and careers, 3) and increase retention through a sense of belonging in these fields with the support of

the university community leaders. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: OCE-PRF: Effects of increasing temperature and ultraviolet radiation on copepod mitochondria along a latitudinal gradient

Awardee: Auburn University

Amount: \$263,705.00

Abstract: this award is funded in whole or in part under the american rescue plan act of 2021 (public law 117-2). our understanding of the mechanisms by which organisms respond to climate change is incomplete. as temperature and ultraviolet (uv) radiation increase, the ability of organisms to survive and reproduce depends on their ability to adapt to changes in the environment. the ability of mitochondria to produce energy in animals is influenced by the movements (i.e., behavior) and structure of these organelles. the ability of mitochondria to produce energy directly impacts animal performance, including survival and reproduction. in turn, the behavior and structure of mitochondria are influenced by the environment. this work aims to: 1) determine if uv radiation influences mitochondrial behavior and structure in natural populations of a marine organism, copepods, in the same manner observed in a laboratory setting, 2) determine if temperature affects mitochondrial behavior and structure in natural populations of copepods, and 3) determine how much the behavior and structure of mitochondria change in the short-term versus the long-term in response to changing environmental conditions. the results of this study will transform our understanding of how environmentally important organisms such as copepods may respond to climate change. in collaboration with the auburn university college of science and mathematics, this work will advance the education and science literacy of students in the state of alabama. the pi will develop several outreach programs to fit the pre-existing infrastructure at auburn university to increase the science

involvement and literacy for 1st ? 6th and 11th ? 12th grade students and interact with the community to discuss the importance and relevance of the research for the general public. these outreach initiatives will involve hands-on participation of students in learning about the scientific process, mitochondria, copepods, and the use of microscopes in scientific research. the general public will gain insight into the importance of the research in understanding the impact of climate change on one of our world's most abundant aquatic organisms. the goal of this work is to integrate observational fieldwork and experimental lab work to further understand the impact of environmental stressors on the physiological ecology of copepods along the west coast of north america. this work aims to fundamentally change our understanding of the mechanisms by which pervasive zooplankton such as copepods can potentially respond to climate change. the pi will collect data on copepods from populations in san diego, ca, battle rock, or, and friday harbor, wa. he will measure their metabolic rate at the point of highest uv exposure and temperature during the day and lowest uv exposure and temperature at night. after measuring metabolic rate, the same copepods will be fixed for transmission electron microscopy (tem) to quantify mitochondrial behavior and morphology, including density of the inner mitochondrial membrane, proportion of inter-mitochondrial junctions, mitochondrial density, and mitochondrial area and aspect ratio. additional copepods from these populations will be shipped to auburn university to establish lab populations under the same temperatures and uv radiation as measured in the field. mitochondrial phenotypes quantified via tem and metabolic rate will be measured following reciprocal transplant experiments in the lab to determine the extent that differences in mitochondrial phenotype are due to environmental variation versus evolved, genetic differences in response to temperature and uv radiation. in collaboration with oregon state university, transcriptomics will be completed under the transplant experiments to identify the up/downregulation of genes that may be associated with mitochondrial behavior and morphology to maintain metabolic rate differently between the three populations. copepods are a cornerstone of biological **diversity** in aquatic ecosystems. as such, it is imperative that we begin to understand the physiological responses of these organisms so that we

may better understand the impact of climate change on marine populations. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Theory-Grounded Guidelines for Solver-Aware System Architecting (SASA)

Awardee: George Washington University

Amount: \$263,492.00

Abstract: the objective of this project is to advance the scientific understanding of a new paradigm of system architecting in engineering, referred to as solver-aware system architecting (sasa). sasa actively considers the capacity of talent and expertise from outside organizational boundaries (e.g., gig workers, crowd) during the formulation phases of the system design process. this research hypothesizes that the joint consideration of system architecture, diverse external solvers, and contract mechanisms, can significantly improve system design outcomes. the research will result in new theory and best practices for when and how to incorporate novel sources of effort into complex systems design, which has positive implications for workforce management. with an explicit focus on translation to practice, the guidance generated by this work has the potential to make a tangible impact on how system architecting is practiced, and the way organizations engage with outside and non-traditional solvers, which promises greater effectiveness and efficiency in technical business operations. the theoretical innovations will be reduced to practice in the form of actionable guidelines relating sasa principles to design outcomes. additional deliverables of this project include a set of educational tools to educate students and industry practitioners on sasa. if successful, the research will result in scientific foundations for the paradigm shift from traditional approaches to system architecting, which assume traditional players bounded by organizational boundaries, to more open innovation approaches for complex systems design. the research will establish a firm

scientific foundation consisting of (i) socio-technical theory for architecting complex systems; (ii) computational models of open innovation processes for systems design and computational methods for designing contractual mechanisms for sasa; and (iii) empirically-validated design guidelines to support practitioners of sasa. the research will extend the frontier of knowledge in systems engineering research and practice by shedding light on the linkages among innovation processes, designer knowledge, systems architecture and contractual structures. the resulting educational tools will have a direct impact on student learning about system architecting. the tools will be tested at the pis? institutions and then made freely available to other members of the engineering design and systems engineering (edse) community. the focus on leveraging non-traditional contributors has implications for broader societal goals around **diversity** and inclusion, broadening participation in stem through new avenues for access, and eliminating barriers to traditional professional practice. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Using Tutorial-Based Active E-Learning to Broaden Participation and Enhance Scientific Computing Skills in a Seismology Context

Awardee: Miami University

Amount: \$262,507.00

Abstract: this project aims to serve the national interest by improving computational thinking and scientific computing skills of advanced undergraduate students. it will do so by developing a large-enrollment, asynchronous, open access, online computational workshop. such training is important to ensure that future scientists develop the knowledge and skills they need to tackle computer- and data-intensive scientific problems of national importance, such as climate change. this project will provide more than 1200 advanced undergraduates with computational training in a seismological context. the training will build on and refine a pilot tutorial-based, active e-learning

experience called the seismology skill building workshop. the project also aims to generate a more successful, inclusive, and satisfying online learning experience that can be exported to other stem disciplines. because the workshop offers advanced coursework online without fees or prerequisites, it is likely to increase the participation of diverse undergraduates and other learners in computing. in fact, based on data from the pilot workshop, this project will reach many students from communities that have been disproportionately impacted by the covid-19 pandemic. through its research efforts, the project intends to increase understanding about how diverse groups of students engage with and benefit from the tutorial-based active e-learning approach. by identifying workshop features that attract diverse audiences and promote retention, learning, and satisfaction, the project can also define a framework that other stem communities can use to develop similar technical training efforts.

a preliminary seismology skill building workshop was offered in 2020 by the incorporated research institutions for seismology, an nsf-funded university consortium that operates the seismology community data and equipment facility. the pilot workshop was launched in response to the covid-19 pandemic and reached more than 700 students, many more than anticipated and with higher **\*\*diversity\*\*** than typical in-person computing courses. through the pilot workshop, the project team identified challenges and gathered data about workshop effectiveness. this project will investigate the resulting research questions, which are important within and beyond seismology: 1) to what extent does this online scientific computing training model enhance participant learning and behavior? 2) what are the key influences on retention and performance for advanced undergraduates in the online scientific computing training model and can new interventions improve efficacy? 3) to what degree do the elements of the tutorial-based active e-learning approach contribute to learning? 4) how can the value of the seismology skill building workshop and its positioning within the seismology learning ecosystem be optimized to ensure sustainability? these questions will be addressed through a multi-year, mixed methods research investigation that includes development of instruments for summative assessment of computational thinking and programming within a disciplinary context, improved characterization of assignment question types

to examine performance trends, and correlation analysis of participant activity and performance data. expert reviews of the curriculum and community focus groups will be conducted to ensure sustainability of the seismology skill building workshop. the nsf iuse: ehr program supports research and development projects to improve the effectiveness of stem education for all students. this project is in the engaged student learning track, through which the iuse program supports the creation, exploration, and implementation of promising practices and tools. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Illuminating the characteristics, causes, and paleoclimatic importance of the Mid-Cenozoic Loess in the Western USA

Awardee: University of Connecticut

Amount: \$260,818.00

Abstract: loess deposits consist of fine-grained, windblown sediments and contain critical information about continental aridification processes that are key to understanding biotic evolution and climate change. this project integrates field data collected from loess deposited ~37-30 million years ago in wyoming, nebraska and montana, laboratory analyses, and paleoclimate simulations to understand the nature, causes, and paleoclimatic importance of these loess deposits. the research will advance stem **\*\*diversity\*\*** by supporting a two-day geocamp for historically underrepresented high-school students from east texas. in addition, this project will promote further development of the high-resolution community earth system model to be used to better understand ancient climate changes. this project will include field sedimentological observation and lab analyses of bulk sediment and quartz grain-size, quartz surface morphology, detrital and high-precision zircon u-pb geochronology to study the ancient loess deposits in wyoming, nebraska and montana, usa. these proxy data will constrain the extent, timing, pattern and characteristics of the loess; and determine

sediment provenance and sediment recycling mechanisms. these proxy data will be integrated with a coupled atmosphere-land model to simulate changes of regional climate and vegetation induced by topography changes, global climate cooling, glaciation and shoreline regression to understand the cause and climate significance of the loess. in addition to gaining fundamental understanding of the loess deposits, the project will shed light on 1) the influence of climate change on biotic evolution at the eocene-oligocene transition (~34 million years ago); 2) the validity of different models of surface uplift in the western usa; and 3) the potential positive climate feedback of enhanced mineral dust emissions on global cooling at the transition. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Amount: \$260,818.00

Abstract: loess deposits consist of fine-grained, windblown sediments and contain critical information about continental aridification processes that are key to understanding biotic evolution and climate change. this project integrates field data collected from loess deposited ~37-30 million years ago in wyoming, nebraska and montana, laboratory analyses, and paleoclimate simulations to understand the nature, causes, and paleoclimatic importance of these loess deposits. the research will advance stem **\*\*diversity\*\*** by supporting a two-day geocamp for historically underrepresented high-school students from east texas. in addition, this project will promote further development of the high-resolution community earth system model to be used to better understand ancient climate changes. this project will include field sedimentological observation and lab analyses of bulk sediment and quartz grain-size, quartz surface morphology, detrital and high-precision zircon u-pb

geochronology to study the ancient loess deposits in wyoming, nebraska and montana, usa. these proxy data will constrain the extent, timing, pattern and characteristics of the loess; and determine sediment provenance and sediment recycling mechanisms. these proxy data will be integrated with a coupled atmosphere-land model to simulate changes of regional climate and vegetation induced by topography changes, global climate cooling, glaciation and shoreline regression to understand the cause and climate significance of the loess. in additional to gaining fundamental understanding of the loess deposits, the project will shed light on 1) the influence of climate change on biotic evolution at the eocene-oligocene transition (~34 million years ago); 2) the validity of different models of surface uplift in the western usa; and 3) the potential positive climate feedback of enhanced mineral dust emissions on global cooling at the transition. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: P2C2--MADagascar Caves And Paleoclimate II (MADCAP II), Continuing Study of Climate Variability in the Southern Hemisphere of the Western Indian Ocean

Awardee: Massachusetts Institute of Technology

Amount: \$258,922.00

Abstract: the research team aims to build upon previous research using speleothems from caves in northwest and southwest madagascar to reconstruct late pleistocene and holocene climate from a southern hemisphere tropical site and to examine the role of climate in the ongoing alteration of the island's ecosystems. using previously collected samples, the researchers plan to construct high-resolution (decadal) multiproxy climate records from the last glacial maximum (26,000 years ago) to the present from high-resolution (near annual resolution) analyses for periods of particular climatic interest (e.g., the 4.2 ka event, younger dryas). the researchers will extract organic matter from the speleothems across an interval of marked change in speleothem delta carbon-13 and

measure biomarker concentrations and the same to test a newly developed ?subsistence shift hypothesis? for the disappearance of madagascar?s megafauna. speleothem fluid inclusion water isotopes, combined with carbonate oxygen isotopes, will be examined as a tool to estimate paleotemperatures over the past 117,000 years for southwest madagascar and the past 26,000 years for northwest madagascar. the goal of the project is to produce long, high resolution records of climate from the southern hemisphere tropics. these data will aid in understanding the influences of inter tropical convergence zone (itcz) migration, western indian ocean sea-surface temperature (sst), and regional precipitation. in particular the project will investigate whether the indian ocean monsoon in the northern versus southern hemispheres vary in or out of phase at various timescales and test current hypotheses on tropical rainfall variation. the potential broader impacts include the integration of science across the fields of paleoclimatology, anthropology, and biology to provide background climate data needed for interpreting the impact of climate on a variety of fossil communities of the past. the research team will produce educational materials and exhibits prepared for a general audience to heighten public awareness of tsimanampesotse national park?s natural history, bio\*\*diversity\*\*, and extinction events. the project will help develop a better understanding of the causes of decadal-scale climate variability which can aid in forecasting possible changes in rainfall in a country that experiences severe drought and flooding on inter-annual time scales and relies on subsistence farming for survival. this project includes supporting an early career female post-doctoral scholar in the united states and collaboration with malagasy scientists and students as well. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: MRI: Acquisition of Electroencephalography Equipment for the Study of the Neuroplasticity of Language and Cognitive Processes in Bilingualism and Multilingualism

Awardee: California State University, East Bay Foundation, Inc.

Amount: \$258,811.00

Abstract: this award is funded in whole or in part under the american rescue plan act of 2021 (public law 117-2). the major research instrumentation grant supports the acquisition of a state-of-the-art electroencephalography (eeg) system (actichamp plus 64-channel active electrode system, brainvision llc) that will be used to non-invasively measure electrical activity generated by populations of neurons with very precise timing accuracy. the acquisition of this eeg equipment will permit cross-disciplinary collaborations among faculty at several institutions throughout california to study the neural processes that support language and cognitive processes in bi-/multilingual adults, and how these processes change across the lifespan in response to new experiences or injury (i.e., neuroplasticity). interdisciplinary approaches are critical to the advancement of our understanding of the complex mechanisms in the mind and brain because the complexity of these processes requires perspectives from developmental science, cognitive science, language science, cognitive aging, and neurolinguistics, among others. the new equipment will be used to train a diverse student population in cognitive neuroscience research methods and the study of the neuroplasticity of communication, thereby promoting access to careers in basic science, clinical research, and applied settings. california state university east bay is a hispanic-serving and asian american & pacific islander-serving institution, drawing first-generation and minority students from the diverse bay area community who are historically underrepresented in these fields. despite recent advances in the basic neural changes associated with experience-dependent brain plasticity, our understanding of the structural and functional neural plasticity associated with language and cognitive functioning across the lifespan, and in response to injury, is still limited. the study of bilingualism and multilingualism provides a unique window into these processes; managing two language systems and flexibly switching between them engages the linguistic and cognitive control systems in unique ways, shaping the neural structures that underlie language and cognition. research activities enabled by the eeg equipment include investigating neural activity associated with a) second

language learning in adulthood and the regulation of the native language, b) formal instruction in a heritage language, c) language mixing practices in dense bilingual communities, d) the involvement of the left and right cerebral hemispheres in bilinguals? judgments of learning, e) the preservation of cognitive abilities in aging bilinguals, and f) the connectivity of various brain regions associated with language and cognitive processing in bilinguals with aphasia, a language disorder resulting from neurological damage. moreover, by investigating individual differences among bilinguals in factors such as age of second-language acquisition, language proficiency, and language use patterns, the researchers can explore how the brain responds to diverse language experiences in childhood and adulthood. these projects investigate the neural underpinnings of language and cognition across a broad spectrum of adults across the lifespan, both neurologically healthy and those with neurological damage. eeg allows us to study the online neural processes that lead to the language and cognitive behaviors characteristic of different language users, whose **\*\*diversity\*\*** is critical for developing generalizable theories of language and cognition. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Theory-Grounded Guidelines for Solver-Aware System Architecting (SASA)

Awardee: Purdue University

Amount: \$258,678.00

Abstract: the objective of this project is to advance the scientific understanding of a new paradigm of system architecting in engineering, referred to as solver-aware system architecting (sasa). sasa actively considers the capacity of talent and expertise from outside organizational boundaries (e.g., gig workers, crowd) during the formulation phases of the system design process. this research hypothesizes that the joint consideration of system architecture, diverse external solvers, and contract mechanisms, can significantly improve system design outcomes. the research will result in new theory and best practices for when and how to incorporate novel sources of effort into complex systems design, which has positive implications for workforce management. with an explicit focus on translation to practice, the guidance generated by this work has the potential to make a tangible impact on how system architecting is practiced, and the way organizations engage with outside and non-traditional solvers, which promises greater effectiveness and efficiency in technical business operations. the theoretical innovations will be reduced to practice in the form of actionable

guidelines relating sasa principles to design outcomes. additional deliverables of this project include a set of educational tools to educate students and industry practitioners on sasa. if successful, the research will result in scientific foundations for the paradigm shift from traditional approaches to system architecting, which assume traditional players bounded by organizational boundaries, to more open innovation approaches for complex systems design. the research will establish a firm scientific foundation consisting of (i) socio-technical theory for architecting complex systems; (ii) computational models of open innovation processes for systems design and computational methods for designing contractual mechanisms for sasa; and (iii) empirically-validated design guidelines to support practitioners of sasa. the research will extend the frontier of knowledge in systems engineering research and practice by shedding light on the linkages among innovation processes, designer knowledge, systems architecture and contractual structures. the resulting educational tools will have a direct impact on student learning about system architecting. the tools will be tested at the pis? institutions and then made freely available to other members of the engineering design and systems engineering (edse) community. the focus on leveraging non-traditional contributors has implications for broader societal goals around **\*\*diversity\*\*** and inclusion, broadening participation in stem through new avenues for access, and eliminating barriers to traditional professional practice. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: SBIR Phase I: Developing Technology for Stimulating the Herd Instinct of Livestock to Improve Environmental Impact

Awardee: RANCHCHECK INC.

Amount: \$256,000.00

Abstract: the broader impact of this small business innovation research (sbir) phase i project is to help restore grassland ecosystems and reduce net greenhouse gas emissions from livestock by

developing technology to stimulate the herd instinct of livestock. grassland ecosystems have been shown to benefit from large herds of animals that promote water absorption and replenish important nutrients. however, most livestock in the western united states are currently scattered in large pastures and allowed to roam individually. this project aims to develop and test low-cost ear tags which use audio and electrical stimulation to reinforce the natural herd instinct of individual animals when they stray from the group. high stock density/low duration grazing has demonstrated the potential of reducing livestock greenhouse emissions and turning rangelands into a net carbon sink. higher vegetation **\*\*diversity\*\***, more water absorption, reduced erosion, and more wildlife habitat are just some of the expected ecological benefits of this technology. this technology could also facilitate more efficient and cost-effective ranch management. the risk of livestock theft will be reduced, and the need for fences would decrease since the migratory instincts of livestock work best on larger land areas. this sbir phase i project will develop and test a novel approach of stimulating the herd instinct of livestock rather than geographically confining them. key to the implementation of this approach is the additional innovation of a unique and low-cost strategy to use ear tags with low-power radiofrequency (rf) transceivers to calculate herd proximity from an accumulation of individual distance estimates. this technology will use a highly integrated system using an ear tag attached to each animal in the herd. each tag will use a low power rf transceiver to periodically send brief signals to the other tags in the herd. the tags will use signal strength measurements to calculate their own approximate distance to every other tag. each tag will then use an algorithm to determine whether it is within an appropriate proximity to the rest of the herd. if an animal begins to stray from the herd, the tag will give an audio alert potentially followed by electrical stimulation to encourage the animal to rejoin its peers. the capability of holding a herd at a density from 10,000 to 1,000,000 pounds per acre will be a key metric of success. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: SBIR Phase I: Field Demonstration of Ship Hull Inspection with a Fleet of Unmanned Underwater Vehicles

Awardee: BERKELEY MARINE ROBOTICS INC.

Amount: \$256,000.00

Abstract: the broader impact of this small business innovation research (sbir) phase i project is to protect marine ecosystems against invasive species and to help the shipping industry reduce its greenhouse gas (ghg) emissions. marine invasive species are considered to be one of the greatest threats to marine and coastal bio\*\*diversity\*\* worldwide, second only to habitat loss. keeping the oceans healthy is essential to preserve the employment, development and growth of the ocean economy. this is particularly relevant in the united states, where the marine economy contributes nearly \$400 billion to the nation's gross domestic product with 40 percent of the population living in coastal counties. one of the main vectors for the transfer of marine invasive species is the biofouling on ship hulls, described as the undesirable accumulation of microorganisms, plants, algae and animals on the submerged hull. a second impact of biofouling is to increase the drag forces on the hull, resulting in an increase of the ship's fuel consumption and ghg emissions in the atmosphere. this project advances a system for in-water inspection of ship hulls with a fleet of unmanned underwater vehicles (uuv's). the automated underwater inspection system will provide maritime stakeholders with biofouling data to optimize hull cleaning schedules, validate compliance with regulations, thereby improving ship performance and ecosystem health. this project develops a system leveraging a uuv fleet that forms an arch operated from a vessel (e.g. power boat, crew vessel) located at one of the arch's extremities. it can inspect hulls as ships enter or leave ports without having to be immobilized. the uuv's exchange data wirelessly between each other and with the surface, enabling autonomous coordinate inspections without tethers but under human supervision. an advanced positioning system and control scheme will be implemented to enable accurate localization without gps and precise operation in the vicinity of the hull. this project will

conduct in-water experiments to validate the performance of the positioning system and control scheme. the outcome of the project will be a proof-of-concept where a fleet of two uuv's inspect the hull of a vessel, demonstrating that the inspection system is fast, practical and repeatable. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: SBIR Phase I: Microbe-based scaffold for the generation of structured cell-based meat

Awardee: NOVEL FARMS, INC.

Amount: \$256,000.00

Abstract: the broader impact of this small business innovation research (sbir) phase i project is to address challenges of animal farming through cell-based meat production. approximately 30% of the earth's surface, 70% of all arable land, and 29% of the global freshwater supply is dedicated to animal farming. livestock is responsible for 18% of global greenhouse gas emissions and is a major threat to bio\*\*diversity\*\*. 70% of all antibiotics used in the united states are used on farm animals and contributes to the emergence of antibiotic-resistant bacteria. cell-based meat development is estimated to generate significant reductions in greenhouse gases and use of land, water, and energy, as well as antibiotics in meat production. the proposed project aims to develop novel technologies that will accelerate cell-based meat development. the proposed project develops a novel scaffolding material for the generation of animal tissue, specifically skeletal muscle. the proposed project will ultimately advance current scientific knowledge on the mechanisms underlying tissue generation and elucidate the molecular principles governing cell adhesion, differentiation, and growth of animal cells during tissue development. key technical objectives include demonstrating that the proposed scaffold can be successfully customized to harbor any cell adhesion molecule of interest, and proving that a novel biomaterial can be adapted as a tissue-culture-grade reagent. fluorescence microscopy will be used to ascertain the extent of animal cell adhesion and growth on

the proposed scaffold. these studies will advance understanding of animal cell interactions with their extracellular milieu, and how environmental molecular properties and cues are tuned to influence de novo tissue development in vitro. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: SBIR Phase I: Climate analysis at scale through mapping biomass, water restoration, and soil carbon sequestration

Awardee: EARTHSHOT Labs PBC

Amount: \$256,000.00

Abstract: the broader impact/commercial potential of this small business innovation research (sbir) phase i project is to scale nature-based climate mitigation. the phase 1 project will create and manage comprehensive data sets and models representing the current and proposed future state of ecosystem health as measured by aboveground biomass growth in forests, the health and carbon sequestration in soils, and the restoration of groundwater in arid or otherwise degraded environments through the restoration of hydrological function. through its open source and community-oriented approach, the project intends to be a valuable resource for organizations mitigating loss of bio\*\*diversity\*\*, soil health, forest cover, and groundwater due to extractive land use practices. the information provided by this technology will be useful for landowners, governmental authorities, researchers, and financial institutions. the project will utilize recent advances in remote sensing, cloud compute infrastructure, and machine learning to predict the highest leverage land-based interventions for managing and enhancing the hydrological cycle, protecting forests and increasing reforestation efforts, and building soil health and resiliency through soil organic carbon sequestration. the highest impact water interventions will be determined using random forest algorithms improved through the use of soil models that include porosity, rates of

runoff, and texture. the forest-based interventions for conserving and increasing above-ground biomass will be based on historic land use change and disturbance regimes as monitored through satellite imagery and coupled with potential sequestration rates achieved through restoration and improved forest management. soil health and carbon sequestration modeling will be accomplished using historic soil sample data over an 80 year period and the associated environmental covariates in addition to research into rates of soil sequestration by land management type. this will enable the training of a random forest-based model to predict the highest impact land use interventions to enhance or restore soil organic carbon. these models will be combined to create an interactive land viewer. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: BENEATH THE FOUNTAINS: Shallow conduit processes and diversity in basaltic fissure eruptions.

Awardee: University of Hawaii

Amount: \$255,794.00

Abstract: mildly explosive eruptions?the most frequent manifestations of subaerial explosive volcanism on earth?broadly group into two styles: strombolian and hawaiian. the former is characterized by sequences of intermittent discrete explosions and the latter by sustained pyroclastic fountaining. explosive activity during the 2018 fissure eruption of k?lauea volcano (hawai?i) provided an exceptional opportunity to record a wide range of strombolian and hawaiian behavior (figure 1), thanks to the accessibility of the volcano and the wealth of data types collected throughout the event. this study address which processes in the plumbing system beneath the volcano ?drove? the great **\*\*diversity\*\*** in style and intensity of the 2018 explosive activity compared to previous, more consistent, fissure eruptions at k?lauea and elsewhere? k?lauea is an exceptionally active volcano and its eruptions pose constant challenges for management agencies

because the eruption sites are highly accessible and there is a need to balance the strong popular interest in viewing the eruptive activity against public safety (as seen in 2018). this balance requires critically on sophisticated knowledge of the volcano's current and immediately future behavior. there is both a public desire for better knowledge of the volcano's behavior and a need for improved forecasting of the likely course and footprint of all future eruptions. the observatory partner, usgs, has a federally mandated role to advise response agencies in hawaii and will transfer knowledge from the nsf-funded study to the bodies charged with risk management. this work involves exchange of material and ideas between institutions in the usa, and the united kingdom to the benefit of young researchers and students. the results will be widely disseminated via meetings and workshops, courses offered by the fema-funded national disaster preparedness training center, the internet and scientific publications and a planned virtual field trip to kilauea. the goal of this study is to link existing high-resolution observations of explosive basaltic fissure eruptions to the processes in the very shallow conduit that cause and shape them, focusing on the 2018 kilauea eruption as a case study. it will combine existing data derived from high temporal and spatial resolution videos with: (1) field measurements of five representative pyroclastic footprints, and laboratory characterization of the ejecta, (2) high-precision measurements of two-phase magma rheology, and (3) models tied to newly completed laboratory analog experiments to simulate outgassing patterns. this approach is expected to help identify patterns and precursors that accompany transitions in eruptive style, supporting risk management for communities on the flank of this very active volcano. this study will fundamentally improve our understanding of the dynamics of hawaiian and strombolian eruptions. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Digitization TCN: Extending Anthophila research through image and trait digitization (Big-Bee)

Awardee: California Academy of Sciences

Amount: \$255,400.00

Abstract: declining populations of bees impact plant-pollinator interactions in both natural and agricultural systems. while bees and other insects pollinate most wild plants, and are critical to sustain a large proportion of global food production, they are decreasing in both numbers and **\*\*diversity\*\***. our understanding of the factors driving these declines is limited because we lack sufficient data on the distribution of bee species, and on the behavioral and anatomical traits that may make them either vulnerable or resilient to human-induced environmental changes, such as habitat loss and climate change. fortunately, wild bees have been collected by researchers and deposited in natural history collections for over 100 years, retaining a wealth of associated attributes that can be extracted from specimen images. this project will digitally capture data and images from these historic specimens, develop tools to measure bee traits from these images, and generate a comprehensive bee trait and image dataset to measure changes through time. this will increase our understanding of specific traits that put bee species at risk of decline - a critical need for both sustaining our agricultural economy and the conservation of our natural resources. in addition, the large image datasets created by this project can be used for new artificial intelligence identification tools that will help improve our future pollinator observation and monitoring efforts. the big-bee thematic collection network (big-bee tcn) will create over one million high-resolution 2d and 3d images of bee specimens, representing over 5,000 worldwide bee species, including all of the major pollinating species of the united states. the big-bee network includes 13 institutions and partnerships with us government agencies. novel mechanisms for sharing image datasets will be developed and datasets of bee traits will be available through an open data portal, the bee library, for research and education. the big-bee project will engage the general public in research through community science via crowdsourcing trait measurements and data transcription from images. in addition, training and professional development for natural history collection staff, researchers, and university students in data science will be provided through the creation and implementation of workshops focusing on

bee traits and species identification. all data resulting from this award will be shared with and publicly available through the national digitized biocollections resource, idigbio.org. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Family Bereavement: Societal Prevalence, Patterning, and Consequences

Awardee: University of Southern California

Amount: \$254,788.00

Abstract: this project investigates family bereavement?the phenomenon of experiencing the death of a family member. extensive research has identified how economic and social hardship can contribute to an individual?s risk of death; yet we know less about whether the death of a family member can induce hardships for those bereaved. scientific efforts to understand family bereavement are highly relevant given the covid-19 pandemic?a global mortality event of historic proportions that has left millions of individuals grieving the abrupt death of relatives. this study offers a life course overview of family bereavement and its socioeconomic and health consequences. whereas past studies have focused on singular types of family loss, like parental death, this study considers multiple relatives. this allows clarification of the societal burden of different types of bereavement and their unique consequences for individuals. findings can inform programmatic efforts to address the effects of bereavement on population health, prosperity, and welfare. in addition to generating findings of high relevance to public health, this research supports **\*\*diversity\*\*** in science through the mentoring and training of students from historically under-represented groups. the first goal of the project is to identify the consequences of family bereavement by analyzing rich survey data on a cohort of 1,500 young adults. the data feature detailed family history information, including whether relatives are still alive and if not, how long ago they died, how old they were at the time of death, and whether they suffered from prolonged illness. these data are

used to analyze whether experiences of family bereavement influence young adults' wellbeing, including their mental and physical health and educational success. the second goal of the study is to use cross-national survey data on more than 3.7 million youth and 1.8 million adults to offer a comprehensive overview of the societal and life course patterns of family bereavement in more than 50 locations. by identifying the societal burden of family bereavement at the community, regional, and higher levels, and elucidating between-family and cohort differences in life course patterns of bereavement for multiple birth cohorts, the study offers foundational knowledge on family bereavement. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: GP-UP: Developing STEM Identity by Engaging URM Undergraduate Students in Research on Air Pollution in Chicago Communities

Awardee: Loyola University of Chicago

Amount: \$253,571.00

Abstract: this award is funded in whole or in part under the american rescue plan act of 2021 (public law 117-2). the geoscience learning community will help students from historically excluded communities build their stem identity through authentic research experience, mentoring, and introduction to geosciences careers. students will learn about air pollution, gain experience with instrumentation, practice computer programming and data analysis, and communicate scientific results by participating in real research with prosocial impact. this project addresses three geopath program goals: (1) increase the number and **\*\*diversity\*\*** of students in geosciences; 2) prepare students for geoscience careers; and 3) contribute to the evidence base for effective student engagement, learning, and retention in stem. the data collected through this project will be of sufficient quality to contribute to community discussions about how best to reduce air pollution and better protect public health, particularly within vulnerable communities. this project seeks to

employ several established evidence-based strategies for the success of students from historically excluded communities. a focus on student success in stem will include authentic collaborative undergraduate research experiences, sustained mentorship, and engagement in research with a direct link to community benefit. by combining authentic prosocial research and mentoring, the pis aim to build a sense of belonging, self-efficacy, and stem identity in two cohorts of students and help with their successful transitions to stem programs related to the earth sciences. this project specifically proposes to create geoscience learning community that engages undergraduate students from historically excluded communities in research to measure and attribute air pollution in two chicago neighborhoods that differ in socioeconomic status, demographics, and proximity to industrial facilities. the pis will recruit a cohort of undergraduate participants at loyola to join a research-intensive learning community each of year 1 and year 2 of the project. student participants will work closely with scientists and the community-based organizations to design and carry out research that addresses community concerns about air pollution. the project's aims are to 1) provide an applied, socially relevant research experience for student participants; 2) understand how particulate pollution in chicago varies over space and time; and 3) provide air quality data for community use. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Research Initiation: Understanding Impacts of Soft Robotics Curricula on Female Students Engineering Identity

Awardee: University of Illinois at Urbana-Champaign

Amount: \$253,122.00

Abstract: participation in k12 educational robotics is a common precursor to enrollment in engineering majors, however the gender gap in traditional pre-college robotics prevents equal

access to these disciplines. we believe soft robotics may create a new pathway for students from underrepresented groups to enter engineering majors. soft robots are those devices made from soft materials and flexible electronics enabling robots to more safely interface with humans and other living organisms. soft robotics presents an opportunity to introduce traditional engineering principles through a human-centered perspective with the potential to diversify engineering. this project will address two aims. first, this project aims to understand changes in the engineering identity of middle and high school-aged female students after having engaged in soft robotics projects in their science classes. second, this project aims to introduce the principal investigator to engineering education research, catalyzing a new research enterprise focused on access to engineering and educational robotics. the research team will utilize existing relationships with local schools to deliver a previously piloted soft robotics curriculum and study student experiences. implementation will include a one-week, hands-on robotics short course for about 200 middle and high school students local to the university of illinois urbana-champaign. to date, the lack of representation of women in mechanical and electrical engineering is well-documented. however, successful pathways for women to these majors are understudied. agency beliefs have been a useful lens for understanding how women do enter some engineering majors, such as bioengineering. the mentor-mentee research team will leverage a mixed methods approach to explore soft robotics as a new pathway to engineering critical engineering agency will be a framework through which to understand the student experience. the research team will use surveys and interview instruments to help answer the overall research question: how can a soft robotics implementation impact high school students? attitudes and self-beliefs, and therefore serve as a strategy to recruit female students to traditionally male-dominated engineering majors? prior to the activity, students will be surveyed using engineering identity and agency belief measures. after implementation, students will complete a post-survey and the research team will interview select students to understand how the activities impacted their engineering identity. the result of this collaborative research project will be an analysis of the elements of pre-college soft robotics curriculum that may lead to diverse recruitment

in engineering. education of local stakeholders in standards-based soft robotics curriculum opens the door for further engagement in our local community. dissemination of research results will enable broad adoption. findings from this study will pave the way for increased representation of women and underrepresented minorities in engineering at the college level and in the engineering workforce, contributing to a **diversity** of solutions to society's critical challenges. soft robotics curricula have the potential to prepare a diverse generation of engineers and reduce the barrier to entry not only for girls, but other students from underrepresented groups. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: REU Site: Multidisciplinary Underground Science at the Sanford Underground Research Facility

Awardee: Black Hills State University

Amount: \$251,244.00

Abstract: this award is funded in whole (or in part) under the american rescue plan act of 2021 (public law 117-2). black hills state university (bhsu) will host a 10-week research experience for undergraduates (reu) program centered on underground science at the sanford underground research facility (surf). this program will recruit six undergraduate students each year to participate in exciting underground research projects as well as professional development, social and outreach activities. underground science offers possibilities for interdisciplinary research across a variety of disciplines including physics, chemistry and biology. recruitment efforts of the bhsu reu site will be especially focused on american indian, female and community college students. surf hosts and performs some of the most important physics experiments of our time, searching for evidence of dark matter and investigating the physics of neutrinos. students the students will particularly be offered the opportunity to engage in research related to these experiments by assaying materials for

radiopurity measurements, helping to characterize the Iz detector and testing the chemical purity of noble gases. additionally, research at surf is being carried out in the study of life deep underground, with applications to medicine and astrobiology, in particular in the **\*\*diversity\*\*** of microbial environments and in the isolation of novel microbes. complementary chemistry research will also be performed to determine the local environment in which these microbes live. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: MCA: Advances in Understanding the Biogeochemical Evolution of Serpentinites (AUBES)

Awardee: University of Rhode Island

Amount: \$250,644.00

Abstract: this project is jointly funded by the division of earth sciences' mid-career advancement (mca) program and the established program to stimulate competitive research (epscor). microbial life has refined the fine-scale chemistry of minerals for billions of years of earth history, leaving complex, durable records of metabolic activity behind. fracture networks in rocks preserve a durable mineral record of these ancient processes, often touching questions related to the origin and early adaptive strategies of rock-hosted, microbial life on earth. in this project, iron-rich rocks (also high in chromium, nickel, and other metals) from earth's mantle, collected through scientific drilling in northern california's coast range ophiolite, are targeted for geochemical study. fracture zones in these ~150-million-year-old rocks were hotspots of microbial activity under ancient conditions in the subsurface. this work uses an array of geochemical tools to map the chemistry of materials formed in fractures and applies a high energy x-ray-based technique (fe k edge xanes) to define how oxidized or reduced bound iron in fracture fill minerals may be, as evidence for biogeochemical cycling of iron (for energy) in the past. research involves collaboration with professional beamline scientists at brookhaven national lab and with topic expert dr. d. dyar of mount holyoke college.

increased understanding of the mineral reactions in this rock type (an enormous, continuous layer beneath the global seafloor and also present in extensive blocks at earth's surface) brings multiple societal benefits: the incompletely understood emissions of naturally forming methane (a greenhouse gas) and hydrogen (a flammable but quickly lost gaseous product) from these rocks may be better constrained using geochemical models; the release of iron and associated metals (e.g., health-damaging  $\text{Cr}^{6+}$ ) into percolating water passing through these rocks may be charted and flagged for public health attention; and the case for engineered reaction of these kinds of rocks with carbon dioxide to generate sequestered carbon in solids may be evaluated. completion of this research will also ensure that multiple new generation geoscientists will be trained in cutting edge analytical tools, through **diversity**- and equity-minded graduate and undergraduate education. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: SaTC: CORE: Small: Flanker: Automatically Detecting Lateral Movement in Organizations Using Heterogeneous Data and Graph Representation Learning

Awardee: Trustees of Boston University

Amount: \$250,000.00

Abstract: in modern cyberattacks, adversaries do not target single computer systems. instead, they first set an initial foothold into a company's network and later amplify their breach by compromising additional assets, until they reach their final target inside an organization. this process of advancing computer breaches is known as lateral movement. detecting lateral movement is challenging, because attackers can use multiple vectors for infection (e.g., phishing emails) and computer systems in a network present a large degree of **diversity** (e.g., workstations, network equipment). for this reason, no comprehensive system to effectively detect lateral movement is currently available. yet, detecting and stopping computer breaches as soon as possible is critical to ensure

the safety and the prosperity of u.s. corporations and citizens. the aim of this project is to fill this gap by developing flanker, a system able to automatically detect lateral movement in the network of an organization. unlike existing approaches, the goal of flanker is to operate on a variety of data sources (e.g., data coming from network and applications) to be able to detect cyberattacks as they span different online services and computers across the organization. this project consists of four phases. in the first phase the investigators collect heterogeneous datasets from a variety of sources and develop techniques to clean them from noise and anonymize them to protect the identity of users. in the second phase this data is used to build a graph that represents network activity, and graph representation learning approaches are used to build a model for this network activity. in the third phase this model is used to automatically detect lateral movement attacks, by either applying anomaly detection or supervised learning techniques. finally, the investigators develop visualization techniques to enable a security analyst to properly understand the detection results and adopt appropriate countermeasures against the attack. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: STEPP-NET: Steppe Parasite Networks

Awardee: New Mexico Museum of Natural History Foundation

Amount: \$248,127.00

Abstract: this project focuses on collecting and describing mammals and their tapeworm and flea parasites from the grasslands of central asia. these parasites are highly diverse and ecologically important groups, and many are sensitive indicators of ecosystem quality; further, the parasitic infections they cause can have major negative impacts on wildlife. they also can play an important role in transmitting diseases from wild to domesticated species, and also to humans. however, knowledge of the **\*\*diversity\*\*** of parasite species, their geographic distributions, and the precise hosts they occur on and in remains highly fragmentary for much of the world. central asian mammals and their associated parasites are particularly highly imperiled but also little studied. this project will collect new material and study how tapeworm and flea parasites from the region evolve in conjunction with their mammalian hosts; it will also consider how the hosts and parasites have responded to various ecological changes across the region. this work is extremely time-sensitive, with many central asian ecosystems on the cusp of major land use change as economies shift and major construction occurs in the region. numerous specimens will be collected, and these will serve as a repository of parasite **\*\*diversity\*\*** useful for assessing how future global change influences the distribution of parasites and their hosts. this may ultimately improve public health outcomes. the work will also involve training the next generation of early-career stem researchers for careers in bio**\*\*diversity\*\*** science. the stepp-net project will rapidly advance discovery and description of species **\*\*diversity\*\***, host associations, and community assembly, in two mammal-associated macroparasite clades - fleas and cestodes - across the vast grasslands of central asia. this region is a prototype for exploring host-parasite dynamics and spillover in response to human activity; historically, as a conduit for ancient silk road trade routes, and, currently, from intensifying land use changes and construction. stepp-net leverages existing museum specimens, new expeditionary collections in mongolia and kazakhstan, and genomic analyses of hosts and parasites to advance knowledge of species boundaries, environmental and host niche breadth, and the exploration of novel host interfaces by focal parasite clades in response to global change pressures. a key outcome of stepp-net will be an extended specimen network for central asia, in which mammal and

parasite specimens are durably linked to derived data and immediately useful in global bio\*\*diversity\*\* studies and public health initiatives. the project also creates opportunities for stem graduate and undergraduate students to participate across the spectrum of modern bio\*\*diversity\*\* science, from international fieldwork to specimen curation and digitization, genomics, and integrative taxonomy. it will build out this community of early-career stem researchers even further by developing undergraduate and graduate educational modules that are implemented across our institutions and hosted online for broader bio\*\*diversity\*\* literacy. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Effects of Mentoring Relationship Heterogeneity on Student Outcomes among NSF Research Experiences for Undergraduates (REU) Program Participants

Awardee: University of Texas at El Paso

Amount: \$247,938.00

Abstract: understanding mentoring relationships is critical to increasing \*\*diversity\*\* in stem fields. researchers at the university of texas at el paso and the university of utah propose to study the effects of mentor relationship mismatch on student outcomes during nsf research experiences for undergraduates (reu) programs. this project aims to employ a novel approach to studying mentoring by examining multilevel mentoring and demographics of students and the mentor team. the project aims to collect data from participating students and mentors from across the country at the end of the summer research program and during the next year to gauge outcomes related to stem interest and persistence and intent to follow a stem career pathway. this project aligns with the ehr core research program's goal of addressing challenges in stem interest, learning, and participation. the project aims to address three interrelated research questions, including how mentoring relationship heterogeneity impacts short-term and mid-term student outcomes, if these effects can

be moderated by interactional dynamics between mentors and mentees, and how mentoring relationship heterogeneity impacts educational, research, and career goals immediately after the reu experience and after one year. mentoring relationship heterogeneity in context provides a conceptual framework focusing on how student mentees match with multiple mentors, including graduate students and post-doctoral researchers. the concept of programmatic heterogeneity will be used to measure the dissimilarity between students' demographic background and the demographic composition of their reu program. post-reu surveys collected from the center for the improvement of mentored experiences in research (cimer) data will be used along with a matrix analysis of semi-structure individual interview responses. short-and mid-term student outcomes consist of immediate gains in working like a scientist, comfort with science skills, science identity, sense of clarity about career path, research productivity, persistence in stem major, and intent to pursue graduate school. the project seeks to advance knowledge about mentoring relationships and aims to produce mentor and mentee workshops to positively impact undergraduate research students from underrepresented groups. the project is funded by the ehr core research program that supports fundamental research focused on stem learning and learning environments, broadening participation in stem, and stem professional workforce development. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: phyloregion, computational infrastructure for biogeographic regionalization and macroecology in the R computing environment

Awardee: Southeastern Louisiana University

Amount: \$246,317.00

Abstract: establishing geographical comparisons based on shared biota is crucial to the study of biogeography and for managing biological **\*\*diversity\*\*** in the face of rapid warming of the earth's

climate. however, the computational tools to analyze and manipulate the massive-scale species biogeography data has not been fully developed. historically, classifications of biogeographic regions were based on descriptions of the ecology, taxonomic composition or vegetation features of regions. recent approaches provided more quantitative, and objective classifications, but broadly recapitulated earlier efforts and overlooked the evolutionary implications captured by the shared phylogenetic relationships of species. because the field of biogeography has traditionally developed as an observational science rather than an experimental one, developing replicable analytical tools for biogeography into reproducible workflows is critical. the r software package `phyloregion` ? designed for biogeographic regionalization and macroecology ? can overcome these computational challenges. it contains tools for biogeographical regionalization, macroecology, conservation, and visualization, and has potential application in various disciplines including evolution, microbial **diversity**, systematics, ecology, phylogenetics, and many others. in this project, the research team plans to substantially increase computational efficiency of functions in `phyloregion`, to add new functionality, and create a model for user-guided software development in biogeography. the project will develop and implement new tools in `phyloregion` for biome evolution and biogeographical investigations. novel grade of membership model that represents sampling units as partial memberships in multiple groups will be established to analyze large biogeographic datasets. it will extend `phyloregion` with new tools to visualize patterns of biogeography, macroecology and evolution. `phyloregion` will be enhanced to pass objects between r and `revbayes` (a c++ tool for bayesian phylogeography) for phylogeographic visualization through r. finally, it will introduce new tools for conservation that reflect the key dimensions of phylogenetic **diversity** including richness, divergence and regularity. `phyloregion` is already widely used and represents one of only a few biogeographical resources in r tailored for megaphylogenies and macroecological datasets. this research will create new, open-source, and freely distributed software tools with potential for transformative impact in biogeography and beyond. workshops and conferences will be used for dissemination, and to provide introduction to intermediate r coding and implementation of

biogeographical tools. workshops will target a mix of faculty, postdocs, and especially graduate and undergraduate students, who will be trained on the use and application of phyloregion in their research, and to help develop their own novel biogeographic functions to assemble into an r package. the research team will work with existing **\*\*diversity\*\*** programs at texas a&m university-corpus christi and southeastern to recruit diverse undergraduate participants, and provide resources for them to learn about graduate school. all products from this project will be disseminated free and open-sourced through computer codes, publications, conferences, workshops and vignettes. phyloregion vignettes will be used to create an upper-division course for undergraduate and early graduate students. the grant will support the mentoring of one postdoctoral researcher and a graduate student and many undergraduates. women and traditionally underrepresented groups will be specifically encouraged to apply for the postdoctoral research position, as well as for the workshops. the phyloregion project can be accessed at <https://cran.r-project.org/package=phyloregion> this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Testing an Integrative Model of the Social-Psychological Drivers of Participation in Relational Organizing

Awardee: Colorado State University

Amount: \$245,057.00

Abstract: relational organizing is a promising approach for achieving rapid, widespread community action for environmental conservation and other pro-social outcomes. relational organizing involves enlisting motivated volunteers to share information about and encourage others they know to engage in a desired behavior. it is effective because it harnesses the power of people's social connections, which people are generally motivated to maintain, to help spread new information and

create new social norms. although a growing number of studies have documented the effectiveness of relational organizing, a key challenge to implementing this approach is scaling it up, or encouraging a larger number of individuals to reach out to others they know. studies find that most people who are committed to participating in a conservation behavior in their personal lives are reluctant to reach out to others about this behavior. preliminary research suggests this may be a result of specific social-psychological barriers that prevent people from reaching out to others, such as their fear of being judged negatively. this project examines these barriers through public surveys, and develops and experimentally tests messaging approaches for reducing these barriers to encourage greater participation in relational organizing. to do so, the researchers partner with an international ngo, local government, and private industry to focus on a context with immense environmental, health, and animal welfare impacts: relational organizing to reduce meat consumption. the team develops practical handbooks and webinars summarizing the findings to inform the efforts of numerous organizations seeking to harness the power of relational organizing for pro-social behavior.

scaling up the relational organizing approach requires understanding, synthesizing, and developing interventions to address the most salient factors driving people's willingness to reach out to others. the researchers advance a theoretical model of the social-psychological drivers of participation in relational organizing. the model proposes that participation in relational organizing is influenced by: 1) personal norms about reaching out to others; 2) activist social identity; 3) attitudes towards and past engagement in the target behavior; 4) perceptions of others' beliefs about the issue and about reaching out to others about the issue; and 5) beliefs about the efficacy of relational organizing. to test this model, the team first conducts surveys to examine the explanatory power of the model and identify the social-psychological variables that are most associated with participation in relational organizing for reducing meat consumption. the results of the surveys inform the development of messaging interventions to address the most important social-psychological factors. the team tests the effectiveness of the messaging interventions at enhancing relational organizing for reducing meat consumption first

through online experiments and then through field experiments in collaboration with an international ngo, local government, and private sector partners. in the field experiments, they track vouchers for meatless meals that respondents can give to others as indicators of effective relational organizing.

the research addresses three gaps in the literature on pro-environmental and pro-social behavior. first, most studies have focused on motivating personal-sphere behaviors, rather than more collective behaviors that involve engaging with others. the team addresses this gap through the focus on motivating individuals to reach out to others to facilitate relational organizing. second, there is a lack of understanding of the **\*\*diversity\*\*** and relative importance of social-psychological factors influencing whether people reach out to others in their social network. this gap is addressed through the development and testing of the theoretical model. finally, few studies have tested the impacts of theory-based interventions on real-world indicators of conservation behavior, particularly on collective behaviors related to bio**\*\*diversity\*\*** conservation and food choices. this project addresses this gap through a field experiment that implements a real-world relational organizing campaign. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Trace Elements in Pyrite?Validation and Calibration of a Novel Paleoenvironmental Proxy

Awardee: Central Michigan University

Amount: \$244,516.00

Abstract: life in the oceans is often limited by the availability of nutrients, such as nitrogen and phosphorus. other elements occurring in far lower abundances are also bioessential and potentially limiting?particularly trace metals such as iron and molybdenum. these metals are co-factors in many biological processes, and their distributions through time and space are strongly coupled to oxygen levels in the oceans; weathering of the continents; evolving atmospheric composition; and biological

evolution. all of these factors tie intimately to climate change as a critical driver and consequence of metal cycling on land and in the oceans. yet, despite extensive study of metals in modern and ancient oceans, basic gaps remain in our knowledge because of inadequate testing of certain chemical methods, particularly in the modern oceans. these methods, once refined, would allow for more confident exploration of a vast array of past conditions at earth's surface far beyond those seen today. from that reinforced vantage, researchers can begin to imagine more rigorously and comprehensively what may lie in our future. one of the most promising methods for "time travel" through earth's evolving oceans is elemental analysis of pyrite, an iron sulfide mineral common today and in the past that may provide easily accessible and highly preservable historical archives. surprisingly, despite the advantages that may lie with this approach and hints of success already, no previous effort has attempted to validate and calibrate the pyrite tracer in modern oceans where present environmental conditions, local and global, can be tied directly to the composition of the mineral. this study is the first comprehensive investigation of these relationships in modern systems, strengthened by targeted experiments and novel analytical techniques. the principal expected outcome is an improved understanding of the controls and consequences of change at earth's surface as expressed in evolving ocean chemistry past, present, and future and the cause-and-effect relationships with co-evolving life. many studies are now using a technique called laser ablation-inductively coupled plasma-mass spectrometry (la-icp-ms) to measure trace metal contents of pyrite as a tracer for past marine conditions, and the initial results are encouraging. that said, there is still little mechanistic understanding of how and when trace elements are incorporated into pyrite and how these patterns and controls vary across environmental gradients. these uncertainties weaken their utility. the relationships among local controls and the capture of potentially global signals remain largely unknown. thus motivated, this study is designed around a two-pronged approach: (1) sampling in five classic, well-studied modern marine environments with a well characterized **"diversity"** of primary environmental conditions and (2) complementary, carefully conceived laboratory simulations designed to provide unprecedented insight into the mechanisms of

trace metal uptake by iron sulfide minerals and their sensitivity to environmental backdrops. the ultimate goal is to expose the strengths and weaknesses of the proxy and best practices while revealing new opportunities, such as the possibility of tracking the availability of bioessential trace metals in the ancient deep biosphere. plans include analyzing pore waters and sediments from diverse settings in modern oceans and interpreting those data within the framework of experimental results to reveal how trace metal content scales with conditions in the surrounding environment. the utility of the approach will be explored further using novel, highly sophisticated analytical methods applied at high resolution to characterize experimental and natural samples. this will be the first systematic study that correlates pyrite metal contents with metal availability in surrounding fluids and relates such data more generally to the wide range of environmental parameters and proxies often included in studies of earth's ancient biosphere. the impacts of this study will extend broadly through outreach opportunities targeting middle and high school students and ucr undergraduates placed in the lyons lab, while championing **\*\*diversity\*\*** and inclusion at all levels. that community footprint will be expanded through a recurring public lecture series and an on-campus science festival presented entirely in spanish, among other already tested community-directed efforts. at cmu, plans include a geochemical study at two middle schools in flint (mi) emphasizing water quality and use of those data to construct a new, much-needed community-driven water quality database for flint. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: SHF: Small: Feedback-Driven Mutation Testing for Any Language

Awardee: Northern Arizona University

Amount: \$244,487.00

Abstract: testing, validation, and verification are all central activities in programming and software engineering. unfortunately, existing techniques for testing remain inadequate for finding and

eliminating key vulnerabilities before software deployment -- even the most critical modern software is rife with security vulnerabilities and defects that ultimately cost the economy billions of dollars annually in lost productivity and compromised data. a technique known as "mutation testing" has been researched since the 1970s; it aims to help software engineers improve their tests and their software at the same time, by automatically adding bugs to a program and checking whether the test suite can detect them. although in theory this technique is extremely effective for improving software quality, there are several fundamental factors that prevent it from being widely used in practice: it is difficult and time-consuming to use, and the tools that exist for it cannot all handle the **\*\*diversity\*\*** of program languages that are deployed in modern software systems. this project will tackle these challenges and allow this important technique to be used to improve quality of real-world software by developing efficient tools that can apply mutation testing to programs written in any language; prioritize the output of the tools to reduce the amount of time and effort needed to make maximal use of them; and incorporate user feedback into the technique to maximize testing efficiency. the project will be evaluated on real-world open source software like the linux kernel, and build on the researchers' previous collaborations to substantially improve program and test effort quality on critical real-world software. the core problem this project aims to address is making program mutants practical in nonresearch settings, in a way that meets the needs of developers and test engineers, by making it possible for someone creating or enhancing a test suite, or developing code and test suite in tandem, to (1) use "just enough" mutation testing for their needs, maximizing benefit gained in exchange for work performed, and (2) to work in any programming language without worrying about the quality of tool support provided for mutation testing, and without sacrificing the ease of understanding of source-based mutants, while easily adding custom mutation operators that target their specific software development task. this project aims to adapt the furthest-point-first metric previously used in fuzzer bug triaging to the problem of maximizing the novelty of mutants examined by a user, in order to make it possible to quickly discover unkilld mutants that expose serious defects in a testing or verification effort. however, novelty alone is not

sufficient: feedback-driven mutation testing must also help users avoid inconsequential, equivalent mutants, kill mutants high in the dominance hierarchy, and (most importantly) incorporate user feedback. if a user marks a mutant as inconsequential, or equivalent, or (especially) high impact, then that information must be used to inform the ranking of future mutants as well. in order to make such an approach maximally valuable, this project also proposes to improve the state-of-the-art in source-level multilingual mutant generation, allowing users to easily generate mutants for new programming languages, or even for custom dsls that are part of a specific project. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: SBIR Phase I: Ultra Wide Band (UWB) Ka-Band Flat Panel Antenna

Awardee: ALLBEAMS, INC.

Amount: \$242,000.00

Abstract: the broader impact/commercial potential of this small business innovation research (sbir) phase i project seeks to advance the development of ultra-wide band (uwb) flat panel antenna (fpa) which is a catalyst for ubiquitous, satellite-based communication. this project focuses on the international telecommunication union (itu) ka-band frequencies (tx 27.5-31ghz, rx 17.7-21.2ghz) with fpa capable of connecting to all three constellations: low earth orbit (leo), medium earth orbit (meo), and geostationary orbit (geo) simultaneously. the development of these fpa will enable a new era of satellite communication, making the internet network a global network regardless of the

user's location on earth, with speeds comparable to, and in some cases higher than, land-based networks. fpa technology may spur further research into higher millimeter-wave (mmwave) frequencies and the bandwidth benefits they offer. fpa technology may also be an enabler of the future hybrid wireless network used in connected cars and machines with direct line of sight (los) to a satellite. this small business innovation research (sbir) phase i project aims to develop a novel method of radiating aperture design for high bandwidth, high efficiency, low-cost, and lightweight next-generation satellite terminal flat panel antenna (fpa). recent activities in the satellite industry such as the new leo constellations and high-throughput satellite (hts) networks in geo orbit have prompted the development of the fpa to be used in the user's terminal. to support such a multi-orbit constellation, certain performance criteria such as bandwidth, polarization **\*\*diversity\*\***, cross-polarization rejection, and antenna gain need to be met with sufficient margin to guarantee reliable communication links. the existing flat panel antenna technologies are either narrowband or bulky, which makes them not suitable for emerging satellite technology or multi-orbit communication. as a result, there is a need for a new flat panel antenna that can cover the entire ka-band frequencies (both tx and rx) to unlock the full potential of satellite communication in the ka-band. the core of this project is developing the novel technology with all the attributes needed for multi-orbit communication. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Awardee: ALLBEAMS, INC.

Amount: \$242,000.00

Abstract: the broader impact/commercial potential of this small business innovation research (sbir) phase i project seeks to advance the development of ultra-wide band (uwb) flat panel antenna (fpa)

which is a catalyst for ubiquitous, satellite-based communication. this project focuses on the international telecommunication union (itu) ka-band frequencies (tx 27.5-31ghz, rx 17.7-21.2ghz) with fpa capable of connecting to all three constellations: low earth orbit (leo), medium earth orbit (meo), and geostationary orbit (geo) simultaneously. the development of these fpa will enable a new era of satellite communication, making the internet network a global network regardless of the user's location on earth, with speeds comparable to, and in some cases higher than, land-based networks. fpa technology may spur further research into higher millimeter-wave (mmwave) frequencies and the bandwidth benefits they offer. fpa technology may also be an enabler of the future hybrid wireless network used in connected cars and machines with direct line of sight (los) to a satellite. this small business innovation research (sbir) phase i project aims to develop a novel method of radiating aperture design for high bandwidth, high efficiency, low-cost, and lightweight next-generation satellite terminal flat panel antenna (fpa). recent activities in the satellite industry such as the new leo constellations and high-throughput satellite (hts) networks in geo orbit have prompted the development of the fpa to be used in the user's terminal. to support such a multi-orbit constellation, certain performance criteria such as bandwidth, polarization **\*\*diversity\*\***, cross-polarization rejection, and antenna gain need to be met with sufficient margin to guarantee reliable communication links. the existing flat panel antenna technologies are either narrowband or bulky, which makes them not suitable for emerging satellite technology or multi-orbit communication. as a result, there is a need for a new flat panel antenna that can cover the entire ka-band frequencies (both tx and rx) to unlock the full potential of satellite communication in the ka-band. the core of this project is developing the novel technology with all the attributes needed for multi-orbit communication. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: SBIR Phase I: A robotic system for removal of invasive plant species

Awardee: BIRDHABITATBOT LLC

Amount: \$240,060.00

Abstract: the broader impact of this sbir phase i project is to improve habitat for native plants and wildlife by removing invasive plants with a mobile robot. worldwide invasion by non-native plant species is a primary concern in forest ecosystem health and bio\*\*diversity\*\*. within the highly fragmented landscape of the connecticut forest, two invasive plants significantly contribute to the degradation of habitat: japanese barberry and multiflora rose. current methods to eradicate them are time-consuming, expensive, and ultimately ineffective. this project presents a novel method of detecting and removing japanese barberry and multiflora rose. deep learning technology enables additional use with other invasive species, increasing the system's value throughout natural resource management. additionally, once programmed, the robots will be easily operated, making them usable for a variety of personnel. this sbir phase i project will advance current robot prototypes being tested for weed detection and removal. there is currently no mobile robot designed and programmed to remove understory invasive shrub species in a deciduous forest ecosystem. the technical challenges that will be addressed in building a feasible robot prototype include navigating over the unstructured terrain of the forest floor, developing a cutting attachment for the robotic arm, and creating a hybrid soft-rigid platform to withstand forest floor hazards while averting tree seedling damage. the proposed system will operate as follows: (1) an unpiloted aerial system (uas, i.e., drone) flies over the canopy to capture images of the forest understory; (2) images are then labeled and converted to species location maps; and (3) utilizing these maps, a semi-autonomous mobile robot navigates to the invasive species locations for removal. the robots will be programmed for semi-automated missions monitored by an operator nearby at a safe distance to ensure worker safety. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: HSI ATE Hub 2: Professional Development for Culturally Responsive Technician Education

Awardee: Westchester Community College

Amount: \$238,123.00

Abstract: this project aims to better serve and support a diverse population of students who are pursuing credentials in skilled technical fields. to do so, the project will guide faculty to adapt and implement culturally responsive instruction in technician education courses. the project is designed to increase the retention of hispanic students in stem career pathways, particularly in advanced-technology fields. the project builds on the hispanic serving community college kickstarter project, the hispanic serving institutions hsi/ate hub project, and the westchester community college photonics and laser project. the project team will develop, pilot test, and disseminate a faculty professional development model that can help to shift faculty understanding, practice, and mindset from emphasis on perceived student deficits to asset-based thinking and mutual respect. the professional development will be organized into three tiers. tier 1 is designed to establish awareness and support first steps. tier 2 will focus on the development, implementation, and testing of culturally responsive instruction practices in technician education. tier 3 will focus on creating a community of instructors and emerging leaders that engages in practice, theory building, and applied research into effective educational practices. the overall project goal is to develop faculty knowledge, skills, values, attitudes, and mindset so that more hispanic students will complete advanced technology programs. in doing so, the project can increase the **\*\*diversity\*\*** of the technician workforce and help to mitigate disproportionate impacts of covid-19 on hispanic communities. this collaboration includes faculty and administrators in technician education programs, higher education researchers, experts in culturally responsive instruction, and industry partners to further conceptualize, operationalize, and test the validity of culturally responsive instruction in the skilled technical fields of applied engineering and applied computing and

cyber-security. additionally, the project will test the hypothesis that micro-credentials are valuable for incentivizing faculty participation in project activities and that micro-credentials will be recognized by educational and industry stakeholders as valuable evidence of expertise and experience. the mixed method evaluation is process -oriented to facilitate development of a model and outcomes-oriented to assess faculty and student outcomes that includes assessment of changes in knowledge/awareness, skills/behavior, and attitudes/mindset. this project is funded by the advanced technological education program that focuses on the education of technicians for the advanced-technology fields that drive the nation's economy. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: How are Flood Basalts Fed? A Textural Investigation of the Chief Joseph Dike Swarm

Awardee: University of West Georgia

Amount: \$238,043.00

Abstract: this award is funded in whole or in part under the american rescue plan act of 2021 (public law 117-2). flood basalts are the earth's most extensive expressions of volcanism. the eruption and emplacement of these voluminous magmas have been linked to global climate shifts and many extinction events. the columbia river flood basalts in oregon, washington, idaho, and nevada are the most recent and best-preserved example of this voluminous volcanic activity. it is believed that degassing during their eruption 17-14 million years ago influenced global temperatures. a key aspect to understanding magmatic systems is deciphering how the magma is transported from depth to surface. at the chief joseph dike swarm in oregon, a portion of the magmatic plumbing system of the columbia river flood basalts is preserved and exposed. while the transport mechanism for these magmas is well understood (i.e., sheet magmatism), the style and timing of magmatism is poorly constrained. namely, were the chief joseph dikes produced through single-pulse events or grown through time as a series of magmatic pulses where each of them contributed with tectonic deformation and degassing? detailing the mechanism of transport and emplacement could constrain the rates of surface deformation and volatile release during magmatism. this study will utilize relatively fast, simple, and resource-light methodologies that will inform us of the dike emplacement and growth mechanisms by studying in great detail the crystal textures recorded in the dikes themselves. this team's research project was designed from the ground up as an unparalleled research experience for underrepresented minority (urm) undergraduate students who will be recruited to participate in the research and dissemination process. this research is built intentionally to contribute to making the geosciences a diverse, equitable, and inclusive discipline by promoting the development of future leaders and mentors for subsequent students in stem research and education. the program will benefit the urm student cohorts with the knowledge, motivation, and inspiration to pursue focused science careers to solve us-national and global challenges. this project will investigate the tectonomagmatic evolution of the columbia river flood basalts (crfb), as recorded within the chief joseph dike swarm (cjds). the team will develop and disseminate a

technique that uses electron backscatter diffraction (ebbsd) to identify dike emplacement style using textural analyses. analyses of dike centers will be performed on a statistically significant number of dikes to meaningfully constrain the actual proportion of single-event and pulsed emplacement styles. dike-center textural analyses will be calibrated using field observations and a subset of detailed textural profiles collected across dikes to identify the overall cooling history. the information generated by the proposed work will address long-standing questions surrounding the generation of space to accommodate hundreds to thousands of dikes with considerable average thicknesses. this will impact future research by generating a detailed database of dike textures and morphologies that will allow future comparisons with other crfb dike swarm systems and cross-comparison with other dike swarms worldwide. results will provide insights into magma transport efficiency through the crust and the relationship between tectonics and magmatism. characterizing the textures of pulsed assembly of dikes or dikes that experienced sustained high reynolds number flow will add to our overall understanding of magmatic plumbing systems and their connection to mineralization zones and hydrothermal fields. furthermore, the project will create linkages with education organizations in the state of georgia. researchers will train and professionally develop six underrepresented minority (urm) student research scientists over three years. the project will broaden the participation of urms in geosciences as we will fully leverage the existing student populations from historically black colleges and universities and minority-serving institutions in georgia. the program will benefit the urm student cohorts with the knowledge, motivation, and inspiration to pursue focused science careers to solve us-national and global challenges. more importantly, this research is built intentionally to make geosciences a diverse, equitable, and inclusive discipline. their mentoring experience is built around creating a welcoming environment with comprehensive guidance by relatable mentors and academic socialization, which have proven to be integrative tools for urms. they want to foment the extraordinary untapped talent that urm students bring to geosciences. to do this, researchers need to work towards transformative change in the way they plan their research. this team believes that their program design strives to bring justice, **\*\*diversity\*\***, and inclusion to the

field of geoscience. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Digitization TCN: Extending Anthophila research through image and trait digitization (Big-Bee)

Awardee: University of California-Berkeley

Amount: \$235,963.00

Abstract: declining populations of bees impact plant-pollinator interactions in both natural and agricultural systems. while bees and other insects pollinate most wild plants, and are critical to sustain a large proportion of global food production, they are decreasing in both numbers and **\*\*diversity\*\***. our understanding of the factors driving these declines is limited because we lack sufficient data on the distribution of bee species, and on the behavioral and anatomical traits that may make them either vulnerable or resilient to human-induced environmental changes, such as habitat loss and climate change. fortunately, wild bees have been collected by researchers and deposited in natural history collections for over 100 years, retaining a wealth of associated attributes that can be extracted from specimen images. this project will digitally capture data and images from these historic specimens, develop tools to measure bee traits from these images, and generate a comprehensive bee trait and image dataset to measure changes through time. this will increase our understanding of specific traits that put bee species at risk of decline - a critical need for both sustaining our agricultural economy and the conservation of our natural resources. in addition, the large image datasets created by this project can be used for new artificial intelligence identification tools that will help improve our future pollinator observation and monitoring efforts. the big-bee thematic collection network (big-bee tcn) will create over one million high-resolution 2d and 3d images of bee specimens, representing over 5,000 worldwide bee species, including all of the major

pollinating species of the united states. the big-bee network includes 13 institutions and partnerships with us government agencies. novel mechanisms for sharing image datasets will be developed and datasets of bee traits will be available through an open data portal, the bee library, for research and education. the big-bee project will engage the general public in research through community science via crowdsourcing trait measurements and data transcription from images. in addition, training and professional development for natural history collection staff, researchers, and university students in data science will be provided through the creation and implementation of workshops focusing on bee traits and species identification. all data resulting from this award will be shared with and publicly available through the national digitized biocollections resource, [idigbio.org](http://idigbio.org). this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Research Synthesis of Effective Inclusion Practices for Neurodiverse K-12 Learners in Informal STEM Learning Contexts

Awardee: Northern Arizona University

Amount: \$234,796.00

Abstract: informal stem learning environments, programs, and policies can be designed to support and promote neuro\*\*diversity\*\* through inclusive practices. this project will explore the benefits of informal stem learning for k-12 neurodiverse learners through a systematic review and meta-analysis of extant literature and research grounded in the theory of social model of ability. this framework is an asset-based approach and aims to promote social, cognitive, and physical inclusion, leading to positive outcomes. using various quantitative and qualitative methodologies, this project endeavors to collect and synthesize the evidence for supporting and enhancing accessibility and inclusiveness in informal stem learning for k-12 neurodiverse learners. it will explore key features of informal stem learning and effective, evidence-based strategies to effectively

engage children and youth with neurological conditions such as autism spectrum disorder, attention deficit hyperactivity disorder (adhd), dyslexia, and dyspraxia, in informal stem learning environments. the findings of this complex synthesis will provide a timely contribution to deeper understanding of supports for neuro\*\*diversity\*\* while also highlighting areas that inform further research, shifts in practice, and policy. the systematic review will occur over a two-year period. it will focus on identifying program elements that promote inclusion of children and youth with neurodevelopmental disabilities in informal stem learning contexts. specifically, the review will explore two overarching research questions and several sub-research questions: rq1. what program elements (teaching and learning variables) in informal stem learning settings facilitate inclusion of k-12 neurodiverse stem learners? sub-rq1a: what are the overlapping and discrete characteristics of the program elements that facilitate social, cognitive, and physical inclusion? sub-rq1b: in what ways do the program elements that facilitate inclusion vary by informal stem learning setting? rq2: what program elements (teaching and learning variables) in informal stem learning settings are correlated with benefits for k-12 neurodiverse stem learners? sub-rq2a: what are the overlapping and discrete characteristics of the program elements that correlate with increased stem identity, self- efficacy, interest in stem, or stem learning? sub-rq2b: in what ways do the program elements that correlate with positive results for students vary by informal stem learning setting? the research synthesis will consider several different types of studies, including research and evaluation; experimental and quasi-experimental designs; quantitative, qualitative, and mixed methods; and implementation studies. the research team will (a) review all analyses and organize findings to illustrate patterns, factors, and relationships, (b) identify key distinctions and nuances derived from the contexts represented in the literature, and (c) revisit and confirm the strength of evidence for making overall assertions of what works, why, and with whom. the findings will be disseminated in practice briefs, journal articles, the aisl resource center, as well as presentations and materials for researchers, practitioners, and informal stem leaders. ultimately, this work will result in a comprehensive synthesis of effective informal stem learning practices for neurodiverse k-12 learners and identify

opportunities for further research and development. this literature review and meta-analysis project is funded by the advancing informal stem learning (aisl) program, which seeks to advance new approaches to, and evidence-based understanding of, the design and development of stem learning in informal environments. this includes providing multiple pathways for broadening access to and engagement in stem learning experiences, advancing innovative research on and assessment of stem learning in informal environments, and developing understandings of deeper learning by participants. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Eigenvalue Comparison and Integral Curvature

Awardee: University of California-Santa Barbara

Amount: \$234,436.00

Abstract: various problems of mathematical physics can be modeled by the laplacian or more generally schrodinger equations. the difference between the first two eigenvalues of the laplacian is referred to as the fundamental gap, which represents the energy needed to excite a particle from ground level to the next level in quantum mechanics. in the first project, the principal investigator will estimate the fundamental gap for various spaces. the second project relates to volume entropy which is a fundamental geometric invariant for compact smooth manifolds. this concept is closely related to other notions of entropy found in dynamical systems and plays an essential role in differential geometry and geometric group theory among others. the work on entropy rigidity is related to optimal transport, information geometry and discrete geometry. the project will also support educational activities and **\*\*diversity\*\*** through mentoring graduate students and postdocs; recruiting women and other underrepresented groups; organizing seminars, workshops and research programs promoting young scholars. the material discussed in the proposal will be the subject of an advanced graduate course at ucsb in fall 2021. the project has three parts. the first is about eigenvalue and fundamental gap estimates of the laplacian with dirichlet boundary conditions on a convex domain in locally symmetric spaces by comparing with some suitable 1-dim model. the second concerns volume entropy comparison and rigidity for metric measure spaces with

curvature lower bounds. the last is to study integral curvature pinching for the critical power using ricci flow. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: 3 Myr of Laurentide Ice Sheet History Inferred from Cosmogenic Nuclides in Ice-Rafted Debris

Awardee: Boston College

Amount: \$232,428.00

Abstract: the laurentide ice sheet over north america caused large changes in climate and sea level as it grew and shrank over ice age cycles during the past three million years, but little is known about the ice sheet's detailed history throughout this interval. this project will determine how big the ice sheet was through time using chemical markers in layers of sand on the seafloor that melted out of icebergs drifting from north america. this method provides a new way to learn about past changes in the laurentide ice sheet and test ideas for how climate change and ice sheets affect each other. the results should help with predictions of sea-level rise far into the future due to global warming and melting polar ice sheets. this project will also educate and involve a wide range of people in climate science in several ways. videos about the research will be sent to boston public schools through the bostem organization to help students in the area learn about careers in science. the researchers will participate in activities through the mcauliffe center for integrated science learning at framingham state university to teach middle and high school students and teachers about climate change. college students will help with the research during summers through the integrated science for society nsf research experience for undergraduates at boston college, which tries to find students from underrepresented minority groups or who are the first in their family to go to college and that do not have research possibilities at their school. lastly, the project will support a female ph.d. student already at boston college and an m.s. student at the university of vermont. the laurentide ice

sheet over north america was one of the largest drivers of climate and sea level over the ice age cycles of the past three million years, but its history over this interval is shrouded in uncertainty largely due to limitations of conventional geologic records. this project will take a new approach, measuring the concentrations of rare chemicals in quartz sand layers from ocean sediment cores that melted out of drifting north american icebergs. the chemistry of the sand reflects the history of north american ice sheet cover because the chemicals accumulate in land surfaces exposed to the atmosphere but radioactively decay away when the surfaces are buried by ice. four sediment cores will be analyzed to reconstruct long-term laurentide ice sheet evolution, and analyses of sand samples collected across eastern canada will show how their chemistry records ice sheet variations over the most recent ice age cycle. together with similar reconstructions produced over the past five years from greenland and antarctica, these records will provide a comprehensive picture of how these three ice sheets varied in the past and contributed to global sea level. the results will offer much-needed constraints to test theories and models of paleo-ice sheet change, useful for improving long-term future projections of ice sheets on earth today. this project will increase literacy and **diversity** in climate science in multiple ways. ?science bites? videos about the research will be distributed to boston public schools through bostem to demystify careers in science. participation in ongoing efforts through the mcauliffe center for integrated science learning at framingham state university will help educate middle and high school teachers and students on climate change. this project will support an existing female ph.d. student at boston college and an m.s. student at the university of vermont. summer undergraduate research assistants will be recruited through the integrated science for society nsf reu at boston college, which seeks to attract underrepresented minority and first-generation college students from schools with limited research opportunities. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Statistical Learning and Inference for Single-Cell RNA Sequencing

Awardee: University of Chicago

Amount: \$230,000.00

Abstract: single-cell genomics is an emerging technique that has become an indispensable tool for understanding cellular **\*\*diversity\*\*** and cell activities. among the various single-cell sequencing

technologies, single-cell rna sequencing (scrna-seq), simultaneously measuring tens of thousands of rnas inside each individual cell, is the most mature and widely used technology. this project aims to develop new analytical tools for scrna-seq with explicit and coherent statistical frameworks to provide reliable uncertainty quantification and inference. at the same time, the new tool will retain the scalability and user-friendly features in existing algorithmic-based methods. the pi will focus on building probabilistic models for machine learning frameworks such as deep learning and address new challenges to account for biological randomness and technical noise in scrna-seq. the pi will develop open-source software for analyzing scrna-seq data to help scientists understand cell development, the mechanism of gene regulation, and cell-type-specific features of common diseases. because of the interdisciplinary feature of this project, it will also train both graduate and undergraduate students within and outside statistics to become future scientists in the fast-evolving area of applied statistics and computational biology. the pi plans to focus on three research problems that are unique to the analysis of single-cell data: trajectory inference, cell type deconvolution, and gene-gene co-expression / co-bursting. for trajectory inference, the pi will incorporate a hierarchical mixture model into a deep neural network to infer trajectories shared by cells from multiple sources. in the cell type deconvolution problem where scrna-seq data are used as references to estimate cell type proportions in bulk samples, the pi will derive asymptotically valid confidence intervals of the estimated cell type proportions without parametric assumptions and account for three major uncertainty-inflation factors: the technical noise, biological heterogeneity across individuals, and dependence across genes. finally, in the gene-gene co-expression / co-bursting analysis, the pi will estimate the true gene-gene correlation and co-bursting pattern from noisy observed data and design a scalable multiple testing framework that can efficiently find gene pairs that are co-expressed or co-bursting. the pi also aims to link the co-expression and co-bursting signals with the enhancer-promoter contacts in the three-dimensional genome structure to understand causal mechanisms of transcriptional regulation. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's

intellectual merit and broader impacts review criteria.

Title: Collaborative Research: CPS: Medium: RUI: Cooperative AI Inference in Vehicular Edge Networks for Advanced Driver-Assistance Systems

Awardee: Kettering University

Amount: \$229,720.00

Abstract: artificial intelligence (ai) has shown superior performance in enhancing driving safety in advanced driver-assistance systems (adas). state-of-the-art deep neural networks (dnns) achieve high accuracy at the expense of increased model complexity, which raises the computation burden of onboard processing units of vehicles for adas inference tasks. the primary goal of this project is to develop innovative collaborative ai inference strategies with the emerging edge computing paradigm. the strategies can adaptively adjust cooperative inference techniques for best utilizing available computation and communication resources and ultimately enable high-accuracy and real-time inference. the project will inspire greater collaborations between experts in wireless communication, edge computing, computer vision, autonomous driving testbed development, and automotive manufacturing, and facilitate ai applications in a variety of iot systems. the educational testbed developed from this project can be integrated into courses to provide hands-on experiences. this project will benefit undergraduate, master, and ph.d. programs and increase under-represented groups' engagement by leveraging the existing \*\*diversity\*\*-related outreach efforts. a multi-disciplinary team with complementary expertise from rowan university, temple university, stony brook university, and kettering university is assembled to pursue a coordinated study of collaborative ai inference. the project explores integrative research to enable deep learning technologies in resource-constrained adas for high-accuracy and real-time inference. theory-wise, the project plans to take advantage of the observation that dnns can be decomposed into a set of fine-grained components to allow distributed ai inference on both the vehicle and edge server sides for inference

acceleration. application-wise, the pi3 plan to design novel dnn models which are optimized for the cooperative ai inference paradigm. testbed-wise, a vehicle edge computing platform with v2x communication and edge computing capability will be developed at kettering university gm mobility research center. the cooperative ai inference system will be implemented, and the research findings will be validated on realistic vehicular edge computing environments thoroughly. the data, software, and educational testbeds developed from this project will be widely disseminated. domain experts in autonomous driving testbed development, intelligent transportation systems, and automotive manufacturing will be engaged in project-related issues to ensure relevant challenges in this project are impactful for real-world applications. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Testing the reduction of aerobic habitat as a common kill mechanism for major mass extinction events

Awardee: Princeton University

Amount: \$228,080.00

Abstract: the project will study the response of marine animal ecosystems to environmental change using three mass extinction events from the geological record as study systems. specifically, the project will test the hypothesis that a large proportion of extinction during these events can be explained by the stresses that elevated temperatures and reduced oxygen availability place on animal respiration. geochemical data will be used to constrain computer simulations of changing ocean conditions during these mass extinction events. results from laboratory studies on animal respiration will then be paired with fossil data to assess whether differences in extinction intensity in space and across taxonomic groups can be explained by spatial variation in environmental change or differences among taxonomic groups in their ability to withstand environmental change. the

project will provide interdisciplinary training to a group of graduate students and post-docs. it will further impact stem education through the creation of a website that will allow access to model results so that students can visualize and explore model output to understand cause-effect relationships between continental configuration, ocean conditions, and biological **\*\*diversity\*\***. the investigators will also offer short-courses on earth system modeling and data interpretation at major conferences that will be recorded for asynchronous use. the project will also involve the development of a podcast series addressing how we reconstruct the ancient earth system and use these reconstructions to better understand the present and predict the future. in this project, the hypothesis will be tested that the loss of habitat through constraints on aerobic respiration under climate change and ocean deoxygenation can explain the magnitude, taxonomic selectivity, and latitude variation in intensity for the late devonian (frasnian-fammenian), end-permian, and end-triassic mass extinction events. paleoredox and paleoclimate proxy data and geochemical indicators of diagenetic alteration will be used for both global average and local conditions before and after each major event combined with predictions from earth system models and occurrence data from the fossil record of marine animals to separate aspects of extinction than can be explained by physiological stress from those that require other explanations. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: MCA: Partnering Land and communities for equitable and inclusive STEM learning

Awardee: Regents of the University of Idaho

Amount: \$227,519.00

Abstract: the goal of the project is to explore land education pedagogy and its curriculum and pedagogical innovations in the preparation of native and non-native educators to engage native and non-native students in environmental stem education on indigenous lands. the investigator will implement a professional development plan focused on pedagogical innovations within various teacher education and environmental stem learning programs to (a) understand the tools and technologies that can support these innovations and (b) develop new research methods for understanding the impact of these innovations on individuals, communities, and socio-ecological systems. the research builds on the investigator's prior inquiries on culturally connected identity and how technology can be used to deepen observation skills and communicate to broader audiences while not distracting from students' engagement. the project will advance this knowledge and build new collaboration through network engagement. the research project uses the actor network theory and critical indigenous research methodologies to frame the research design and approach. there are four driving questions: (1) what affordances does land education pedagogy offer in creating inclusive and epistemologically diverse stem learning environments, building more equitable relationships to particular places and to socio-ecological systems, and impacting the **\*\*diversity\*\*** of the stem workforce? (2) what tools and technologies can assist in sustaining long-term, mutually beneficial relationships to support the preparation of native and non-native educators who will engage in educational strategies that lead to diverse stem workforce on indigenous lands? (3) what are the impacts of a land education pedagogy on individual students' sense of belonging and stem identity, communities of educators' approaches to stem engagement, and the health of broader socio-ecological systems? data will be collected from k-12 and graduate students using autoethnographies, photovoice and symbol-based reflections, observations, and

network mapping. evidence will be analyzed using content and discourse analysis. the research findings will inform programs that employ land education pedagogy to shape more equitable and inclusive environmental stem education for students and teachers and to increase stem persistence among underrepresented populations. the project is funded by the mid-career advancement program that enables scientists and engineers to substantively advance their research program and career trajectory. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Land, Forest and Water Management in a Tropical Environment

Awardee: University of Cincinnati Main Campus

Amount: \$226,489.00

Abstract: this project will investigate the land and water management strategies that supported the development of complex society in a tropical environment. a primary theoretical question to be addressed in this study focuses on how the ancient inhabitants in the environmentally problematic region were able to sustain an urban population. a corollary to this question asks how agricultural intensification was achieved and how other essential resources, such as water and forest products, were managed. the research plan includes ecological assessments such as biomass and species **\*\*diversity\*\***, as well as examination of the sustainability of various land use practices all of which will be useful for the management of the region which currently co-exists in an uneasy tension in competition for land and water. the project is tri-national, involving researchers and students from multiple countries and provides training for graduate students from each country. the archaeological site provides an ideal test case for examining the changing trajectories of human-environment interactions because it grew into one of the paramount cities and political-economic powers during the new world classic period. the research will examine the hydraulic, agricultural,

and forest management strategies that allowed the persistent occupation and growth in the face of changing environmental and political economic conditions. it will provide insights into the variability of adaptive strategies and the rise of social complexity. these issues will be addressed by an interdisciplinary research team that includes professionals and students with training in botany, paleoecology, geoarchaeology, remote sensing, gis, and anthropological archaeology and will employ a unique combination of paleoenvironmental and archaeological methods. the acquisition of lidar imagery of the area will allow the team to select a variety of topographic settings, probable ancient agricultural fields, reservoirs, and residential areas for excavation and coring, thus providing data on resource management across the spectrum of environmental contexts and social strata. these analyses will include edna which offers novel insights into ancient land use and subsistence. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: RUI-CHE: Development of Organometallic Complexes for the Next-Generation of Non-Aqueous Redox Flow Batteries

Awardee: Occidental College

Amount: \$225,002.00

Abstract: with the support of the chemical synthesis program in the division of chemistry, emmanuelle despagnet-ayoub of occidental college is studying new redox active materials for energy storage. renewable power sources derived from solar energy are promising and environmentally friendly solutions for generating electric power. however, their intermittent behavior does not align with the typical energy demand. consequently, more efficient energy storage devices need to be developed. redox flow batteries are a promising energy storage technology. however, prior redox-flow technologies have considerable challenges meeting the performance requirements for grid storage applications due to their low energy density. this project, carried out primarily by

talented undergraduates, aims to find solutions to overcome these limitations. the research will be carried out synergistically with other projects promoting **\*\*diversity\*\*** in stem fields at occidental college, such as the cosmos (creating opportunities in science and mathematics for occidental students, s-stem grant) and the reap (research early access program, sherman fairchild grant) programs. emmanuelle despagnet-ayoub of occidental college is developing new redox active materials for high energy density redox flow batteries. indeed, the practical energy density of current redox flow batteries is typically low (10s of wh/l) due to the use of aqueous solutions with narrow potential windows and redox couples with limited solubility. development of organometallic complexes with a high solubility in organic solvents and tunable formal potentials will help advance the field. the pi has recently reported a strategy to anodically shift the formal potential of metal redox couples by outer-sphere coordination of lewis acids. this concept will be further probed with a variety of complex frameworks and lewis acids, in order to develop a relationship map between ligand framework-lewis acid and their electrochemical properties. the project will ultimately lead to more exciting systems involving multiple electron processes at the molecular and macromolecular levels, and the development of symmetric flow batteries with non-innocent ligands and semi-solid flow batteries with immobilized redox active species. this research project will provide research and training opportunities to undergraduates in the fields of organometallic synthesis and electrochemistry within the larger context of flow batteries and energy storage. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: EAGER: Collaborative Research: Development of an Energy-Harvesting Real-time Under-ice Monitoring System in the Arctic Ocean

Awardee: Virginia Polytechnic Institute and State University

Amount: \$225,000.00

Abstract: the arctic is home to some four million people comprising a diverse range of cultures and an economy worth about \$230 billion annually. with global concerns spanning climate change, energy resources, freshwater supplies, and sustainable economic growth, the arctic has sparked intense research and public interest. international efforts to establish sustained arctic observing systems, especially for long-term arctic ocean monitoring with near-real-time data transfer, are urgently needed. the harsh and remote conditions constraining year-round observation sites present significant logistical challenges and energy needs for sustained arctic observations. in addition, monitoring of the arctic ocean using bottom-anchored stationary platforms is limited by a lack of real-time communication between the sensors deployed and arctic operators. the ultimate goal of this project is to develop new energy harvesting and communication solutions so that it is feasible to have a real-time under-ice monitoring system in the arctic ocean. this eager project tests the capacity to address three key challenges, including sustainable power supply through energy harvesting, near-real-time data communication under the sea ice, and survivability under harsh environmental conditions. specifically, the project aims to develop novel techniques to harvest ultra-low-speed oceanic current energy using a two-level diffuser augmented turbine and a novel transverse flux generator. the harvested energy will be used to support sensors and power a novel real-time communication system through the sea ice. the proposed communication system adopts a novel antenna design that overcomes seawater attenuation effects on radio waves and creatively leverages satellite protocols to ensure the under-ice communication unit can transmit observational data to satellites. the project also explores techniques to enhance the survivability of the under-ice monitoring system, such as robust material choice and ice ridge/keel detection and avoidance systems and extends science and engineering education among k-12 and phd-level students in arctic research with an emphasis on **\*\*diversity\*\*** including female and underrepresented students. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: A Data-Driven Employer-Academia Partnership for Continual Computing Curricular Change

Awardee: Tuskegee University

Amount: \$225,000.00

Abstract: this project aims to serve the national interest by improving the supply of well-prepared computer science professionals capable of addressing the needs of american employers in the public and private sectors. this project intends to build a national partnership between employers and academia to help identify and mitigate gaps between the competencies of computing graduates and the expectations of potential employers. the project will survey computer science educators and practitioners to develop a model that defines the competencies expected by potential employers. the project team then plans to test the model at three institutions of higher education in alabama ? the university of alabama, tuscaloosa, tuskegee university, and shelton state community college. finally, the project team intends to develop tools and methods for institutions to identify and implement competency-based educational approaches for computer science across the nation. the project plans to use three interconnected strands of evidence-based activities to institute transformational change in the involved communities. first, a national strand will engage u.s. faculty in developing competency-based curricula informed by industry practitioner feedback. second, a local pilot strand intends to create transformative curricular change based on student competencies using an evidence-based change model in the three alabama institutions. sociologists and computing faculty on the team will help to understand, predict, and reduce barriers to competency-based employment of computing graduates from marginalized communities in the heart of the impoverished alabama black belt. the unique perspective relative to **\*\*diversity\*\***, equity, and inclusion needs should serve as a model for other computing departments. the third strand will develop competency-based surveys for practitioners and academics to identify and refine specific competencies that are hoped to drive continual curricular change. outcomes, including the change

process, national workshops, and experiences from the local process will help with transferability in the computing education community. in addition to informing curricula, the project will provide valuable data for educational researchers to help close the gap between employers and higher education. finally, as the competency approach to curricular design is relatively new in computing and engineering disciplines, lessons from this project will have the potential to transform curricular review and design in other stem disciplines. the nsf iuse: ehr program supports research and development projects to improve the effectiveness of stem education for all students. through the institutional and community transformation track, the program supports efforts to transform and improve stem education across institutions of higher education and disciplinary communities. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Finding an informed approach to oligonucleotide ligand screening to enable antiviral materials

Awardee: Georgia Tech Research Corporation

Amount: \$224,994.00

Abstract: part 1: nontechnical abstract: as bio-inspired ligands for various biological targets, aptamers present key promising advantages over antibodies including their low immunogenicity, animal-free generation, reversible denaturation, and longer shelf-life. moreover, while research and financial investments in therapeutic antibody development and manufacturing have clearly overshadowed that of aptamers, oligonucleotide ligands still hold promising potential as advantageous targeting and even inhibition agents for challenging viral targets whose rapid spread and mutation capabilities can unfortunately outpace traditional therapeutic developments. in the absence of a priori rules to identify potential binding motifs within a self-hybridized oligonucleotide for a non-nucleotide target, finding the right aptamer (or set of aptamers) for a particular target is a daunting search problem, much like finding the right move in a game of chess or go, largely because

the candidate sequence space is staggeringly large. thus, in the absence of any chemical guidelines, researchers traditionally choose instead to simply maximize the sequence **\*\*diversity\*\*** among candidate aptamers by employing screening libraries consisting of large heterogeneous populations (~10<sup>9</sup> or more) of random dna or rna sequence members in a resource-intensive screening process called selex (systematic evolution of ligands by exponential enrichment). here, the goal of the proposed work is to develop a pipeline of candidate dna aptamers for spike protein. to undertake this ambitious goal for this pilot project we will pioneer an integrated experimental and informatics approach to rapidly and reliably identify dna oligonucleotide ligands from informed, designer libraries for a viral protein target called the spike protein.      part 2: technical abstract:

research and financial investments in therapeutic antibody development and manufacturing have clearly overshadowed that of lesser known, oligonucleotide-based ligands called aptamers. aptamers, on the other hand, hold promising potential as advantageous targeting and even inhibition agents for challenging viral targets whose rapid spread and mutation capabilities can unfortunately outpace traditional therapeutic developments. in the absence of design rules, finding the right aptamer (or set of aptamers) for a particular target is a daunting search problem, much like finding the right move in a game of chess or go, largely because the candidate sequence space is staggeringly large. thus, in the absence of any chemical guidelines, researchers traditionally choose instead to simply maximize the size (~10<sup>9</sup> or more different sequences) of screening libraries in a resource-intensive, evolutionary screening process called selex (systematic evolution of ligands by exponential enrichment). to overcome these challenging technical and scientific bottlenecks inherent to this popular aptamer screening platform, we propose to pioneer an integrated experimental and informatics approach to rapidly and reliably identify dna oligonucleotide ligands from designer libraries for a viral protein target called the spike protein. the proposed integrated experimental/computational aptamer discovery approach is intentionally adaptable using a ?lessons-learned? approach to pave the aptamer discovery pathway for viral targets, particularly as viral strains readily mutate. this work will offer unique, multidisciplinary student training opportunities

in the experimental and computational aspects of the work. if successful the pis believe this pilot project will lay the fundamental groundwork for future accelerated bio-inspired ligand discovery to enable desirable bioactivity of materials systems. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: How are Flood Basalts Fed? A Textural Investigation of the Chief Joseph Dike Swarm

Awardee: Georgia State University Research Foundation, Inc.

Amount: \$218,153.00

Abstract: this award is funded in whole or in part under the american rescue plan act of 2021 (public law 117-2). flood basalts are the earth's most extensive expressions of volcanism. the eruption and emplacement of these voluminous magmas have been linked to global climate shifts and many extinction events. the columbia river flood basalts in oregon, washington, idaho, and nevada are the most recent and best-preserved example of this voluminous volcanic activity. it is believed that degassing during their eruption 17-14 million years ago influenced global temperatures. a key aspect to understanding magmatic systems is deciphering how the magma is transported from depth to surface. at the chief joseph dike swarm in oregon, a portion of the magmatic plumbing system of the columbia river flood basalts is preserved and exposed. while the transport mechanism for these magmas is well understood (i.e., sheet magmatism), the style and timing of magmatism is poorly constrained. namely, were the chief joseph dikes produced through single-pulse events or grown through time as a series of magmatic pulses where each of them contributed with tectonic deformation and degassing? detailing the mechanism of transport and emplacement could constrain the rates of surface deformation and volatile release during magmatism. this study will utilize relatively fast, simple, and resource-light methodologies that will inform us of the dike emplacement

and growth mechanisms by studying in great detail the crystal textures recorded in the dikes themselves. this team's research project was designed from the ground up as an unparalleled research experience for underrepresented minority (urm) undergraduate students who will be recruited to participate in the research and dissemination process. this research is built intentionally to contribute to making the geosciences a diverse, equitable, and inclusive discipline by promoting the development of future leaders and mentors for subsequent students in stem research and education. the program will benefit the urm student cohorts with the knowledge, motivation, and inspiration to pursue focused science careers to solve us-national and global challenges. this project will investigate the tectonomagmatic evolution of the columbia river flood basalts (crfb), as recorded within the chief joseph dike swarm (cjds). the team will develop and disseminate a technique that uses electron backscatter diffraction (ebbsd) to identify dike emplacement style using textural analyses. analyses of dike centers will be performed on a statistically significant number of dikes to meaningfully constrain the actual proportion of single-event and pulsed emplacement styles. dike-center textural analyses will be calibrated using field observations and a subset of detailed textural profiles collected across dikes to identify the overall cooling history. the information generated by the proposed work will address long-standing questions surrounding the generation of space to accommodate hundreds to thousands of dikes with considerable average thicknesses. this will impact future research by generating a detailed database of dike textures and morphologies that will allow future comparisons with other crfb dike swarm systems and cross-comparison with other dike swarms worldwide. results will provide insights into magma transport efficiency through the crust and the relationship between tectonics and magmatism. characterizing the textures of pulsed assembly of dikes or dikes that experienced sustained high reynolds number flow will add to our overall understanding of magmatic plumbing systems and their connection to mineralization zones and hydrothermal fields. furthermore, the project will create linkages with education organizations in the state of georgia. researchers will train and professionally develop six underrepresented minority (urm) student research scientists over three years. the project will broaden the participation of urms

in geosciences as we will fully leverage the existing student populations from historically black colleges and universities and minority-serving institutions in georgia. the program will benefit the urm student cohorts with the knowledge, motivation, and inspiration to pursue focused science careers to solve us-national and global challenges. more importantly, this research is built intentionally to make geosciences a diverse, equitable, and inclusive discipline. their mentoring experience is built around creating a welcoming environment with comprehensive guidance by relatable mentors and academic socialization, which have proven to be integrative tools for urms. they want to foment the extraordinary untapped talent that urm students bring to geosciences. to do this, researchers need to work towards transformative change in the way they plan their research. this team believes that their program design strives to bring justice, **\*\*diversity\*\***, and inclusion to the field of geoscience. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Digitization TCN: Extending Anthophila research through image and trait digitization (Big-Bee)

Awardee: University of Colorado at Boulder

Amount: \$217,080.00

Abstract: declining populations of bees impact plant-pollinator interactions in both natural and agricultural systems. while bees and other insects pollinate most wild plants, and are critical to sustain a large proportion of global food production, they are decreasing in both numbers and **\*\*diversity\*\***. our understanding of the factors driving these declines is limited because we lack sufficient data on the distribution of bee species, and on the behavioral and anatomical traits that may make them either vulnerable or resilient to human-induced environmental changes, such as habitat loss and climate change. fortunately, wild bees have been collected by researchers and deposited in natural history collections for over 100 years, retaining a wealth of associated attributes that can be extracted from specimen images. this project will digitally capture data and images from these historic specimens, develop tools to measure bee traits from these images, and generate a comprehensive bee trait and image dataset to measure changes through time. this will increase our understanding of specific traits that put bee species at risk of decline - a critical need for both sustaining our agricultural economy and the conservation of our natural resources. in addition, the large image datasets created by this project can be used for new artificial intelligence identification tools that will help improve our future pollinator observation and monitoring efforts. the big-bee thematic collection network (big-bee tcn) will create over one million high-resolution 2d and 3d images of bee specimens, representing over 5,000 worldwide bee species, including all of the major pollinating species of the united states. the big-bee network includes 13 institutions and partnerships with us government agencies. novel mechanisms for sharing image datasets will be developed and datasets of bee traits will be available through an open data portal, the bee library, for research and education. the big-bee project will engage the general public in research through community science via crowdsourcing trait measurements and data transcription from images. in addition, training and professional development for natural history collection staff, researchers, and university students in data science will be provided through the creation and implementation of workshops focusing on bee traits and species identification. all data resulting from this award will be shared with and

publicly available through the national digitized biocollections resource, [idigbio.org](http://idigbio.org). this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: NSF Postdoctoral Fellowship in Biology FY 2021: Spatially Resolving the Cellular Landscape of Arbuscular Mycorrhizal Symbiosis with *M. truncatula* and *D. epigaea*

Awardee: Tivey                      Trevor              R

Amount: \$216,000.00

Abstract: this action funds an nsf plant genome postdoctoral research fellowship in biology for fy 2021. the fellowship supports a research and training plan in a host laboratory for the fellow who also presents a plan to broaden participation in biology. the title of the research and training plan for this fellowship to trevor tivey is "using spatial rna-seq and endocycle analyses to spatially resolve the cellular landscape of arbuscular mycorrhizal symbiosis with *medicago truncatula* and *diversispora epigaea*". the host institution for the fellowship is the boyce thompson institute and the sponsoring scientist is dr. maria harrison. a broad **\*\*diversity\*\*** of plants and a limited group of soil fungi interact together in a type of association known as arbuscular mycorrhizal symbiosis. this underground relationship between plants and fungi takes place within plant root cells, and helps both plants and fungi acquire critical nutrients. key plant genes governing this symbiosis have been identified, however the timing and regulation of plant and fungal gene expression during colonization is complex and requires further understanding. to characterize this interaction, this project will measure plant and fungal transcripts during symbiosis at a fine spatial resolution and identify gene expression differences between cells along a gradient of fungal colonization. results from this project will help to develop resources for the study of root-microbe interactions and enable the application of these methods to address similar questions in major crops. in the process, this project will promote research participation of undergraduates who are underrepresented in biology and support students

from the local community through outreach and teaching. this project will use spatial mrna-seq to map the plant and fungal transcriptomes and compare gene expression in all plant cell types along a spatiotemporal gradient of colonization, enable the creation of plant-fungal gene co-expression networks, and correlate transcriptomic and microscopical evidence of endoploidy to identify candidate gene pathways. to address the controls on endoploidy, plant mutants, cell cycle markers, and image analysis will be used to disrupt symbiosis signaling and to examine the effects on endoreduplication. an increased understanding of the significance of endoploidy in am symbiosis has the potential to inform mechanisms of symbiotic and parasitic biotroph colonization in plants. spatial transcriptome datasets will be made publicly available in the ncbi gene expression omnibus. m. truncatula cell cycle marker lines and endocycle regulation mutants will be shared for future experimental studies of the plant cell cycle and biotrophic interactions. keywords: host-microbe, mycorrhiza, spatial transcriptomics, endoreduplication, colonization this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Amount: \$216,000.00

Abstract: this action funds an nsf plant genome postdoctoral research fellowship in biology for fy 2021. the fellowship supports a research and training plan in a host laboratory for the fellow who also presents a plan to broaden participation in biology. the title of the research and training plan for this fellowship to peter schafran is "leveraging frequent monoicy-dioicy transitions in hornworts to understand the rules of sex determination" the host institution for the fellowship is the boyce thompson institute and the sponsoring scientist is dr. fay-wei li. in animals sex determination is

fairly consistent across diverse groups, such as the xy chromosomes that originated once in the common ancestor of all placental mammals including dogs, cows, humans, elephants, whales, etc., over 166 million years ago. in contrast, the evolution of separate sexes in plants has occurred many times and over much shorter time periods. one plant group that shows this is hornworts, in which about half of all species have separate sexes that evolved from hermaphroditic ancestors at least 14 separate times. to understand why sexual system evolution is so flexible in plants, this project will examine how genes and chromosome structure change each time a species evolves to have separate male/female individuals. new genomes will be generated from hermaphroditic and male/female hornwort species representing over 300 million years of evolution in order to determine common genes that may be prerequisites for formation of separate sexes. this project will also examine patterns of change in genome architecture over time, as sex-determining genes eventually cause the formation of sex chromosomes, which then may be more likely to degrade. identifying these processes in hornworts will uncover mechanisms that may provide a model for evolution of separate sexes across all plants and a contrast for the starkly different pattern in animals. a better understanding of how chromosomes and genes function will enhance efforts to improve crop plants. this project will provide varied opportunities for training high school and undergraduate students in tissue culture, genome assembly, comparative genomics, and plant transformation. this project will leverage multiple monoicy-dioicy transitions across the hornworts in order to test whether common rules govern the evolution of sex-linked genes and sex chromosomes. evidence will be drawn from a broad range of phylogenetic **\*\*diversity\*\***, evolutionary time, genomic scales, and gene-phenotype associations. three specific objectives are: 1) characterize the structure and composition of hornwort sex chromosomes; 2) identify candidate sex-determining genes by examining genes associated with sex chromosomes and under selection in multiple lineages; 3) functionally characterize candidate sex-determining genes by transgenically over-expressing them in the monoicous model hornwort *anthoceros agrestis*. multiple genome assembly techniques will be used to create 19 new hornwort genomes representing monoicous and dioicous species assembled

to pseudochromosome level. genetic analyses will examine gene orthologs from pairs of monoicous and dioicous species to identify those with evidence of selection across multiple independent transitions between monoicy and dioicy. for genes found to recurrently appear to be selected for on sex chromosomes, their over-expression in *a. agrestis* is expected to affect the successful development gametes/gametangia and their ability to form viable sporophytes. the expected results will contribute functional knowledge about specific genes, and about the associated chromosome structural and compositional variations that lead to formation of sex chromosomes. all data will be publicly available through genbank as well as hornwortbase, a new platform for hornwort genomic analysis ([www.hornwortbase.org](http://www.hornwortbase.org)). results will be communicated through public lectures and open access publications. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: NSF Postdoctoral Fellowship in Biology FY 2021: Establishing parametric variability as a driver of plasticity across genotypes with diverse life histories ...

Awardee: Dale, Renee

Amount: \$216,000.00

Abstract: this action funds an nsf plant genome postdoctoral research fellowship in biology for fy 2021. the fellowship supports a research and training plan in a host laboratory for the fellow who also presents a plan to broaden participation in biology. the title of the research and training plan for this fellowship to renee dale is "establishing parametric variability as a driver of plasticity across genotypes with diverse life histories through a novel mathematical modeling framework". the host institution for the fellowship is the donald danforth plant science center and the sponsoring scientists are dr. ivan baxter and dr. shankar mukherji. changes in climate increase the frequency and severity of extreme environmental conditions. organisms with the ability to be flexible (?plasticity?)

can rapidly adapt to these changes. plants need to be especially flexible since they cannot move if their environment suddenly changes. identifying the mechanisms that allow flexibility is increasingly important. due to the amount of information needed to understand plasticity throughout the plant life cycle, models and computational approaches are needed. a new method is proposed to identify ways that plants are flexible using hundreds of plants coming from diverse environments. it is hypothesized that plants from extreme environments will be more flexible, with more modes of growth. modeling will be used to identify different modes of growth and understand the underlying mechanisms. the results could be used in plant breeding programs to improve crop resilience and the approach can be used to understand the growth of other species. the proposed research will provide the pi with training and development opportunities in mathematics (biological stochasticity), biology (quantitative genetics, ecology, and plant physiology), and computation (python coding and high-performance computing). the impact of this work will be broadened through the development and dissemination of an educational video game, intended to improve **diversity** and inclusion of under-represented individuals. the video game will introduce these concepts to high school students in a low-stress way, circumventing the negative social perceptions of math. a novel mathematical modeling framework will be developed to identify processes driving plasticity across hundreds of plant genotypes with diverse eco-evolutionary backgrounds. a family of mathematical models of plant physiology and growth processes will be applied. model parameters will be estimated using bayesian parameter estimation, providing parametric distributions within and between genotypes. this will provide a conceptual framework to understand plasticity by integrating mathematical, computational, and biological theory. processes driving plasticity have agricultural significance, as the ability of crops to adapt and respond to increasing environmental stress is paramount. model parameters will be mapped to genomic loci, which could be used in breeding programs to test model predictions that such loci will confer plasticity, and to improve crop plants. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: CPS: Medium: Collaborative Research: Demand Response & Workload Management for Data Centers with Increased Renewable Penetration

Awardee: University of California-Davis

Amount: \$215,805.00

Abstract: the confluence of two powerful global trends, (1) the rapid growth of cloud computing and data centers with skyrocketing energy consumption, and (2) the accelerating penetration of renewable energy sources, is creating both severe challenges and tremendous opportunities. the fast growing renewable generation puts forth great operational challenges since they will cause large, frequent, and random fluctuations in supply. data centers, on the other hand, offer large flexible loads in the grid. leveraging this flexibility, this project will develop fundamental theories and algorithms for sustainable data centers with a dual goal of improving data center energy efficiency and accelerating the integration of renewables in the grid via data center demand response (dr) and workload management. specifically, the research findings will shed light on data center demand response while maintaining their performance, which will help data centers to decide how to participate in power market programs. further, the success of data center demand response will help increase renewable energy integration and reduce the carbon footprint of data centers, contributing to global sustainability. the pis will leverage fruitful collaboration to eventually bring the research to bear on ongoing industry standardization and development efforts. the pis teach courses spanning networks, games, smart grid and optimization, and are strongly committed to promoting **\*\*diversity\*\*** by providing research opportunities to underrepresented students. built on the pis expertise on data centers and the smart grid, this project takes an interdisciplinary approach to develop fundamental theories and algorithms for sustainable data centers. the research tasks are organized under two well-coordinated thrusts, namely agile data center dr and adaptive workload management. the strategies and decisions of data center dr will be made based on the workload

management algorithms that balance quality of service and energy efficiency and determine the supply functions. the workload management algorithms will optimize quality of service under the electric load constraints imposed by dr accordingly. this project will make three unique contributions: (1) new market programs with strategic participation of data centers in dr, instead of passive price takers, (2) fundamental understanding of the impacts of power network constraints on data center dr and new distributed algorithms for solving optimal power flow with stochastic renewable supplies, and (3) high-performance dynamic server provisioning and load balancing algorithms for large scale data centers under time-varying and stochastic electric load constraints and on-site renewable generation.

Title: Quantum Correlations in Information Theory, Their Interplay, and Their Limitations

Awardee: University of Houston

Amount: \$215,000.00

Abstract: this project will advance mathematical knowledge of quantum information theory. this work is in line with quantum leap, one of the nsf's 10 big ideas. one of the goals of the quantum leap big idea is to develop next-generation quantum technologies. but any technological advancement has

usually been long-preceded through theoretical mathematical progress. this project deals with questions in quantum resource theory, in particular a theory of entanglement. quantum devices use quantum systems to encode and process information. these systems make it possible to harness the effects of purely quantum phenomena such as superposition (the ability of being in "two places" at once) and entanglement (strong connections between two parts of the system) to drastically increase the security and the speed of computational devices. because of entanglement two spatially separated particles can affect each other instantaneously, a phenomenon which was initially considered to be paradoxical, even by einstein. one of the best-known protocols - quantum teleportation - relies on entanglement to destroy a quantum state in one place and perfectly recreate it in another distant location. while entanglement became one of the most valuable resources in quantum theory, many attributes of its behavior remain unknown. the broader impact of this award is to promote progress, **diversity**, and access to science on all levels of society and to broaden participation from underrepresented communities in stem. the major broader impact goals are: 1) to enhance training of graduate students in quantum information at the university of houston; 2) to improve educational opportunities in stem for students in local middle-schools in the economically challenged neighborhoods; 3) to increase public education in stem and quantum information science. entanglement is only one quantifier of "quantumness" in a system. other measures include coherence, discord, and mutual information. entanglement theory has gained its strong mathematical footing in the 1990's, but a closely related coherence theory started only recently. this project will establish proper mathematical limits on and relations between these measures, unify them, and classify them. it is well-known that under certain parameters, entanglement and coherence are dual to each other, in a sense that coherence can be converted to entanglement via incoherent operations, and vice versa in the asymptotic limit. this project will investigate this relation for different entanglement and coherence measures. moreover, the principal investigator will develop and investigate properties of newly proposed correlation measures. a closely related question is the distinguishability between two quantum states. how well we can distinguish different

physical states determines how much information we can encode into a certain system and how quickly we can manipulate it. one of the main problems that this project will focus on is the continuity of these quantifiers, which is a natural property of any quantum system. in other words, if the states are close when measured by one of these distances, how close are they when measured by another? or how well can these states be distinguished? or what is the structure of states that are close to each other? this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: PurSUIT: Species diversity and evolution of parasitic microfungi

Awardee: Butler University

Amount: \$211,455.00

Abstract: fungi are essential to ecosystem functioning, occur virtually everywhere, and form complex relationships with diverse organisms including prokaryotes, algae, plants, invertebrates, vertebrates, and other fungi. nonetheless, fungi are the most undersampled and poorly documented major lineage of eukaryotes, even though total species estimates range conservatively from 1.5-6.1 million species. this uncertainty reflects numerous gaps in knowledge about fungal distributions, especially regarding range and extent of unculturable fungi, microscopic fungi (microfungi), parasitic fungi, and tropical fungi. this project will document **diversity** of fungi in two groups that represent major gaps in our knowledge: the first are unculturable microfungi that associate with insects, called labouls, and the other are unculturable microfungi that associate with plants, called rust fungi. members of labouls and rust fungi are expected to have profound effects on ecosystem health and functioning through both beneficial and harmful interactions with their animal and plant hosts. the research team will explore several global habitats in tropical and temperate regions that have not previously been surveyed for these fungi. it is expected that hundreds of new species will be discovered and

described during this project. in addition to enhancing the documented bio\*\*diversity\*\* on the planet, this project will resolve the ?tree of life? for both groups and use this information to resolve long-standing questions regarding the evolution of the fungi. broader impacts include graduate and undergraduate training, international workshops to enhance collaboration between us and local researchers, and outreach to the public through ?bat night? and ?roach hunt? field trips. these fungal lineages are being studied for several reasons: 1) both represent groups poorly documented from tropical world regions; 2) both represent groups that are not detected by commonly applied culture-based and high throughput sequencing efforts; 3) neither group has been resolved, phylogenetically, by application of multi-locus analyses of known species; 4) both represent obligately parasitic lineages that are rarely studied but expected to have profound effects on ecosystems; and 5) both are or are related to heteroecious fungi (requiring two different hosts), a phenomenon that is extremely rare in fungi. a complementary team of us and other global experts on these fungi, ranging from junior to senior scientists, have designed an experimental approach that includes standardized sampling strategies from tropical and extra-tropical regions with multi-locus phylogenetic, phylogenomic, comparative genomic, and statistical analyses to: 1) determine whether accurate estimates from obligate microparasitic fungi, not included in any other estimates, will affect overall fungi species estimates; 2) whether parasitic microfungi follow the reverse latitudinal gradient posited for other fungal groups; and 3) resolve long-standing unresolved phylogenetic nodes by the incorporation of ?missing? lineages. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Frameworks: Collaborative Research: Integrative Cyberinfrastructure for Next-Generation Modeling Science

Awardee: Consortium of Universities for the Advancement of Hydrologic Sci

Amount: \$211,356.00

Abstract: this project is designed to support and advance next generation, interdisciplinary science of the complexly interacting societal and natural processes that are critical to human life and well-being. computational models are powerful scientific tools for understanding these coupled social-natural systems and forecasting their future conditions for evidenced-based planning and policy-making. this project is led by the network for computational modeling in social and ecological sciences (comses.net). comses.net's science gateway promotes knowledge sharing among scientists and with the general public, and enables open, online access to sophisticated computational models of social and ecological systems. comses.net's partners in this project (the community surface dynamics modeling system and consortium of universities for the advancement of hydrologic science) also enable knowledge sharing and provide open, online repositories of models in the earth sciences. this project will enhance these science gateways and create online educational materials to make these critical technologies easier to find, understand, and use for scientists and non-scientists alike. by integrating innovative technology with training and incentives to engage in best practice standards, this project will stimulate innovation and **\*\*diversity\*\*** in modeling science. it will enable researchers to build on each other's work and combine it in new ways to address societal and environmental challenges. the cybertools and educational programs developed in the project will be openly accessible not just to research institutions but also to smaller colleges, state and local governments, and a broader audience beyond the science community. the project will give decision-makers and the data scientists who support them access to a larger and more varied toolkit with which to explore potential solutions to societal and environmental policy issues. a long-term aim of the project is to support an evolving ecosystem of diverse, reusable, and combinable models that are transparently accessible to anyone in the world. sustainable planetary care and management is a challenge that confronts all of humanity, and requires knowledge, histories, methods, perspectives, and engagement of researchers, decision-makers, and private citizens across the country and throughout the world. the project will develop an integrative

cyberinfrastructure framework (icf) to enable innovative next-generation modeling of human and natural systems, and build capacity in modeling science. it will support a set of activities that integrate the human and technological components of cyberinfrastructure. 1) software tools will be developed that augment model codebases with modern software development scaffolding to facilitate reuse, integration, and validation of model code. 2) the project will provide high-throughput computing (htc) resources for simultaneously running numerous iterations of models needed to capture stochastic variability, explore a parameter space, and generate alternative scenarios; 3) online training activities will build expertise and capacity to make effective use of the cybertools and the htc resources; 4) the icf will engage a global modeling science community to provide professional incentives that encourage researchers to adopt best practices and catalyze innovative science. leveraging existing nsf investments, the icf will be developed and deployed by the network for computational modeling in social and ecological sciences (comses.net), in partnership with the community surface dynamics modeling system (csdms), consortium of universities for the advancement of hydrologic science (cuahsi), open science grid, big data hub/spoke network, and science gateways community institute. computational models have emerged as powerful scientific tools for understanding coupled social-biogeophysical systems and generating forecasts about future conditions under a range of climate, biogeophysical, and socioeconomic conditions. comses.net, csdms, and cuasi are scientific networks, with online science gateways and code archives that enable open access to computational models for an international community of social, ecological, environmental, and geophysical scientists. however, the full value of accessible, well-documented models only can be realized if their code is also widely reproducible and reusable, with a potential for integration with other models. in order to confront critical challenges for understanding the coupled human and natural systems of today's world, modeling scientists also need htc environments for upscaling models and exploring high-dimensional parameter spaces inherent in representing these systems. the icf is designed to meet these challenges. by integrating technology with intellectual capacity-building, the icf will stimulate innovation and **\*\*diversity\*\*** in

modeling science by letting creative researchers build on each other's work more readily and combine it in new ways to address societal-environmental challenges we have not yet perceived. the tools and training resources will be openly accessible not just to leading research institutions but also to the many smaller colleges, state and local governments, and a broader audience beyond science. they will provide decision-makers and the data scientists who support them access to a much larger and more varied toolkit with which to explore potential solution spaces to social and environmental policy issues. the proposed icf is also designed to help transform scientific modeling practice, including incentives that can help early career researchers shift from creating models to solve problems specific to a particular project to models that are also useful for others. the project will help support a future evolving ecosystem of diverse, reusable, and integrable models that are transparently accessible to the broader community. this project is funded by the office of advanced cyberinfrastructure in the directorate for computer and information science and engineering, with the division of social and economic sciences in the directorate for social, behavioral & economic sciences also contributing funds. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: SPARC: Facilitating Research, Experimentation, and Education in Spatial Archaeometry

Awardee: University of Arkansas

Amount: \$209,726.00

Abstract: the spatial archaeometry research collaborations (sparc) program promotes the use of spatial analysis, 3d modeling, as well as satellite, aerial, and terrestrial remote sensing in archaeological research projects. the things archaeologists study?from artifacts to sites to landscapes?almost always have a spatial component and spatial analysis is therefore central to

contemporary archaeological investigations. today, the increasing availability and sophistication of geospatial technologies is not merely generating new data but is facilitating entirely novel means of engaging with the archaeological record and exploring the human past. however, the high costs of instrumentation and software, combined with the expertise they require, create hurdles for many archaeologists who aim to deploy geospatial technologies in research projects. sparc 1) facilitates high-impact spatial archaeometric research, 2) advances emerging methodologies towards greater community use, 3) promotes this new knowledge across the discipline, and 4) promotes inclusion of junior and underrepresented scholars and institutions in leadership roles and in its training schema. through its innovative approach to supporting collaborative archaeological research, the sparc program makes costly geospatial technologies and specialized domain expertise available to researchers from a wide range of backgrounds, including early career scholars and those at minority serving institutions, enhancing **\*\*diversity\*\***, equity, and inclusion within archaeological research. the program also provides education and training opportunities for students and professionals seeking to use geospatial techniques in their own research, broadening the impact of the program far beyond individual supported projects. the sparc program supports archaeological researchers seeking to integrate geospatial technologies and methods into their investigations by facilitating collaborations with research faculty and staff and the technological infrastructure from the university of arkansas' center for advanced spatial technologies (cast), dartmouth college's spatial archaeometry lab (sparcl), and the university of arkansas' microct imaging consortium for research and outreach (micro). researchers apply to the program through a competitive, peer-reviewed process, and successful proposals receive support from geospatial technologies experts in both field and lab settings, access to specialized equipment and software, and intensive training opportunities.

this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: EAGER: Collaborative Research: Enhancing Asian American and Pacific Islander Participation and Belonging in the Geosciences

Awardee: Brown University

Amount: \$209,243.00

Abstract: asian americans and pacific islanders (aapi) represent one of the fastest growing demographics in the u.s. today and yet lag in participation and representation in geoscience graduate programs compared to other stem fields. thus, new programs are needed that specifically recruit aapi stem undergraduates to geoscience graduate programs and enhance belonging of aapi geoscientists as a whole. the proposed activities will focus on minority serving institutions (msis) that serve aapi. this project will expose as many as 1,000 undergraduates from msis in geoscience-adjacent stem fields to geoscience research and careers, provide a new research internship opportunity and create national cross-career stage connections between aapi geoscientists to produce a cohort of geoscience leaders from a group often left out of \*\*diversity\*\* discussions. aapi scientists desire to relate their work to local populations and problems relevant to their communities; therefore, diversifying geoscience graduate programs with those identifying as aapi will have a direct impact on communities facing important geoscience problems of the 21st century such as climate change, natural hazards, and resource scarcity. this project supports pilot programs to enhance participation and belonging for asian american and pacific islander (aapi)

communities in geosciences. the proposed activities include: 1) establishing a researcher visit program to recruit undergraduate aapi into geosciences via visits to aapi-serving msis from geoscience researchers; 2) a pilot research internship program for undergraduates at these institutions to carry out research with aapi mentors; 3) organizing virtual and in-person events and a career development workshop to enhance belonging, identity, and leadership within the aapi geoscience community across career stages and sectors. the outcomes of this combination of the proposed activities will help to develop geoscience programs, and create a cohort and community of belonging, access, justice, equity, **\*\*diversity\*\***, and inclusion (bajedi) leaders of aapi geoscientists. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: EAGER: New superdiffusive pastes from self-motile active particles with extreme penetration capabilities enabling breakthrough biomedical technologies

Awardee: North Carolina State University

Amount: \$207,967.00

Abstract: this eager project will seek to prove the feasibility of new high-risk, high-reward, interdisciplinary ideas in the field of self-propelling active particles. these new classes of particles can convert their internal chemical energy, or energy from external fields, into motion. the motile particles have highly unusual properties and can form the basis of new biomedical products with very high efficiency and radically improved performance. however, the present types of active particles are complicated or require a special medium for propulsion. this project will explore new types of active particles, which will propel themselves by simple osmotic effects, while a portion of the particles dissolve in the medium. a new system made of such particles called a "superdiffusive paste" will have extraordinary properties in being able to rapidly permeate any medium with interconnected pores, infusing any crevice, pore, and cavity, as the motile particles move through

the pore network. this system could be used to deliver compounds in challenging situations. for example, a superdiffusive paste loaded with disinfectant will be able to penetrate the complex inner channel network of teeth and kill microbes concealed within this network. this eager project will explore new physical principles for particle self-propulsion without an external source of energy or special media and will apply these principles by constructing a new type of suspension in the form of a superdiffusive paste. the introduction of the superdiffusive paste could spark new areas of fundamental research due to the rich variety of mass-transport effects that will emerge in such novel active particle systems. the most exploratory and interdisciplinary element will be the application of the superdiffusive paste in biomedical systems. specifically, the project will seek to demonstrate that the high permeation capability of the superdiffusive paste can lead to future transformative products for disinfection of open teeth, tissues, and wounds. the development of the novel paste will be done in collaboration with experienced dental investigators. the broader impacts of the project include providing training ground for a new diverse group of engineering students in the emerging areas of active materials. these students will master multidisciplinary topics ranging from chemical engineering, to design of new active materials, to their translation to biomedical use. it will also contribute to the research team's ongoing activity in maximizing undergraduate and graduate researcher **\*\*diversity\*\*** and preparing enticing materials for hands-on outreach demonstrations. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: NSF Postdoctoral Fellowship in Biology FY 2021: Invaders from the sea: unearthing the genomic basis of marine-to-terrestrial life-history transitions

Awardee: Morgan                      Victoria      M

Amount: \$207,000.00

Abstract: this action funds an nsf postdoctoral research fellowship in biology for fy 2021, broadening

participation of groups underrepresented in biology. the fellowship supports a research and training plan for the fellow that will increase the participation of groups underrepresented in biology. since all life on earth began in the oceans, but most large species currently live on land, the fellow plans to study the genetic basis of sea-to-land transitions to better understand how these transitions, which have profoundly shaped modern bio\*\*diversity\*\* patterns on earth, may have happened long ago. using land crabs that spend part of their lives in aquatic habitats and the other part on land, the fellow will explore gene expression patterns between their juvenile aquatic and adult terrestrial life stages to identify which genes may be associated with their terrestrial metamorphosis. by comparing these patterns across multiple species, the fellow hopes to identify larger evolutionary patterns that might shed light on how life may have adapted to land millions of years ago. the fellow will also create a mentorship program that pairs postdoctoral students from diverse groups with faculty from similar backgrounds to provide them with successful role models and guidance during a critical career phase. the program will also provide professional development opportunities that will prepare the mentees for applying to and securing academic or industry jobs, which will help increase the participation of these underrepresented groups in biology.

the fellow will characterize the larval stages of three land crab species with different developmental modes, and then compare intraspecies gene expression between developmental stages, and interspecies gene expression across developmental strategies to determine which genetic shifts may have been important changes that allowed for lineages with more direct developmental modes to adopt highly terrestrially lifestyles. the findings from this project will provide insight into the nature of evolutionary predictability and its genomic underpinnings, as well as the genetic basis of major biological innovations and transitions. it will also generate novel genomic, transcriptomic, and developmental resources, and lay the groundwork for future studies that use transgenic tools and genome editing protocols to further investigate the genomic basis of convergently evolved terrestriality in this system. by undertaking this project, the fellow will develop new skills in embryology and comparative developmental transcriptomics. in addition to designing and

implementing her diverse mentorship program, the fellow will also directly increase **\*\*diversity\*\*** in biology since she is also from an underrepresented group. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: NSF Postdoctoral Fellowship in Biology FY 2021: Comparative viromics in vertebrates from the Sonoran Desert of the Baja California peninsula, Mexico and Arizona

Awardee: Vargas, Karla Leonor

Amount: \$207,000.00

Abstract: this action funds an nsf postdoctoral research fellowship in biology for fy 2020, broadening participation of groups under-represented in biology. the fellowship supports a research and training plan for the fellow that will increase the participation of groups underrepresented in biology. viruses play essential roles supporting life on earth. they are present in all environments and can affect all types of organisms. viruses are genetically and structurally diverse and their evolution is linked to their hosts. the fellow will characterize viral communities in wildlife and investigate host-virus dynamics in the sonoran desert. the natural variation of this region makes it the ideal setting to explore viral **\*\*diversity\*\*** associated with wildlife and the interactions between the host and the virus. this research is relevant to understanding factors that contribute to genetic variation within species, and also to understand how new species of viruses can emerge. furthermore, investigating undiscovered viral communities in wildlife may be instrumental to gain knowledge on emergence of new viruses and prevent potential spread to humans. this fellowship will support the research, training, and career advancement of a fellow from an underrepresented group in stem. the fellow will develop initiatives for underrepresented groups at the postdoctoral level, provide mentorship and develop educational tools. in collaboration with the nsf funded bajageogenomics consortium, the fellow will sample across the baja california peninsula, mexico (bcp), and the sonoran desert,

arizona (sda) and follow a viral metagenomics approach to a) characterize rna and dna viruses associated with host populations of rodents, lizards, and carnivores, b) compare viral \*\*diversity\*\* within bcp and sda host populations and evaluate potential geo-climatic and demographic predictors of viral \*\*diversity\*\*, and c) assess host-virus dynamics across bcp by investigating whether viral genomic differences are consistent with intraspecific genetic divergence between northern and southern populations. the project will integrate genomic and biogeographic data to fill fundamental gaps in viral \*\*diversity\*\* and explore the role of environmental stressors and host demographics in host-virus systems. the fellow will investigate the lineal history of host and viruses in context of the geo-climatic history of the region, predictors of viral richness, and patterns of divergence in viruses and hosts. as part of this appointment, the fellow will work along an international cross-disciplinary team, receive training in viral metagenomics methods, organize an international postdoctoral seminar series, initiate a virtual network for latinx postdocs, contribute to the development of bilingual educational videos, and promote science education and mentorship for k-12 students. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: NSF Postdoctoral Fellowship in Biology FY 2021: Color polymorphism: a model system for predicting phenotypic evolution in nature

Awardee: Brock, Kinsey M

Amount: \$207,000.00

Abstract: this action funds an nsf postdoctoral research fellowship in biology for fy 2021, integrative research investigating the rules of life governing interactions between genomes, environment and phenotypes. the fellowship supports research and training of the fellow that will contribute to the area of rules of life in innovative ways. climate change is expected to generate extreme environmental conditions, and our ability to predict the way organisms will respond to projected

environmental change is critically important for the future. in nature, thousands of species have evolved color polymorphism. that is where multiple distinct color morphs, that also differ genetically and behaviorally, coexist within the same species. color polymorphic species are an ideal system to develop predictive power in biology because often color morphs of the same species are associated with different aspects of the environment. the aim of this project is to identify repeatable associations between lizard color morph traits, genetics, and specific environmental variables that are expected to change with climate change (temperature, air moisture, precipitation, etc.) to develop predictions about how animals will evolve and adapt to changing environments. the fellow will use the aegean wall lizard, which has three color morphs: orange, yellow, and white, that differ by environment to study how color morph genetics and environmental change variables interact to produce different color morphs in different environments. the fellow will engage undergraduates underrepresented in the sciences in research as lab and field assistants. this project will also include an international outreach component that will communicate basic principles of evolution to elementary school children in the san francisco bay area, united states and athens, greece with art-based activities. this research will use genetically determined color morphs of the aegean wall lizard to identify gene-phenotype-environment interactions that have naturally produced repeated evolution of the same morph phenotypes in similar environments. this research will use color polymorphism as a model system to test for: predictable associations between intraspecific morph **\*\*diversity\*\*** and environmental variation, the evolution of repeated morph phenotype-environment associations in isolated populations, and correlated macroevolution of morph phenotypes and environmental variation across many color polymorphic species. the fellow will train in integrative approaches that combines adaptive landscape theory, genomics, computation, fieldwork, and experiments to identify predictable patterns of phenotypic evolution from complex interactions across biological scales. the fellow will engage undergraduates from underrepresented groups in research and science outreach activities with local and international elementary classrooms. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's

intellectual merit and broader impacts review criteria.

Title: Collaborative Research: GEOPATHS IN: DIG CAMP - Data in Geosciences: Collaboration and Mentoring Program?Teaming Latinx High School and College Students for Data Use in Geosciences

Awardee: University of California-Berkeley

Amount: \$206,815.00

Abstract: this award is funded in whole or in part under the American Rescue Plan Act of 2021 (Public Law 117-2). Atmospheric, climate, ocean, earth and environmental sciences (geosciences) are among the least diverse fields in science, technology, engineering and math (STEM), with Latinx scientists being significantly underrepresented. A lack of **diversity** in STEM fields means decreased ability to identify and solve critical issues facing society such as climate change, which disproportionately affects the populations that are least represented in STEM. Data literacy is gaining increasing relevance and importance to scientists and the general public as we aim to make informed decisions to solve locally and globally relevant problems. DIG CAMP (Data in Geosciences: Collaboration and Mentoring Program?Teaming Latinx High School and College Students for Data Use in Geosciences) offers a camp-based model to support engagement with geosciences, as well as data literacy. During this project and through its sustainability plan, DIG CAMP provides opportunities for Latinx high school students to engage with authentic and locally relevant geosciences research and data; gain geosciences content knowledge; build their data literacy, critical thinking, problem solving, and collaboration skills; strengthen their identities to do science; and increase the likelihood that they will pursue academic or workplace careers in the geosciences. DIG CAMP - Data in Geosciences: Collaboration and Mentoring Program?Teaming Latinx High School and College Students for Data Use in Geosciences will broaden participation in the geosciences among communities of color by developing a research-based model for overcoming long standing barriers and biases within

the field. the goals of this project are to: (1) design and implement a complementary suite of informal learning experiences to actively recruit latinx high school students into the geosciences by increasing their engagement, capacity building, and opportunities for continuity in the discipline; (2) provide latinx undergraduate geosciences majors with meaningful outreach and mentoring opportunities that engage them with communities, and increase their retention in geosciences fields of study and careers; and, (3) support high school students and their undergraduate mentors to build science and data literacy skills and engage with locally relevant geosciences research data to increase their efficacy and success in college and the geosciences workforce. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: From Quantum Droplets & Spinor Solitons to Vortex Knots & Topological States: Beyond the Standard Mean-Field in Atomic BECs

Awardee: San Diego State University Foundation

Amount: \$201,843.00

Abstract: the realm of bose-einstein condensates (becs) was originally proposed as a curious feature of the statistical properties of atomic particles with integer spin by bose and einstein in the 1920's. this consisted of the condensation of the excited states particles into the ground state of the system and the formation of a macroscopic, coherent "super-wave" therein, allowing the study and observation of quantum mechanical properties beyond microscopic scales. however, the temperatures needed for its experimental realization were so low that it took about 70 years for e.a. cornell, w. ketterle, and c.e. wieman to realize becs in the lab. the importance of this feat was recognized only a few years later via the 2001 nobel prize in physics. this has, in turn, enabled a pristine platform where numerous exciting features of nonlinear dynamics of waves and coherent structures can be studied and experimentally observed. importantly, these coherent structures are

also of wide applicability in numerous other areas of physics including, most notably, nonlinear optics, plasma physics, and water waves. within atomic physics, becs have also been fundamental toward the study of remarkable quantum features such as superconductivity and superfluidity and, in that capacity, they have been front and center toward the experimental discoveries connected to the vortices and their lattices cited in the 2003 nobel prize in physics and the topological phases and their transitions associated with the 2016 nobel prize in physics. the aim of this project is to advance the state-of-the-art at this exciting nexus of atomic physics theory, physical bec experiments, applied mathematical analysis, and the forefront of scientific computing, while at the same time training a new generation of scientists and mathematicians at this scientific interface and transcending disciplinary boundaries. in line with the past trajectory of the pis, an emphasis on the **\*\*diversity\*\***, equity and inclusion of under-represented groups will be sought within this research effort. more concretely, the principal thrust of the present project consists of the study of non-trivial extensions of standard bec settings. in particular, the main axes of the proposal consider the following themes. (1) two-component mutually attractive becs that allow, through quantum corrections and the famous lee-huang-yang (lhy) contribution, for the highly timely formation of so-called quantum droplets. the key realization for such droplets is that their emergence stems from the interplay between repulsive mean-field and attractive beyond-mean-field contributions. (2) three ( $f=1$ ) and five ( $f=2$ ) spin component settings supporting symbiotic (dark-antidark and dark-bright) solitary wave structures with unprecedented integrable or weakly non-integrable properties. (3) 3d vortex knot structures in one and multi-component/spinor settings. vortex knots constitute one of the most elusive types of vortical structures for which limited experimental and theoretical analysis exists. the pis will also explore in the spinor settings complex non-trivial topological patterns such as alicia rings and dirac monopoles. (4) topologically nontrivial toroidal trapping settings, where the interplay of the intrinsic metric and curvature of the system with the effective nonlinearity can yield unprecedented coherent structures and dynamics thereof. more broadly within this theme, the pis will study nonlinear waves such as solitons and vortices confined on different types of curved surfaces. this ambitious program

should push the boundaries of the state-of-the-art mean-field-theoretic understanding, offering numerous beyond-mean-field insights and elucidating their range of validity as well as the interplay of nonlinearity with quantum, as well as thermodynamic effects. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Audio for Inclusion: Uncovering Marginalized Student Narratives to Provide Insight to Faculty on the Known Unknowns of Inclusion

Awardee: Utah State University

Amount: \$200,982.00

Abstract: this project will bring the experiences of diverse engineering students directly to faculty through edited audio interviews. undergraduate engineering education is a critical juncture in the diversification of the engineering workforce. however, engineering educational culture can marginalize many groups. faculty are key change agents in this culture, and their empathy and understanding for diverse students are critical for enabling and promoting inclusive education. however, faculty may not be aware of diverse student perspectives, and even well-intentioned faculty may fall short of creating inclusive classroom environments. more resources are needed to help develop faculty empathy and understanding for a broad range of student populations in engineering education. qualitative research presents a promising tool for centering the voices and experiences of students, but researchers' typical long form journal publications for disseminating qualitative research are not an accessible and compelling medium. to increase collective impact, more accessible, innovative, and timely dissemination strategies are needed. podcasts and youtube clips can be used to disseminate research findings with more immediacy and personalization than written text. in this study, we will feature these audio formats as media to share diverse student experiences with faculty and to facilitate a broader impact on pedagogy and culture. faculty who listen to the audio will have the potential to gain reflective awareness of student experiences that provoke the creation of more inclusive classrooms. this novel dissemination approach will be sustained through the creation of a widely distributed podcast called audio for inclusion, hosted by the pis. this podcast will include the final versions of edited audio files generated in this study and will be located on the asee \*\*diversity\*\* committee's web and youtube pages, and incorporated into

workshops. we will conduct a nationwide recruitment of students with salient minoritized identities via email distributed through relevant organizations, campus support centers, and snowball recruitment. twenty (20) students will be interviewed twice throughout the duration of the study using a semi-structured protocol that focuses on their experiences in engineering education. interviews will be transcribed, de-identified, edited for conciseness, and re-recorded by student actors. recorded interviews will be disseminated using a survey distributed to 100 faculty members who represent a range of familiarity with \*\*diversity\*\* and inclusion topics. this survey will prompt faculty participants to listen to embedded student narratives and provide feedback using likert-type and open-ended response questions. survey results will be used to observe the impact of the audio resources on faculty views of \*\*diversity\*\*, equity, and inclusion in engineering. this project will be informed by existing theoretical frameworks such as intersectionality, figured worlds, narrative, and critical theorizing. findings from this work will contribute to the knowledge base on broadening participation in engineering in three ways: (1) by providing insights into the experiences of students belonging to minoritized identity groups; (2) by developing an accessible resource for improving faculty knowledge of and strategies for promoting the inclusion of students? undisclosed identities and experiences in engineering education; 3) by establishing a novel research approach to broaden participation in engineering; (4) by employing innovative dissemination techniques that expand the impact of student participant voices; and (5) by contributing to evidence-based foundations for the future development of faculty-centered support structures related to expanding concepts of \*\*diversity\*\* and inclusion. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Improving First-to-Second Year Retention and Closing Equity Gaps through a STEM Academy

Awardee: Columbia Basin College

Amount: \$200,000.00

Abstract: this project aims to improve academic outcomes for hispanic students by creating and piloting a new stem academy which will offer a combination of financial, academic, and social supports to an initial cohort of students. such supports are ultimately expected to result in an increase in the number and **\*\*diversity\*\*** of stem graduates. columbia basin college has consistently had high levels of attrition for first year stem majors, particularly for low-income, first generation, and hispanic students, with only a little more than half (54%) of these students persisting into their second year. through the development of the new stem academy, this project will increase first-to-second year retention rates in the school of math, science, and engineering, and seek to close the school's retention equity gaps with respect to hispanic students. the goals of the stem academy project are to: 1) increase participants' first-to-second year retention by at least 12%, and 2) reduce the retention equity gap by at least 50%. towards that end, the project team will develop a new, cohort-based stem academy of 25-35 students for the pilot year. students in the academy will receive supports including direct financial assistance, reserved enrollment in linked courses, and a new dual-language orientation course specifically designed for stem students. stem academy participants will also benefit from intrusive academic advising, partnership with a peer mentor, and direct access to stem professionals via an industry-led stem colloquium. these high-impact practices are specifically geared toward increasing students' sense of belonging and self-efficacy in stem subjects, which will improve student persistence during the critical transition from the first year to the second year of their postsecondary education. this will result in a larger and more diverse body of students who will be academically prepared to meet the growing needs of the stem workforce. the hsi program aims to enhance undergraduate stem education, broaden participation in stem, and build capacity at hsis. achieving these aims, given the diverse nature and context of hsis, requires innovative approaches that incentivize institutional and community transformation and promote fundamental research (i) on engaged student learning, (ii) about what it takes to diversify and increase participation in stem effectively, and (iii) that improves our understanding of how to build

institutional capacity at hsis. projects supported by the hsi program will also draw from these approaches to generate new knowledge on how to achieve these aims. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: HSI Pilot Project: Broadening Research Experiences for HSI STEM Diversity, Equity, and Inclusion (BREDEI)

Awardee: Texas A&M University-San Antonio

Amount: \$199,999.00

Abstract: with support from the improving undergraduate stem education: hispanic--serving institutions (hsi program), this track 1 project aims to improve the quality, availability, and **\*\*diversity\*\*** of the stem educational pipeline. by building a sustainable undergraduate field research program at texas a&m university--san antonio, the project will develop a strong scientific and professional identity critical to the persistence in stem majors and the motivation to pursue a science--related career. we will develop role models, facilitate student participation in federally--supported research projects, and provide field training programs to heighten the scientific literacy and identity among the participating students. as the project team validates the impact of these practices and develops them into a curricular program, the project will have a long--term impact of cultivating reliable domestic talent from underrepresented populations by improving the disproportionately low representation of hispanic students in south texas in the aquatic ecology profession. aquatic sciences are highly interdisciplinary and require a considerable amount of field experience that has not always been accessible to under--represented student groups. we hypothesize that improving the availability of field research opportunities and role models are key to the success of minority stem majors. thus, the specific aims of the project are to (1) improve scientific literacy among minority communities, (2) broaden undergraduate research experiences

focusing on assessing the health of stream ecosystems, (3) improve recruitment, retention, and graduation of minority students by offering field research and mentoring programs, and (4) establish a sustainable model for a field--heavy curriculum via a collaborative model between hsis, schools, public and private sector entities. these objectives will be achieved by implementing field--training activities supported by the national ecological observatory network (neon), the national hispanic environmental council (nhec), and the texas aquatic science project. the outcome of the project will enable the development of a university faculty-reviewed field--study curriculum for a&m--sa that will benefit students from multiple natural resource majors. the hsi program aims to enhance undergraduate stem education, broaden participation in stem, and build capacity at hsis. achieving these aims, given the diverse nature and context of the hsis, requires innovative approaches that incentivize institutional and community transformation and promote fundamental research (i) on engaged student learning, (ii) about what it takes to diversify and increase participation in stem effectively, and (iii) that improves our understanding of how to build institutional capacity at hsis. projects supported by the hsi program will also draw from these approaches to generate new knowledge on how to achieve these aims. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Catalyst Project: STEM-Business Focused Sustainable Financial Technology ? Clean Technology (Sustainable FinTech-CleanTech) at the University of the District of Columbia

Awardee: University of the District of Columbia

Amount: \$199,997.00

Abstract: catalyst projects provide support for historically black colleges and universities to work towards establishing the research capacity of faculty to strengthen science, technology, engineering and mathematics undergraduate education and research. it is expected that the award will further the faculty member's research capability, improve research and teaching at the institution, and involve undergraduate students in research experiences. this project at the university of the district of columbia (udc) includes support for the development of a financial technology-clean technology certificate. the proposed work has the potential to establish partnerships with other higher education institutions and the local k12 system. it is expected that participating students will contribute to increasing **\*\*diversity\*\*** in the fintech-cleantech workforce. the overarching goal of the stem-business focused sustainable financial technology ? clean technology (sustainable fintech-cleantech) project at the udc is to introduce and provide business and engineering undergraduate students at udc with an innovative and interdisciplinary ?sustainable fintech-cleantech? certificate program available to both business as well as science, technology, engineering and mathematics (stem) majors. specific objectives of the project are: (1) to develop an innovative and interdisciplinary sustainable fintech-cleantech certificate program open to business and stem undergraduates; (2) to enrich and enhance undergraduate student and faculty research

capacity in fintech-cleantech curriculum; and (3) to engage udc students in sustainable fintech-cleantech certificate program through outreach to local high schools and community colleges. the project will utilize a mixed-method approach that emphasizes student surveys, observations, focus groups, and interview protocols for assessing the desired project outcomes. the potential contribution and impact of the project include the development of a cutting-edge fintech-cleantech certificate program for engineering and business undergraduates at udc, an hbcu, leading to the participation of underrepresented groups in this discipline; enhancement of education and research in diverse focus areas by developing instructional materials for enterprise applications (e.g., enterprise resource planning software by sap through sap university alliances program) that can be modeled at other institutions; research collaborations among students and faculty from underrepresented groups; leveraging and building udc's partnerships with academia, industry, and government; and dissemination of project results to the broader community by presenting and publishing project outcomes in peer-reviewed conferences and scholarly journals. the institution-wide fintech-cleantech certificate program has the potential of benefitting engineering and business students and providing a validated replicable model for other similar institutions in the nation. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Abstract: catalyst projects provide support for historically black colleges and universities to work towards establishing the research capacity of faculty to strengthen science, technology, engineering and mathematics undergraduate education and research. it is expected that the award will further

the faculty member's research capability, improve research and teaching at the institution, and involve undergraduate students in research experiences. this project at the university of the district of columbia (udc) includes support for the development of a financial technology-clean technology certificate. the proposed work has the potential to establish partnerships with other higher education institutions and the local k12 system. it is expected that participating students will contribute to increasing **\*\*diversity\*\*** in the fintech-cleantech workforce. the overarching goal of the

stem-business focused sustainable financial technology ? clean technology (sustainable fintech-cleantech) project at the udc is to introduce and provide business and engineering undergraduate students at udc with an innovative and interdisciplinary ?sustainable fintech-cleantech? certificate program available to both business as well as science, technology, engineering and mathematics (stem) majors. specific objectives of the project are: (1) to develop an innovative and interdisciplinary sustainable fintech-cleantech certificate program open to business and stem undergraduates; (2) to enrich and enhance undergraduate student and faculty research capacity in fintech-cleantech curriculum; and (3) to engage udc students in sustainable fintech-cleantech certificate program through outreach to local high schools and community colleges. the project will utilize a mixed-method approach that emphasizes student surveys, observations, focus groups, and interview protocols for assessing the desired project outcomes. the potential contribution and impact of the project include the development of a cutting-edge fintech-cleantech certificate program for engineering and business undergraduates at udc, an hbcu, leading to the participation of underrepresented groups in this discipline; enhancement of education and research in diverse focus areas by developing instructional materials for enterprise applications (e.g., enterprise resource planning software by sap through sap university alliances program) that can be modeled at other institutions; research collaborations among students and faculty from underrepresented groups; leveraging and building udc?s partnerships with academia, industry, and government; and dissemination of project results to the broader community by presenting and publishing project outcomes in peer-reviewed conferences and scholarly journals. the

institution-wide fintech-cleantech certificate program has the potential of benefitting engineering and business students and providing a validated replicable model for other similar institutions in the nation. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: HSI Pilot Project: The MAESTRO Program - Minority Advancement in Engineering, Science, and Technology by Refactoring the Online Program

Awardee: CSUB Auxiliary for Sponsored Programs Administration

Amount: \$199,993.00

Abstract: with support from the improving undergraduate stem education: hispanic-serving institutions (hsi program), this track 1: ppp aims to address the lack of means and support for hispanic/latinx, low-income, first generation students to effectively participate in postsecondary education. modern students work while going to school. for hispanic/latinx students who work twenty to forty hours a week, this workload may affect attendance and gpa, ultimately resulting in poor workforce placement. addressing the issue that work comes first for many low-income underrepresented students, two approaches will be utilized: 1) supplant non-career-relevant work experience with industry internships, and 2) develop new formats for online learning. the overarching theme is to help students maintain both their income and academics. busy students often turn to online programs that can be as effective as face-to-face instruction when combined with online videos and peer instruction. however, this model dichotomizes at-risk students due to poor regulation and social interaction. preliminary results show that this classroom model does not improve outcomes or attitudes of california state university- bakersfield (csub) students. a system that scaffolds and regulates the class with small groups convened at times around student work will be pioneered. significant, meaningful experiences will be offered for students in data science and wireless communication. participants of this program will have career-relevant internship/work

experience, better retention rates, shorter timelines to graduation, reduced stress, and better motivation. it will contribute to the size and **\*\*diversity\*\*** of the u.s. science and technology workforce. this project will utilize real-time teaching where students proceed at their own pace. the instructor monitors, scaffolds, and self-regulates the class by convening small groups at times convenient to the students for semi-synchronous learning. this approach will be paired with industry internships relevant to careers in computer engineering (ce), computer science (cs), and electrical engineering (ee). the impact of these strategies and how they improve the retention and success of the hispanic/latinx, low-income, and/or non-traditional students in ce, cs, and ee will be assessed. findings will be disseminated broadly through various presentations at conferences, publications, workshops and a project website. the hsi program aims to enhance undergraduate stem education, broaden participation in stem, and build capacity at hsis. achieving these aims, given the diverse nature and context of the hsis, requires innovative approaches that incentivize institutional and community transformation and promote fundamental research (i) on engaged student learning, (ii) about what it takes to diversify and increase participation in stem effectively, and (iii) that improves our understanding of how to build institutional capacity at hsis. projects supported by the hsi program will also draw from these approaches to generate new knowledge on how to achieve these aims. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: EAGER: Discovering the hidden functional trait diversity of Bees (Apoidea) and predicting functional diversity impacts on rendered ecosystem services

Awardee: LAWRENCE UNIVERSITY OF WISCONSIN

Amount: \$199,957.00

Abstract: we often associate pollination with a few external characteristics in bees (e.g., hairiness & tongue length) but bees are complex organisms with a plethora of unstudied morphological and

physiological traits (e.g., gut structure, muscular form, and thermal tolerance) that can strongly influence their effectiveness as pollinators. this project will link unstudied, internal morphological traits with bee physiological responses. at its core this work links structure and function with the functional role of bees as pollinators. microct technology will be used to render high-resolution quantitative imagery of internal morphological traits. honeybees will be used as a model system and the work will be expanded to obtain imaging and an analytical framework of 50 species of wild bees across multiple groups. by linking morphology and physiology with functional **\*\*diversity\*\***, this work has the potential to shape how we think about and manage pollinator bio**\*\*diversity\*\***. this work will provide research and training opportunities to six undergraduate students that will work on microct imaging techniques, biological data science and experimental biology on the physiology of bees. this project will explore the associations between functional **\*\*diversity\*\*** and morphological and physiological traits that directly influence the ecosystem service of pollination provided by bees. the project uses microct technology to image both honeybees and native wild bees over the course of two years. specific emphasis is placed on internal morphological traits in relation to bee's physiological responses (e.g., respiration and thermal tolerance) to environmental stress and thus ultimately impact a bee's efficacy as a pollinator. the pi and undergraduate research assistants will conduct thermal tolerance and respiration assays on bees to determine potential links of functional trait morphology with important physiological responses. this work will provide workforce development opportunities. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Catalyst Award: Targeted Infusion Project: Advancing STEM Education Through Transportation Studies (TIP-ASETTS)

Awardee: North Carolina Agricultural & Technical State University

Amount: \$199,938.00

Abstract: catalyst projects provide support for historically black colleges and universities to work towards establishing the research capacity of faculty to strengthen science, technology, engineering, and mathematics undergraduate education and research. it is expected that the award will further the faculty member's research capability, improve research and teaching at the institution, and involve undergraduate students in research experiences. this project at north carolina agricultural and technical state university (nca&t) intends to create a digital badging program for students interested in the transportation industry. the proposed work has the potential to increase student skillsets to increase competitiveness for technical opportunities in the transportation industry and increase **\*\*diversity\*\*** in the transportation field. it is the intent to position the proposed work in the p21 framework which focuses on equipping students with the skills they need to succeed in school and their careers in the 21st century. the goal of the advancing stem education through transportation studies (asetts) digital badge program is to advance knowledge and understanding within stem education through activities designed to increase the number of highly skilled nca&t undergraduate students entering the transportation workforce. this goal will be achieved by using the following approach: (a) creating a stackable-units digital badge program that encourages undergraduate students to increase their skillsets along various dimensions such as life/career, innovation, technology, and core subject matter skills; (b) increasing the number of undergraduate students participating in transportation research experiences and other engaging activities that will expose students to career opportunities in transportation; (c) establishing a professional-to-student and student-to-student mentorship program, and (d) updating current courses by including activities designed to develop specific competencies needed in the transportation workforce. a successfully implemented program has the potential to serve as a case study through which the ability of a stackable-units digital badge program to increase students' engagement in educational activities will be evaluated. by focusing on students across different stem majors, the proposed program will be unique and novel in that it will develop students' competitive skillsets such as initiative and

self-direction as well as introduce them to transportation innovations and technologies. the research projects intend to cover diverse topic areas within the transportation domain including transportation demand management, optimization, emerging technologies, and human factors. finally, through the integration of the p21 and experiential learning components in transportation courses along with the mentorship activities, the asetts program aims to innovate existing curricula and provide a much-needed support network to facilitate the success of students underrepresented in stem disciplines who desire a career in the transportation industry. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Research Initiation: Understanding Teamwork Experience and its Linkage to Engineering Identity of Diverse Students

Awardee: San Francisco State University

Amount: \$199,919.00

Abstract: this project focuses on engineering identity (ei), which measures how strongly a person identifies with being an engineer and serves as an indicator of persistence and retention in engineering. the project is aligned with the goals of the research initiation in engineering formation program by investigating how teamwork explains or is explained by ei among undergraduate engineering students and to support a community of new researchers conducting engineering education research. repeated calls from engineering employers and educational accreditation bodies have stressed teamwork training in undergraduate education. this emphasis has led to a proliferation of studies on how teamwork promotes metacognitive ability, communication, and related skills. however, less is known about how teamwork informs or is informed by the ei of students from diverse backgrounds. the connection between team-based experiences and engineering identity is instrumental to inclusive teaching and learning because ei may be

disproportionately lower for some students. in addition, teamwork designed without considering ei may further exacerbate that gap. although more students from diverse backgrounds are entering engineering programs, the challenges they face in performance expectations, resource access, and peer interactions still hamper their retention and advancement. in a university context, these challenges are most clearly manifested in student teams. this grant will: (1) analyze teamwork experience through the behaviors of and disagreement patterns between team members in a student population with high social and economic **\*\*diversity\*\***; and (2) evaluate how teamwork informs ei. disagreement patterns will be depicted by the variation in team members' views on basic team constructs (task, process, satisfaction, cohesion, and relationship). grounded in dispersion theory, this project will employ a mixed-methods approach to understand the prevalence and disagreement patterns, illuminating how ei, gender, and other student-specific variables (demographics, transfer student, etc.) explain the likelihood of a student to disagree on tasks, process, and other teamwork constructs. the results have the potential to reveal gaps or equity issues. moreover, by leveraging survey instruments that have been tested by prior nsf-funded work, this project will explore how teamwork experience, via a lens of behaviors and disagreement pattern, relate to ei. thus, providing evidence on which behaviors are linked to stronger ei and which types of team dynamics (disagreement patterns) promote ei development when a disagreement occurs in teamwork. the project will develop a more robust model to effectively handle likert-style variables on ei. it addresses new questions that are expected to shape future work on inclusive teamwork design and interventions, while illuminating the gains in estimation accuracy as a result of the use of the new model with codes written in an open-source program to facilitate dissemination. this project will acquaint three early- and mid-career faculty members with new methods in engineering education research. by leveraging teamwork experiences to strengthen the ei of diverse students, they will be able extend this research to many inclusive learning or teaching endeavors. this work will take place at a hispanic-serving institution, where improvements in the curriculum and student experience in team-based coursework will lead to improved learning experiences for a diverse student body. this

award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: EAGER: Chronological context of species loss in a Caribbean vertebrate community

Awardee: Rutgers University Newark

Amount: \$199,839.00

Abstract: today's bio\*\*diversity\*\* crisis is underscored by species loss at a rate many times higher than expected based on the fossil record. it is estimated that since 1500 ce about 61% of species extinctions and 37% of all critically endangered species have been confined to islands. factors such as environmental variability and direct human impacts, such as habitat destruction and overhunting, are among the top threats to insular species. species losses caused by these increased pressures may disrupt biotic communities and affect their function in the long term. understanding how these factors affect bio\*\*diversity\*\* and why some species survive while others become extinct is important to devise strong policies for bio\*\*diversity\*\* conservation in the face of environmental change. the aim of this research is to examine past and present changes in the island vertebrate communities of hispaniola and puerto rico to investigate how species responded to different factors before and after the arrival of humans. by combining data from well-preserved fossils and modern communities, this study will target the following questions: what is the timeline of change in each island community? does species loss vary with the characteristics of each island? what members of each island community persist or were lost over time? what factors contributed to species loss? the answers to these questions will provide an opportunity to contextualize losses and community change across time and learn from these processes to help mitigate bio\*\*diversity\*\* loss today. this research will train undergraduate students, many of whom are from underrepresented groups in science; promote local scientific literacy via outreach; and benefit society by providing information about bio\*\*diversity\*\* change. through a detailed chronological study of the changes in vertebrate

communities, this project will provide a basis for predicting species responses to factors related to past environmental variability, human colonization history, and island and species characteristics. the primary focus will be on a comparative analysis of bat communities between islands, however fossilized remains of other vertebrates will also be quantified, in light of theoretical expectations of island biogeography. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: RAPID: The Impact of Bans on Peremptory Challenges On Voir Dire, Jury Composition, and Case Outcomes

Awardee: Arizona State University

Amount: \$199,750.00

Abstract: despite decades of effort aimed at reducing disparities in the american legal system, they persist. certain demographic groups are overrepresented in prisons and among those falsely convicted, due, in part, to their continually being underrepresented on juries. increased **\*\*diversity\*\*** on juries improves the quality of deliberation and reduces bias in jury decisions?but prosecutors? use of peremptory challenges is a primary mechanism for creating disparities on juries. prosecutors strike jurors from some groups at higher rates and successfully provide neutral reasons when challenged. arizona is about to take a truly transformative step by banning peremptory challenges, a ground-breaking reform taking effect on january 1st, 2022. the stated goal of the ban is to combat bias in jury selection; the assumption being that this will increase jury **\*\*diversity\*\*** and reduce bias in verdicts. this project advances basic science on **\*\*diversity\*\***, group decision-making, and combating bias in a real-world setting. it tests whether a structural change to the jury selection process alters how jury selection decisions are made and the downstream consequences for **\*\*diversity\*\*** and bias on juries. it tests whether racial discrimination in jury selection persists because attorneys shift their

tendency to offer compelling neutral justifications for excluding jurors of some groups from peremptory challenges to challenges for cause. this project furthers nsf values of combating bias and promoting equity, **diversity**, and inclusion by testing the impact of a large-scale ground-breaking intervention designed to do just that in the legal system. this project also creates important databases for future research and involve many members of underrepresented groups as research assistants in every stage of the research. this rule change presents an important and ephemeral opportunity to collect data on voir dire practices, composition of juries, and case outcomes before and after this change. this transdisciplinary, multi-method project is designed to achieve the following research aims: (1) test whether superior court juries are significantly more diverse and representative after the peremptory challenge ban, (2) test whether conviction or liability rates in cases with defendants of some groups will significantly decrease after the peremptory challenge ban, (3) test whether the percentage of persons of some groups excused for hardship/cause will significantly increase after the peremptory challenge ban is enacted, thereby mitigating the overall impact of the ban, (4) test whether the way challenges for cause are argued and decided in court changes after the peremptory challenge ban is enacted in ways that mitigate the overall impact of the ban, and (5) conduct interviews with judges and attorneys regarding how they might alter their jury selection strategies in ways that limit the impact of the ban on overall jury composition. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: MRI: Acquisition of a Micro-Transfer Printer for Heterogeneous Integration of Electronic/Photonic Microsystems

Awardee: Rochester Institute of Tech

Amount: \$199,500.00

Abstract: micro-transfer printing ( $\mu$ tp) is a recently developed technique that enables the integration of various micro-device technologies that cannot be easily manufactured on a common substrate. for example, laser light sources could be integrated onto a silicon photonics chip rather than fiber coupled. this proposal requests funds for the acquisition of an x-celeprint (xdc)  $\mu$ tp system well suited for research and development, and prototype fabrication, with the capability of seamless technology transfer to pilot-line or high-volume production using larger xdc automated systems. the proposed instrument will support next-generation research activities in technology areas such as display devices, computing, energy conversion, quantum photonics, 2d materials, and biosensors. results from the supported research will provide significant contributions to the literature in relevant and emerging scientific fields. participants will include graduate and undergraduate student researchers in several disciplines of engineering and science, with a particular emphasis on **\*\*diversity\*\*** and inclusion. the proposed investigations will advance scientific knowledge and support activities that contribute to the betterment of society. these include preparing a diverse workforce for next-generation engineers and scientists, outreach activities with k-12 programs in the rochester, ny region to promote stem, and professional development opportunities for high school

teachers and industry partners. heterogeneous integration involves the combination of separately fabricated micro-devices (e.g., transistors, leds, sensors) or device components (e.g., interface layer, porous membrane) at the pre-package stage. the  $\mu$ tp system uses an elastomer stamp typically made of polydimethylsiloxane (pdms), which is deformable and surface-compliant, transparent, and adhesive; all characteristics needed to transfer devices with precise alignment. the devices must be singulated and released using an undercut etch of sacrificial material, yet still anchored to the source substrate with one or more tethers at the perimeter. sacrificial release layers are engineered such that tethers will be overcome by the pickup force, which allows device coupons to be removed from their native substrate. the stamp adhesion is pull-rate sensitive, or kinetically modulated, allowing it to remove anchored or tethered devices using a high pull-rate, and release the same device onto a destination substrate using a low pull-rate. the formation of local electrical/optical interconnects between mixed-technology devices in close proximity allows them to interact at an intimate level, realizing microsystems that are otherwise not possible. the investigators propose to utilize the  $\mu$ tp system for the heterogeneous integration of device components in several areas of research. these are listed (with specific applications) as follows: silicon cmos and thin-film electronics (backplane platforms, back-end devices); display devices (iii v and iii n micro-leds); photovoltaics and power conversion (iii v multi junction cells); integrated photonics (lasers, electro-optic materials, modulators); quantum integrated photonics (quantum emitters, single photon detectors, photonic cavities); mixed-dimensional hybrid nanosystems (iii-v devices on 2d monolayers); nanoporous biodevices (electrode transfer, sensor arrays). the  $\mu$ tp system will enable the realization of "monolithic-like" microsystems, with associated advantages in electronic/photonic system performance. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Responsible Engineering across Cultures: Investigating the Effects of Culture and Education on Ethical Reasoning and Dispositions of Engineering Students

Awardee: University of Pittsburgh

Amount: \$198,562.00

Abstract: responsible engineering across cultures: investigating the effects of culture and education on ethical reasoning and dispositions of engineering students      engineering is more cross-cultural and international than ever before, resulting in potential disagreements about (in)appropriate courses of action, which can impede engineering work. despite high rates of international enrollment and an increased focus on global dimensions of engineering in us programs, ethical issues arising from global engineering have been insufficiently addressed. to address these issues, this project will assess the impact of culture and education on ethics among engineering students in north america, europe, and asia. understanding if and how diverse cultural backgrounds and educational experiences affect professional decision-making and collaborations requires empirical investigation, to develop training that addresses the kinds of challenges engineering students, practitioners, programs, and organizations will increasingly encounter in the globalized world. this project will be beneficial for training the next generation of engineers who are competent in working professionally and ethically in the global context and are responsive to the value of **\*\*diversity\*\*** in quality and sustainable engineering work.      the goal of this project is to identify educational interventions with the greatest effects on ethical reasoning and dispositions of engineering students, whether these effects differ among cultural and national groups, and if/how to modify these interventions to respond effectively to cultural and national differences. to do so, researchers from colorado school of mines, university of pittsburgh, delft university of technology, and shanghai jiao tong university will implement mixed-method, quasi-experimental, longitudinal, and cross-sectional research to: (1) determine the effects of culture and foreign language on the ethical perspectives of first-year engineering students; (2) assess the relative effects of culture and education on these perspectives over four years; (3) use engineering ethics assessment tools across cultures and countries to

examine their cross-cultural validity. findings from this project will be essential to develop educational interventions that effectively respond to the globalized environments of contemporary engineering practice. they will also contribute to the development of more inclusive engineering education, by identifying perspectives potentially marginalized in the reigning paradigms. finally, this project has implications for the development of responsible research education at the graduate level: despite the fact graduate student bodies in stem fields have become increasingly international, limited work has focused on developing culturally responsive ethics curricula for graduate students from diverse backgrounds. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: GP-UP: Developing STEM Identity by Engaging URM Undergraduate Students in Research on Air Pollution in Chicago Communities

Awardee: Colorado State University

Amount: \$195,935.00

Abstract: this award is funded in whole or in part under the american rescue plan act of 2021 (public law 117-2). the geoscience learning community will help students from historically excluded communities build their stem identity through authentic research experience, mentoring, and introduction to geosciences careers. students will learn about air pollution, gain experience with instrumentation, practice computer programing and data analysis, and communicate scientific results by participating in real research with prosocial impact. this project addresses three geopath's program goals: (1) increase the number and **\*\*diversity\*\*** of students in geosciences; 2) prepare students for geoscience careers; and 3) contribute to the evidence base for effective student engagement, learning, and retention in stem. the data collected through this project will be of sufficient quality to contribute to community discussions about how best to reduce air pollution and better protect public health, particularly within vulnerable communities. this project seeks to employ several established evidence-based strategies for the success of students from historically

excluded communities. a focus on student success in stem will include authentic collaborative undergraduate research experiences, sustained mentorship, and engagement in research with a direct link to community benefit. by combining authentic prosocial research and mentoring, the pis aim to build a sense of belonging, self-efficacy, and stem identity in two cohorts of students and help with their successful transitions to stem programs related to the earth sciences. this project specifically proposes to create geoscience learning community that engages undergraduate students from historically excluded communities in research to measure and attribute air pollution in two chicago neighborhoods that differ in socioeconomic status, demographics, and proximity to industrial facilities. the pis will recruit a cohort of undergraduate participants at loyola to join a research-intensive learning community each of year 1 and year 2 of the project. student participants will work closely with scientists and the community-based organizations to design and carry out research that addresses community concerns about air pollution. the project's aims are to 1) provide an applied, socially relevant research experience for student participants; 2) understand how particulate pollution in chicago varies over space and time; and 3) provide air quality data for community use. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Amount: \$195,935.00

Abstract: this award is funded in whole or in part under the american rescue plan act of 2021 (public law 117-2). the geoscience learning community will help students from historically excluded communities build their stem identity through authentic research experience, mentoring, and

introduction to geosciences careers. students will learn about air pollution, gain experience with instrumentation, practice computer programming and data analysis, and communicate scientific results by participating in real research with prosocial impact. this project addresses three geopath program goals: (1) increase the number and **diversity** of students in geosciences; 2) prepare students for geoscience careers; and 3) contribute to the evidence base for effective student engagement, learning, and retention in stem. the data collected through this project will be of sufficient quality to contribute to community discussions about how best to reduce air pollution and better protect public health, particularly within vulnerable communities. this project seeks to employ several established evidence-based strategies for the success of students from historically excluded communities. a focus on student success in stem will include authentic collaborative undergraduate research experiences, sustained mentorship, and engagement in research with a direct link to community benefit. by combining authentic prosocial research and mentoring, the project aims to build a sense of belonging, self-efficacy, and stem identity in two cohorts of students and help with their successful transitions to stem programs related to the earth sciences. this project specifically proposes to create geoscience learning community that engages undergraduate students from historically excluded communities in research to measure and attribute air pollution in two chicago neighborhoods that differ in socioeconomic status, demographics, and proximity to industrial facilities. the project will recruit a cohort of undergraduate participants at loyola to join a research-intensive learning community each of year 1 and year 2 of the project. student participants will work closely with scientists and the community-based organizations to design and carry out research that addresses community concerns about air pollution. the project's aims are to 1) provide an applied, socially relevant research experience for student participants; 2) understand how particulate pollution in chicago varies over space and time; and 3) provide air quality data for community use. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: GEOPATHS IN: DIG CAMP - Data in Geosciences: Collaboration and Mentoring Program?Teaming Latinx High School and College Students for Data Use in Geosciences

Awardee: University of California-Santa Cruz

Amount: \$194,760.00

Abstract: this award is funded in whole or in part under the american rescue plan act of 2021 (public law 117-2). atmospheric, climate, ocean, earth and environmental sciences (geosciences) are among the least diverse fields in science, technology, engineering and math (stem), with latinx scientists being significantly underrepresented. a lack of **\*\*diversity\*\*** in stem fields means decreased ability to identify and solve critical issues facing society such as climate change, which disproportionately affects the populations that are least represented in stem. data literacy is gaining increasing relevance and importance to scientists and the general public as we aim to make informed decisions to solve locally and globally relevant problems. dig camp (data in geosciences: collaboration and mentoring program?teaming latinx high school and college students for data use in geosciences) offers a camp-based model to support engagement with geosciences, as well as data literacy. during this project and through its sustainability plan, dig camp provides opportunities for latinx high school students to engage with authentic and locally relevant geosciences research and data; gain geosciences content knowledge; build their data literacy, critical thinking, problem solving, and collaboration skills; strengthen their identities to do science; and increase the likelihood that they will pursue academic or workplace careers in the geosciences. dig camp - data in geosciences: collaboration and mentoring program?teaming latinx high school and college students for data use in geosciences will broaden participation in the geosciences among communities of color by developing a research-based model for overcoming long standing barriers and biases within the field. the goals of this project are to: (1) design and implement a complementary suite of informal

learning experiences to actively recruit latinx high school students into the geosciences by increasing their engagement, capacity building, and opportunities for continuity in the discipline; (2) provide latinx undergraduate geosciences majors with meaningful outreach and mentoring opportunities that engage them with communities, and increase their retention in geosciences fields of study and careers; and, (3) support high school students and their undergraduate mentors to build science and data literacy skills and engage with locally relevant geosciences research data to increase their efficacy and success in college and the geosciences workforce. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: LEAPS-MPS: Predator Competition in Systems with Seasonal Birth

Awardee: Texas Tech University

Amount: \$192,908.00

Abstract: in many ecosystems, seasonal processes are experienced as sudden events, disrupting continuous processes. these disparate processes are closely linked, for example when resource consumption (a continuous behavior) determines reproductive capacity (a seasonal event).

describing the links between these processes is fundamental to long-term descriptions of seasonal ecosystems. this project bridges a gap between common mathematical methods which describe these processes separately, combining them into a hybrid framework. the framework permits long-term models of seasonal ecosystems. long-term models are necessary for ecological forecasts and seasonal behavior is especially relevant for incorporating sensitivities to annual climate. hybrid models are therefore broadly applicable to a range of ecological problems. this project focuses on hybrid descriptions of competition between predatory insects which consume pests in agricultural ecosystems, with attention to how changing temperatures affect pest control. the project also assesses hybrid model performance in arbitrary ecosystems, building broader capacity to address conservation and management problems. the project is hosted at a hispanic serving institution and supports undergraduate research in ecological modelling, which is an accessible entry point to mathematical research and fosters computational skills applicable to a multitude of technical careers. participation includes travel to a scientific conference for postgraduate planning and community building among groups underrepresented in mathematics, where the pi will also seek applicants for supported graduate student research. the project improves institutional capacity to support students from groups underrepresented in mathematics through the development of tailored resources for retention and job placement, which also amplifies existing initiatives broadening participation in mathematics.

describing the interface between long-term (discrete) and short-term (continuous) changes to an ecological population requires mathematical models which couple continuous differential equations and discrete difference equations. this coupling results in a hybrid model, which incorporates population processes over disparate timescales and describes seasonal ecosystems? long-term development. however, dynamics of such models are difficult to assess if the continuous equations incorporate complex behaviors, as is necessary for the target model of predator-prey interactions in a community of generalist predators. this project investigates the effects of competition and seasonal birth on long-term prey abundance and predator coexistence in hybrid models in three stages: (1) through the analysis of simple, two-predator models to build

intuition for the interplay between predator competition and seasonal birth; (2) by extending the hybrid model to investigate the effects of predator **diversity** and temperature variability on pest control in a real agricultural ecosystem; and (3) through the numerical simulation of many complex, theoretical ecosystems to compare persistence outcomes between hybrid and continuous models. preliminary theoretical analysis of fixed points and other stable outcomes yields a thorough understanding of how specific behaviors influence population trajectories, facilitating later work. parameterizing the hybrid competition model from prior abundance data and empirical observations provides insight into the effects of similar behaviors in real agricultural ecosystems. simulating hybrid models for a range of parameters and feeding interactions establishes the conditions under which species persistence is affected by seasonal behaviors. together, the three stages establish a foundational understanding of hybrid models in seasonal ecosystems. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: ERI: Investigation of the Effect of Venous Valve Morphology on Fluid Flow Conditions and Disease

Awardee: Utah Valley University

Amount: \$192,521.00

Abstract: this award is funded in whole or in part under the american rescue plan act of 2021 (public law 117-2). this engineering research initiation (eri) award will support fundamental research that will build understanding of the impact of venous valve properties on the development of disease. therefore, this work will promote the progress of science and advance the national health, prosperity and welfare. the body pumps blood using a combination of venous valves and muscle contractions. together, the valves and muscles pump blood against gravity to get from locations such as the legs back to the heart. deep vein thrombosis occurs when blood cells build up in the veins near venous valves to form blood clots known as thrombi. thrombi prevent the valves from functioning properly, and can lead to pulmonary embolism, which is a leading cause of death in the united states and other industrialized countries. it is known that fluid flow conditions in the veins influence when and where a thrombus forms. however, the effect of various properties of venous valves on flow conditions and thrombus formation is mostly unknown. this work will use both computer simulations

and experimental testing to identify the most important venous valve properties. then, this work will determine how these properties affect flow conditions and lead to thrombus formation. this work will reveal how and where venous valves contribute to thrombosis. these results will ultimately improve assessments of thrombosis risk. additionally, this research will advance engineering education and **\*\*diversity\*\***. community outreach activities will include the use of venous valve models in local schools in underserved neighborhoods. this project will also provide opportunity for undergraduate students, including those from underrepresented groups, to learn the research process. fluid dynamic factors such as shear stress, fluid stasis, and fluid residence time are thought to generally be critical to thrombus formation. in this supported work, a combined approach consisting of both fluid-solid interaction modeling and simulation, and experimental model valve flow imaging and characterization will be employed. these two approaches will complement and support each other in elucidating the effect of valve morphology on the aforementioned disease-conducive flow conditions. the work here will not only help give understanding of the effects and behavior of physiological valves, but will also lead to more effective design of prosthetic valves to avoid problems seen in certain physiological morphologies. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: CAREER: Integrating river hydrology across scales: advancing understanding of the global river-atmosphere interface

Awardee: Texas A&M University

Amount: \$191,952.00

Abstract: rivers are natural hotspots for greenhouse gas emissions and are included in global carbon budget evaluations. however, the amount of greenhouse gas emitted by rivers is highly uncertain largely due to a fundamental gap in the current understanding of hydraulic scaling between small

streams and large rivers. this project will develop a predictive understanding of how geomorphic and hydrologic processes combine to drive river-atmosphere interface dynamics across spatial and temporal scales. it will test underlying assumptions involved in estimating the global surface area of earth's rivers and streams and it will be used to more accurately estimate the global rates of greenhouse gas emissions from inland waters. the integrated research and teaching program will promote hydrologic and environmental literacy and awareness through public outreach and education, and it will help recruit and retain underrepresented minority students with the goal of increasing participation and **diversity** in stem. this research will quantify the full size-distribution of river surface area within a continental-scale river basin by combining satellite, airborne, and fieldwork observations. using these observations, this work will assess the interactions between river surfaces and streamflow at different time and spatial scales and develop a novel open-source model for predicting the river-atmosphere interface dynamics based on hydrologic drivers. the knowledge generated from this project will help fill in the conceptual gaps in our understanding of the river-atmosphere interface and develop the next generation of global river surface area products used in carbon budgets. this research will also untangle the hydrologic and geomorphic drivers of changing river morphology, advancing our understanding of how humans are impacting river systems and aquatic ecosystems. this award is co-funded by the hydrologic sciences and geomorphology & land-use dynamics programs. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: ERI: A Novel Solution to Enable High-Voltage DC-Links in Electric Vehicles

Awardee: SUNY College at Oswego

Amount: \$187,599.00

Abstract: this award is funded in whole or in part under the american rescue plan act of 2021 (public law 117-2). the history of electric vehicles can be traced back to the 19th century. after the initial rise, electric vehicles declined with the mass production of cheaper gasoline cars. until the last century, electric vehicles came back into sight due to fossil fuel shortage and environmental concerns. besides reducing fossil fuel consumption and environmental benefits, electric vehicles offer numerous other benefits such as increasing fuel **\*\*diversity\*\***, providing opportunities to integrate more renewable energy into the grid, and offering individual benefits including better driving experience and less expensive and frequent maintenance, etc. today, the wider adoption of electric vehicles will rely on future technological advances to further reduce the cost and charging time of electric vehicles and increase efficiency, power density, and performance at the same time. one of such technologies is to use high-voltage dc links in electric vehicles. it has been reported that using higher dc voltage in electric vehicles gives higher power density, less weight, smaller components, less loss and heat, and faster charging, etc. thus, using a high dc link voltage has become a new design trend in the electric vehicle industry. the proposed project will focus on the power conversion solutions in electric vehicles to address the challenges encountered in this transition from low-voltage dc links to high-voltage dc links. it will advance the power conversion technology for electric vehicles and other similar power conversion systems, which eventually will improve the united state's competitiveness in the global electric vehicle market, reduce fossil fuel consumption and co2 emissions by promoting the adoption of electric vehicles, and increase energy **\*\*diversity\*\*** and foster national security and energy independence. the education components in the project will enhance engineering education and produce a highly skilled and qualified engineering workforce, attract more students in stem learning as the future workforce in the high-need areas, and help improve the competencies of future stem teachers. the project will also broaden the

participation of underrepresented groups, particularly, first-generation college students and children in poverty. the goal of the project is to develop a cost-effective, highly efficient, and easy-retrofit inverter technique to facilitate the faster development and adoption of high-voltage dc links in electric vehicles. more specifically, the goal will be achieved by 1) developing less costly traction inverter solutions for electric vehicles with a high-voltage dc link by using four-switch three-phase inverter topology, 2) investigating and optimizing the control and efficiency of the inverters using simulations, 3) developing prototypes of the proposed inverters and demonstrating their performance as a comparison to traditional solutions to validate the proposed method, and 4) exploring the applications of silicon carbide devices in the proposed inverters for further efficiency improvement and conducting comparative studies in these methods. the project will advance the knowledge of the proposed inverters and providing mathematical insights on their analysis and control. it will also provide a novel, original, and potentially transformative solution to enable high voltage dc-links in electric vehicles, which can facilitate the faster development of high-voltage dc-link designs. the technology that will be developed in the project can also benefit many other systems such as solar and wind generation, energy storage, utilities, and industrial drive, etc. by providing a low-cost alternative. besides, it provides the possibility to overcome the cost barrier of wide-bandgap devices and promote their applications for better efficiency and more energy savings.

this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: ERI: Towards Data-Capable Engineers with a Variability-Capable Mindset

Awardee: Franklin W. Olin College of Engineering

Amount: \$186,861.00

Abstract: this award is funded in whole or in part under the american rescue plan act of 2021 (public law 117-2) engineers are responsible for delivering safe, efficient solutions. for instance,

automobile manufacturers need to design cars that are light enough to be gas-efficient, but still sturdy enough to protect the passenger. a complication in this design process is variability: no engineer can predict with 100% confidence what a driver will do with their car or what conditions it will encounter. traditionally, engineers handle variability by "overdesign"---making things heavier than they need to be. however, scientists from other disciplines (such as statisticians) have more efficient ways to handle variability. a better understanding of variability---and how engineers themselves react to it---will lead to safer, more efficient engineering designs. achieving these efficiency gains is critical for american economic competitiveness and for addressing anthropogenic climate change. funded by the nsf's research in the formation of engineers initiative, this project will study how real engineers react to variability and will train them to handle it more efficiently.

variability is a key challenge in data analysis: in order to realize the nsf's big idea of harnessing the data revolution, engineers will need to have a variability-capable mindset. however, present engineering education results in professionals who struggle to recognize and manage variability in engineering applications. this lack of engineering workforce capability leads to inefficient designs, and in some cases, dangerously unreliable systems. the aim of this research is to study and improve the formation of engineers' variability-capability. the challenges of variability are well-documented: people generally have difficulty reasoning about variability in climate science, election forecasting, and matters of human judgment. this lack of variability-capability leads to climate inaction, political disengagement, and an unacceptably capricious application of justice. focused on engineering, the primary investigator's previous work identified decades-standing safety issues in aircraft design, stemming from a misidentification of a source of deviation (design-relevant variability) as noise (induced measurement variability). this project will be a mixed-methods study of practicing engineers: to investigate their ability to identify and treat different sources of variability, to develop a quantitative instrument to characterize present engineering workforce capabilities, and to design and deploy teaching interventions to improve engineers' variability-capability. data collection will be paired with professional development workshops, which will synergistically create broader impacts

via direct training. the project will advance our collective understanding and treatment of statistical variation, grounded in engineering practice. the mixed-methods study will fill gaps in the literature on how practicing engineers reason about variability. working closely with engineers in professional development workshops will surface a library of real-world examples of noise and deviation, strengthening the novel theoretical framework with a **diversity** of practical examples. sampling practitioners from across disciplines will also provide novel understanding of the differences across engineering fields, comparing current statistical practices in engineering and attributing them to differences in training and paradigm. the proposed work will develop and deploy teaching interventions to train data- and variability-capable engineers through professional development workshops. thus broader impact will be realized both directly (through the professional development workshops) and indirectly (through dissemination of the teaching interventions to other institutions).

this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Integrative ecological perspectives on extinction processes - a multi-proxy case study of Hispaniolan subfossil and extant rodents

Awardee: University of Cincinnati Main Campus

Amount: \$185,556.00

Abstract: this project brings together researchers and educators specializing in genetics, anatomy, and ecology to explore the factors that led to the recent extinction of endemic rodents on hispaniola. hispaniolan rodents provide an exceptional case study for examining the triggers and timeline of island extinction events. bio**diversity** loss is a global concern, and over 70% of mammalian extinctions in the last 500 years have occurred on islands. the caribbean has suffered the greatest species loss of any region in the world. fossil data generated from this project have the potential to contribute to conservation policy by clarifying which factors most contributed to extinction events,

and will be helpful for understanding the disappearance of species on other islands. this project will contribute to education by providing mentorship to young scientists at multiple levels, including caribbean and caribbean-american undergraduates and by developing teaching modules for k-12 students. finally, a database of extinct hispaniolan mammals will provide better public access to scientific information both in haiti and the usa. this project will use morphometrics, stable isotope ecology, and ancient dna to (1) identify the ecological relationships among hispaniola's extinct endemic rodents, (2) determine the timing of species loss, (3) resolve phylogenetic relationships among extinct taxa, and (4) clarify extinction triggers. the research team will rely on previously collected fossil material from three paleontologically-rich caves on the tiburon peninsula in southwestern haiti. the data generated will allow a more nuanced understanding of the roles that human behavior, climate, and individual species characteristics (e.g., body size, habitat, genetic **diversity**) have played in extinctions on hispaniola. the data generated can be leveraged by conservation biologists to inform conservation policy aimed at preserving the remaining biological **diversity** on hispaniola and in island systems more generally. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: SBP: CAREER: Race, Gender, and the Science of Science

Awardee: University of Notre Dame

Amount: \$184,412.00

Abstract: the "science of science" has recently exploded in popularity as researchers turn scientific methods of investigation around to investigate the practice of science itself. while some attention has been paid to issues of marginalization and representation, these concerns have generally not been brought to bear on other questions within the science of science regarding how to enhance scientific progress. the research component of this project fills the resulting gaps in our

understanding. the project demonstrates when attempts to improve science not only further entrench (or even amplify) current injustices, but backfire, ultimately impeding scientific progress. moreover, it examines how ideas spread throughout diverse communities, both providing insight into how current inequities hinder scientific progress and illuminating questions surrounding belief spread and polarization. finally, it uncovers hidden, unsuspected roadblocks for marginalized groups and suggests potential remedies, promoting **\*\*diversity\*\*** in scientific fields. this research component is intertwined with teaching and outreach components, with initiatives including the development of courses discussing diverse methods used to investigate scientific practice (e.g., from philosophy, history, sociology, science of science), a national workshop for members of underrepresented/marginalized groups intending to pursue research in the science of science, and innovative k-12 stem programming which demonstrates the importance of **\*\*diversity\*\*** in action.

this project employs tools from evolutionary game theory and network science to provide a picture of how aspects of social identity, e.g. race and gender, matter both to scientific progress and to how researchers scientifically investigate the institution of science. these tools, which capture the dynamics of scientists' interactions and the structure of scientific communities, enable the project to integrate insights from feminist philosophy of science with insights from science of science, to the benefit of both fields. many theories in the science of science take for granted that there are the same credit incentives, chances of work being published and cited, etc. for all scientists, regardless of social identity. yet, as has long been recognized within feminist philosophy of science, these considerations matter: researchers are excluded or marginalized according to social identity, and scientific progress is hampered by the resulting lack of diverse ideas and perspectives. this project reveals how our understanding of how to achieve well-functioning science can change drastically once social identity is taken into account. meanwhile, the scientific tools used in this project have clear power to illuminate questions of interest to feminist philosophers of science, e.g. how communication networks within scientific communities influence knowledge generation. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the

foundation's intellectual merit and broader impacts review criteria.

Title: GCR: Collaborative Research: Designing a Sustainable Agricultural Production System through Convergence Research Using a Multi-Scale Ecosystems Approach

Awardee: Indiana University of Pennsylvania Research Institute

Amount: \$181,090.00

Abstract: this project addresses the grand challenge of sustainability of food systems, a complex issue that requires deep integration of scientific and engineering disciplines as well as participation by all stakeholders. this project brings together conservation biologists, ecologists, agronomists, farmers, indigenous peoples, economists, social scientists, land managers, and engineers to co-design and implement a framework for testing approaches to sustainable agricultural production. the research team will use this to study the impact in a model system, coffee production, of integrating technological innovations, such as us-built, industrial renewable-energy dryers and clean wet mills that recycle coffee pulp and reduce water pollution, with environmentally-friendly economic development where farmers are compensated for preserving forest on their lands through carbon offset credits, and community-led training and outreach and microcredit programs intended to increase both the participation of women and production. such a system has the potential to conserve forest critical to reducing carbon emissions, support bio\*\*diversity\*\*, including migratory birds, and enhance the stability of economic and social conditions. the goal of the project is to develop a framework for convergence research targeting the development of sustainable food systems using the tools of socio-ecological systems, extended to a multiscale ecosystem framework. the research team will construct a multi-scale empirical socio-ecological model of the food production system, identifying the structural elements at all relevant scales, the inter- and intra-scale interactions among those elements, and ecosystem and social services at multiple scales. this model will allow quantification of sustainability metrics under different scenarios. it will

be used to identify tradeoffs, synergies and critical points among sustainability indicators and to perform scenario analyses of the impacts of critical exogenous drivers, including market fluctuations and climate change, on the elements of the system. this project is jointly funded by the growing convergence research program and the established program to stimulate competitive research (epscor). this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: How many routes to the same phenotype? Genetic changes underlying parallel acquisition of mimetic color patterns across bumble bees

Awardee: University of Alabama Tuscaloosa

Amount: \$179,228.00

Abstract: hundreds of bumble bee species are important pollinators worldwide. they also have interesting behaviors and morphologies that tell us about evolution. color pattern **\*\*diversity\*\*** is the most notable of these traits. these species have hundreds of different patterns of yellow, orange, black, and white hairs across their bodies. this **\*\*diversity\*\*** is related to mimicry, whereby species converge upon the same pattern to avoid predation. however, that dominant color pattern differs by region. this repeated evolution of color patterns can be used to understand how genes are targeted during evolution. in the western united states, several bumble bee species undergo parallel changes across the landscape. this research will examine the genes that drive coloration shifts in each of these western species and provide a better understanding of how repeatable evolution is. broader impacts of the research include training undergraduate students to develop functional genetics tools. the researchers will also share their gained knowledge outside the scientific community through several events for the public and develop color pattern field guides for bumble bees. the study will compare genes across repeated color shifts to tell if the same genes are repeatedly targeted or if

there are many ways to get to the same phenotype. the proposed research uses a combination of genome-wide trait association analysis and cross-developmental transcriptome comparisons to determine gene networks for color variation across five sets of mimetic species in the western united states. this includes identifying genetic targets specific changes in final pigmentation genes. it will tell which regions within genes are most likely to be targeted. it will determine if there are major developmental genes that get used in new functions or if downstream genes are more often targeted. it will also tell us how genetic variants inherited and transferred within and across species influence total **\*\*diversity\*\***. this study will provide genome sequences for several north american bumble bees, clarifying species boundaries hidden by mimicry. it will also improve understanding of the role of developmental and pigmentation genes in animals. genomes will be sequenced for species across a clade of mimics to reveal how color-determining genes evolve. these objectives will provide a case study of how genetic variants and resulting changes in gene expression evolve across species under selection. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Abstract: hundreds of bumble bee species are important pollinators worldwide. they also have interesting behaviors and morphologies that tell us about evolution. color pattern **\*\*diversity\*\*** is the most notable of these traits. these species have hundreds of different patterns of yellow, orange, black, and white hairs across their bodies. this **\*\*diversity\*\*** is related to mimicry, whereby species converge upon the same pattern to avoid predation. however, that dominant color pattern differs by

region. this repeated evolution of color patterns can be used to understand how genes are targeted during evolution. in the western united states, several bumble bee species undergo parallel changes across the landscape. this research will examine the genes that drive coloration shifts in each of these western species and provide a better understanding of how repeatable evolution is. broader impacts of the research include training undergraduate students to develop functional genetics tools. the researchers will also share their gained knowledge outside the scientific community through several events for the public and develop color pattern field guides for bumble bees. the study will compare genes across repeated color shifts to tell if the same genes are repeatedly targeted or if there are many ways to get to the same phenotype. the proposed research uses a combination of genome-wide trait association analysis and cross-developmental transcriptome comparisons to determine gene networks for color variation across five sets of mimetic species in the western united states. this includes identifying genetic targets specific changes in final pigmentation genes. it will tell which regions within genes are most likely to be targeted. it will determine if there are major developmental genes that get used in new functions or if downstream genes are more often targeted. it will also tell us how genetic variants inherited and transferred within and across species influence total **\*\*diversity\*\***. this study will provide genome sequences for several north american bumble bees, clarifying species boundaries hidden by mimicry. it will also improve understanding of the role of developmental and pigmentation genes in animals. genomes will be sequenced for species across a clade of mimics to reveal how color-determining genes evolve. these objectives will provide a case study of how genetic variants and resulting changes in gene expression evolve across species under selection. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Does responding to stressors prime greater resilience? Testing the

long-term effects of challenges on behavior, physiology, epigenetic state, and fitness.

Awardee: Franklin and Marshall College

Amount: \$178,935.00

Abstract: when faced with a major challenge ? severe weather, the attack of a predator, an injury ? organisms mount a coordinated physiological and behavioral stress response. this response can be vital for surviving and recovering from immediate threats. this project will test whether activating the stress response system has another overlooked benefit that operates over much longer time-scales: priming the system to respond better to future challenges. coordinated experiments will address fundamental questions about when and how environmental challenges prime greater resilience to future challenges, and examine whether those effects persist across generations. this study will also adapt and refine newly developed sensor technology that enables non-invasive monitoring of heart rate in free-living animals ? a tool that could yield considerable advances across fields. a more comprehensive understanding of the lingering impacts of challenges will also be valuable for other fields, including conservation and human health. additionally, the team will lead a career development program that combines a field research internship ? in which students participate in addressing the research objectives outlined in this proposal ? with a laboratory- and classroom-based skills development program for students from underrepresented groups who are interested in careers in stem fields. this opportunity is designed to foster interactions among students from a small liberal arts college and from a large research-intensive university. this project will test the hypothesis that transient challenges experienced in adulthood prime greater resilience or robustness to future challenges, defined as the ability to return to or maintain a stable state. research will use a long-term study population of tree swallows (*tachycineta bicolor*) in which large-scale behavioral and physiological data can be collected from free-living individuals. in the first year of study adult females will be exposed to either an ecologically relevant challenge or a simulated glucocorticoid stress response. in the following year(s) a **\*\*diversity\*\*** of phenotypic traits, and context-dependent performance and fitness, will be measured. this study design will enable

comparison of the direct effects of exposure to a challenge with the effects of exposure to a mediator of the response to that challenge. these experiments will also reveal whether the long-term effects of stressors on behavior, physiology, and fitness are mediated by glucocorticoids and by glucocorticoid-induced changes in dna methylation. this research will also test whether parental exposure history carries over to affect the phenotype and fitness of offspring produced in the year(s) after the challenge. by combining targeted experiments in a free-living population with integrative methods of behavioral, physiological, and epigenetic assessment this project will provide insights important for developing and revising conceptual models of stress and phenotypic plasticity. it will also broaden our understanding of the mechanisms of behavior, how organisms are shaped by their environments, and how sub-organismal responses contribute to organismal resilience and robustness. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Low-cost Manufacturing of Bioinspired Damage-Tolerant Ceramic Composites

Awardee: Arizona State University

Amount: \$177,675.00

Abstract: despite favorable properties of ceramic-metal composites, they have not been applied commercially to date, due in large part to processing cost and challenges. the conventional method for manufacturing lamellar ceramic-metal composites is melt-infiltration of the metal phase into the gaps of the ceramic scaffold. the smaller the gap, the more difficult the infiltration. because of the poor wetting between most metals and ceramics, the process requires high pressure and temperature to squeeze the molten metal into the gaps in the ceramic phase. this project aims at developing manufacturing strategies inspired by nature to enable low-cost fabrication of ceramic-metal composites. natural materials such as bone and the nacreous part of sea-shells have developed structural composites, using a set of rather ordinary constituents, which exhibit

extraordinary mechanical properties. for example, seashells convert a brittle ceramic material to a super-tough material (nacre) by incorporation of around 5% polymer, in a layered "brick-and-mortar" microstructure. the scientific community has been very successful in identifying the design principles of biological structural composites. however, manufacturing knowledge gaps persist. these include the challenge of infiltration of small gaps between ceramic bricks, the challenge of obtaining ductile (while strong) mortars; the challenge in design of proper (metal-ceramic) interfaces; and the high cost. low-cost processes for fabrication of metal&#8722;ceramic composites can substantially increase their applications in various industries including automotive, aerospace, oil and defense, in products such as high performance wear-resistance parts, cutting tools, lightweight structural composites, and aero-engine components. for these reasons, the project directly impacts american economic welfare and national security. the educational objective of the project is focused on increasing the **\*\*diversity\*\*** in nanotechnology-stem through "nanoexplorer" summer program for high school students, with particular emphasis on female students, including latinos. the goal of this research is to investigate the mechanisms underlying processing and manufacturing of ceramic composites for damage-tolerant structural applications. the project is focused on understanding infiltration of nanotwinned metals into nano-gaps (<100 nm) of a 3-dimensional porous ceramic scaffold by pulsed electrodeposition. a conservative estimate shows that the energy consumption in this process is more than 200-fold smaller than the conventional molten metal infiltration process. the liquid electrolyte in electrodeposition has much less viscosity compared to molten metals, and hence can effectively penetrate into the small gaps between the ceramic bricks. a class of metals that defeat the trade-off between strength and toughness are "nanotwinned" metals. nanotwinned metals have high density of coherent twin boundaries, which has been shown to enhance both strength and ductility. pulsed electrodeposition is one of the primary methods of synthesis of nanotwinned metals. to address the metal-ceramic interface challenge, electroless deposition of a thin metal layer on ceramic bricks is planned, which will result in uniform coating, as well as strong adhesion between ceramics and

metals. this research, if successful, will result in new fundamental knowledge in following subjects:

(i) growth mechanism and microstructure of nanotwinned metals directly synthesized by pulsed electrodeposition into a laminated ceramic scaffold; (ii) kinetics of pulsed electrodeposition process in nano-channels (<100 nm); and (iii) infiltration of a nano-porous ceramic scaffold by electrodeposition. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Digitization TCN: Extending Anthophila research through image and trait digitization (Big-Bee)

Awardee: Harvard University

Amount: \$177,103.00

Abstract: declining populations of bees impact plant-pollinator interactions in both natural and agricultural systems. while bees and other insects pollinate most wild plants, and are critical to sustain a large proportion of global food production, they are decreasing in both numbers and **\*\*diversity\*\***. our understanding of the factors driving these declines is limited because we lack sufficient data on the distribution of bee species, and on the behavioral and anatomical traits that may make them either vulnerable or resilient to human-induced environmental changes, such as habitat loss and climate change. fortunately, wild bees have been collected by researchers and deposited in natural history collections for over 100 years, retaining a wealth of associated attributes that can be extracted from specimen images. this project will digitally capture data and images from these historic specimens, develop tools to measure bee traits from these images, and generate a comprehensive bee trait and image dataset to measure changes through time. this will increase our understanding of specific traits that put bee species at risk of decline - a critical need for both sustaining our agricultural economy and the conservation of our natural resources. in addition, the

large image datasets created by this project can be used for new artificial intelligence identification tools that will help improve our future pollinator observation and monitoring efforts. the big-bee thematic collection network (big-bee tcn) will create over one million high-resolution 2d and 3d images of bee specimens, representing over 5,000 worldwide bee species, including all of the major pollinating species of the united states. the big-bee network includes 13 institutions and partnerships with us government agencies. novel mechanisms for sharing image datasets will be developed and datasets of bee traits will be available through an open data portal, the bee library, for research and education. the big-bee project will engage the general public in research through community science via crowdsourcing trait measurements and data transcription from images. in addition, training and professional development for natural history collection staff, researchers, and university students in data science will be provided through the creation and implementation of workshops focusing on bee traits and species identification. all data resulting from this award will be shared with and publicly available through the national digitized biocollections resource, [idigbio.org](http://idigbio.org). this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: GRate ? Integrating data and modeling to quantify rates of Greenland Ice Sheet change, Holocene to future

Awardee: Dartmouth College

Amount: \$175,229.00

Abstract: the greenland ice sheet has experienced devastating melt in recent years. recent scientific reports highlight how vulnerable the greenland ice sheet is to arctic climate change and draw a dire picture of the impact of sea-level rise. in order to equip society with the best forecasts of sea level rise for planning, scientists need to improve the ability to simulate ? or model ? the response of ice sheets to climate change. for this project, scientists from different branches of ice-sheet research will

work together to improve ice sheet modelling. the researchers will leverage recent scientific advances to model the entire greenland ice sheet in order to investigate long-term ice-sheet sensitivity to changes taking places in the ocean and atmosphere. the research group is committed to creating an inclusive environment where all team members can learn and excel. the team contains **\*\*diversity\*\*** in ethnicity, gender and rank, and will train six early career scholars, recruiting specifically from groups underrepresented in the geosciences, which is among the least diverse stem fields in the u.s. results will be made publicly available and will facilitate a broad range of future research about the arctic system, including ice sheet modeling, model spin-up, paleoclimate reconstruction/synthesis and glacier history. to elevate the capacity of outreach and education programs developed during their first project, the team will build on their ?scientists are superheroes? outreach program and leverage other, existing outreach frameworks, including making connections with greenlandic communities and with high school student intern programs at their universities linked to the young women?s leadership school (bronx, ny) and the spring valley (ny) branch of the naacp, coordinated by our dedicated project educator and outreach specialist.

reducing uncertainties in ice-sheet model predictions is crucial in society?s handling of the sea level crisis. uncertainties related to ice-sheet instability arise from limited observations, inadequate model representation of ice-sheet processes, and limited understanding of the complex interactions between the atmosphere, ocean, and ice sheets. how atmospheric and oceanic forcing vary through time, and at what timescales each are capable of forcing rapid change, are critical for predicting future ice mass loss, but scientists have been observing ice sheet change for only a short period of time (decades). the pis propose to scrutinize greenland ice sheet change spanning from the beginning of the holocene (12,000 years ago) to 2100 ce, making it possible to evaluate the varying roles of atmospheric and ocean forcing on decadal-to-centennial timescales relevant for the future greenland ice sheet evolution. the pis will utilize their established multi-disciplinary collaboration to combine ice sheet modelling, climate forcing and reconstructions of past ice-sheet change. this will position the team to make predictions of future ice sheet change that are grounded in greenland ice

sheet behavior during past climate swings that occurred prior to our brief window of modern observation. the work will lead to lasting products to serve the community's collective effort to better understand ice sheet change: 1) a state-of-the-art ice-sheet model optimized for simulations over long timescales, 2) a holocene-through-modern set of atmospheric and ocean state estimates optimized for forcing an ice-sheet model, and 3) a database of past-ice sheet configurations and paleoclimate records formatted for model-data comparison. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Digitization PEN: BatPEN! A Partnership to Facilitate Scientific Inquiry into the Vast Functional Trait Diversity of Phyllostomid Bats

Awardee: Texas Tech University

Amount: \$175,000.00

Abstract: through the process of diversification, more organisms exist today than at any other time during the history of life. however, this bio\*\*diversity\*\* is not evenly distributed through space, time, or across the tree of life. understanding phenotypic trait variability across taxa provides information that is valuable for answering some of the most fundamental questions in biology such as, what determines the relationship between form and function, how do different phenotypes facilitate coexistence across communities, or how has the evolution of phenotypic characteristics influenced the levels of bio\*\*diversity\*\* exhibited today? variation in phenotypic traits forms the bedrock of understanding in much of ecology, evolution, and systematics. in partnership with the overt tcn, the batpen! project will mobilize high-resolution phenotypic functional-trait data from the neotropical bat family phyllostomidae. the aim of batpen! is to increase the abundance of available functional trait data, create scientific infrastructure, and facilitate scientific inquiry into the most diverse family-level clade of mammals. moreover, the project will fuel novel stem training opportunities and enable major research avenues in ecology and evolutionary biology. batpen! will generate about 1000 high-resolution computerized tomography (ct) scans of entire museum specimens to fill in representation of the 214 phyllostomid species with the aim to substantially compliment the one species per genus taxonomic coverage of overt. this will also add additional novel coverage to overt in two ways, first by including deeper intraspecific coverage of 5 taxa that phylogenetically span the higher-level monophyletic subclades of phyllostomidae based on 10 individuals from each of 10 different sites distributed across the neotropics, and second, by scanning ontogenetic series from

three species exhibiting three different degrees of sexual dimorphism. immediate educational and research impacts will occur by adherence to core data management protocols of the overt-tcn, including hosting open phenotypic data on morphosource (morphosource.org) and seamlessly linking these data back to original specimens and other specimen-derived resources via idigbio (idigbio.org). batpen! will facilitate museum-based scientific infrastructure through not just making digitized data streams available but by training the next generation of museum scientists. batpen! will be based at a hispanic serving institution and will ensure direct involvement of under-represented groups in stem. the project will draw undergraduates from texas tech's ethnically diverse population to assist with research related to batpen! through the center for the integration of stem education and research (ciser). in cooperation with the museum science and heritage graduate program at texas tech, museum science students will be trained in curational/collections activities to contribute to the next generation of collection-based researchers and educators. in addition, a formal course will be offered entitled "vertebrate curational techniques," which will provide a hands-on approach to curation and collection activity. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Digitization PEN: Small and Hungry: Enhancing LepNet TCN with microlepidoptera and 50 years of host plant data from the Essig Museum

Awardee: University of California-Berkeley

Amount: \$174,976.00

Abstract: lepidoptera (butterflies and moths) is the most diverse order of insect herbivores. rich in ecological data they are often models for co-evolution, population dynamics, and environmental change. because of their dependence on particular plant species and climate zones, many species are used as environmental indicators of habitat quality and climatic shifts. however, digitization of

insect collections, particularly lepidoptera, lag far behind most other groups due to the large size of collections, the small and delicate nature of specimens, and the tiny, difficult to read specimen labels. the lepidoptera of north america network (lepnet) tcn is addressing this paucity of data by digitizing occurrence records of butterflies and moths from over 28 institutions across the united states, along with high resolution images of over 95,000 species. the essig museum is contributing to this effort by adding over 100 years of specimen records and ecological data from western north america. all data and images are freely and immediately available online through aggregators, including idigbio, gbif, scan, and the essig museum database, to researchers, educators, land managers, conservation planners, and the public. the essig museum is a leading collection of lepidoptera in the western us with extensive taxonomic breadth and occurrence density, particularly for microlepidoptera in northern california and mexico. past and ongoing projects of the essig museum focus on specialized habitats such dunes, coastal scrub, and offshore islands, as well as recovery from wildfires and long-term sampling of regional preserves. moreover, a long tradition of rearing specimens from host plants, including fruit and stem borers, gall-formers, and leaf-miners, has resulted in many decades of detailed records of interaction data including host plants and parasitoids. this project will disseminate georeferenced digital data for 125,000 butterfly and moth specimens, along with high resolution images of 2000 species, including 608 holotypes. these data will fill many gaps for western north america to improve niche modelling efforts and investigate population dynamics for the past 100 years. high resolution images are used to train automated identification services to address bottlenecks in ecological and conservation research and rapid identification of pests. much of the digitization work will be carried out by undergraduate students who will also receive training in bio\*\*diversity\*\* informatics and insect biology. data and analyses derived from this effort will be used in online and public exhibits related to insect evolution, global change biology, and natural history of western north america. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: CRII: CNS: Bringing Predictable Real-time Computing to Connected Autonomous Driving Systems

Awardee: Wayne State University

Amount: \$174,944.00

Abstract: connected vehicle technology is a promising solution to provide reliable autonomous driving that will change the traditional transportation system by building stable, interactive wireless communications between vehicles, the smart infrastructures (e.g., the roadside unit), and personal communications devices. however, achieving reliable and safe connected autonomous driving (cad) is still very challenging. on one hand, the safety of the cad system hinges critically on its timing correctness, as crucial driving decisions fully depend on the output of the real-time perception system. on the other hand, requesting information from other devices mayl create additional delays for the on-vehicle real-time perception tasks, and thus the timing correctness of the cad system can be easily violated by unpredictable communications. this project seeks to bring predictable real-time computing to cad systems, and the goal of the proposed research is to enable the connected autonomous vehicle and exterior devices to perform real-time perception tasks as a whole by (i) establishing a practical real-time task model to integrate exterior devices into the on-vehicle perception system, which can be implemented on the gpu-enabled computing platforms; (ii) proposing real-time task scheduling algorithms and associated timing validation analysis to guarantee that all the real-time perception tasks can complete at the right time; (iii) developing a prototype cad system on the autonomous vehicle testbed, hydraone, and the roadside unit, equinox, to evaluate the real-time performance of the proposed solutions. building a cad system will constitute a major technological breakthrough towards realizing fully autonomous vehicles. in particular, this project emphasizes both scheduling algorithm design and system implementation. the establishment of a real-time suspending-gang task model will enable the first-of-its-kind

formalization for depicting the executing flow of real-time workloads executed between the autonomous vehicle and the exterior devices. the real-time task scheduler oversees the entire system and ensures its timing correctness. the creation of new real-time resource allocation methods together with the associated analysis for validating timing constraints will drive the scheduling theory towards real applications in future cyber-physical systems. the proposed research aims to realize the cad system on the physical platforms (hydraone/equinox), with indoor and outdoor studies beyond simulation. especially, hydraone/equinox are ready-to-use platforms that will allow experts/researchers to easily examine their research designs regarding autonomous driving. educational efforts will be devoted to (i) develop the hydraone educational toolkit for undergraduate education and research, (ii) curriculum design for hands-on learning in the bs/ms program, (iii) summer camp development for k-12 students and teachers, (iv) broadening participation in computing and engineering to enhance **\*\*diversity\*\***. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: CRII: CNS: Auction Mechanism Design for Energy-Efficient High Performance Computing

Awardee: University of South Carolina at Columbia

Amount: \$174,770.00

Abstract: high performance computing (hpc) systems (such as supercomputers) are generally large infrastructures containing thousands of server nodes that can perform computations in a fast and efficient manner. hpc systems can consume an enormous amount of power during their operation. for example, current top-ranked supercomputers can consume tens of megawatts of power during peak operation. as a direct consequence of power consumption increase, energy cost has become a major component of the overall cost of the operation of an hpc system. to achieve energy sustainability in hpc, this project plans to develop novel models to reduce energy cost and contribute to the power system stability. there are three primary objectives of this project: (1) develop machine learning models to predict the power and performance of parallel applications; (2) develop an auction mechanism model to reduce hpc system's energy cost via collective energy reduction of hpc users, while incorporating the renewable energy generation into the model; and (3) experiment and validate the proposed auction mechanism model via simulation. overall, the project is expected to reduce the energy cost of large-scale systems, as well as to achieve power grid energy conservation and stability. this project will contribute towards advancement of the state-of-the-art in energy-efficiency of hpc, as well as to balance the energy-performance trade-offs in hpc. in doing so, this project will increase hpc system's participation in sustainable computing. the proposed research will enable hpc systems to closely interact with the power grid system, and enable feedback-based energy reduction based on electricity price variation and renewable energy generation. this project will increase research participation of both graduate and undergraduate

students. additionally, the project will train and educate students in the area of parallel and high performance computing, and energy-efficient computing. furthermore, through various outreach activities and research involvement, the project plans to promote **\*\*diversity\*\*** in computing by involving underrepresented groups. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: CRII: CNS: A Hybrid Software Defined Networking-Information Centric Networking Framework for the Reuse of Computation at the Network Edge

Awardee: University of Nebraska at Omaha

Amount: \$174,736.00

Abstract: the adoption of next-generation applications, such as augmented reality and internet-of-things (iot), is expected to grow rapidly in the years to come. the number of iot devices is expected to reach 75 billion by 2025, while the scale of potential use-cases (e.g., smart cities with hundreds of thousands or millions of residents) is also expected to grow. in such use-cases, users may request the processing of data with temporal, spatial, or semantic similarity by servers physically close to them. the repeated processing of considerably similar data may result in the same processing outputs and thus the execution of duplicate (redundant) computation. this project advances our understanding of the notion of ?computation reuse?, where the processing outputs are reused/shared among processing requests for similar data, having the potential to: (i) reduce the time for the processing of similar data and thus the overall latency perceived by next-generation applications; and (ii) eliminate the execution of redundant computation, so that the available computing resources are effectively utilized. our project will result in a novel network framework, so that requests for the processing of similar data are identified and forwarded to the same servers, facilitating the reuse of computation in realistic infrastructure deployments. the research outcomes of

this project will be incorporated into university course curriculum, while this project will also offer opportunities that broaden participation and **\*\*diversity\*\*** in stem. this project aims to advance the state-of-the art in edge computing architectures in order to facilitate the reuse of computation through a novel, hybrid network framework based on information-centric networking (icn)/named-data networking (ndn) and software-defined networking (sdn). the proposed framework capitalizes on the best of both icn/ndn and sdn to realize a service-centric, computation reuse-aware, and "softwarized" architecture through: (i) the semantically meaningful icn/ndn naming and stateful forwarding plane for the seamless and adaptive task forwarding towards edge servers that can reuse similar previously executed tasks; and (ii) the separation of forwarding and control planes and the programmable (logically) centralized sdn intelligence for the orchestration of the computation reuse semantics. this project will tackle fundamental challenges in the design and development of network systems for the realization of computation reuse in realistic edge computing environments, where multiple edge servers may be available for redundancy, fault tolerance, and load balancing purposes, facilitating the pervasive edge computing deployment. this project is jointly funded by networking technology and systems(nets)program and the established program to stimulate competitive research (epscor). this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: CRII: CNS: A Hybrid Software Defined Networking-Information Centric Networking Framework for the Reuse of Computation at the Network Edge

Awardee: University of Nebraska at Omaha

Amount: \$174,736.00

Abstract: the adoption of next-generation applications, such as augmented reality and internet-of-things (iot), is expected to grow rapidly in the years to come. the number of iot devices is

expected to reach 75 billion by 2025, while the scale of potential use-cases (e.g., smart cities with hundreds of thousands or millions of residents) is also expected to grow. In such use-cases, users may request the processing of data with temporal, spatial, or semantic similarity by servers physically close to them. The repeated processing of considerably similar data may result in the same processing outputs and thus the execution of duplicate (redundant) computation. This project advances our understanding of the notion of "computation reuse", where the processing outputs are reused/shared among processing requests for similar data, having the potential to: (i) reduce the time for the processing of similar data and thus the overall latency perceived by next-generation applications; and (ii) eliminate the execution of redundant computation, so that the available computing resources are effectively utilized. Our project will result in a novel network framework, so that requests for the processing of similar data are identified and forwarded to the same servers, facilitating the reuse of computation in realistic infrastructure deployments. The research outcomes of this project will be incorporated into university course curriculum, while this project will also offer opportunities that broaden participation and **diversity** in STEM. This project aims to advance the state-of-the-art in edge computing architectures in order to facilitate the reuse of computation through a novel, hybrid network framework based on information-centric networking (ICN)/named-data networking (NDN) and software-defined networking (SDN). The proposed framework capitalizes on the best of both ICN/NDN and SDN to realize a service-centric, computation reuse-aware, and "softwarized" architecture through: (i) the semantically meaningful ICN/NDN naming and stateful forwarding plane for the seamless and adaptive task forwarding towards edge servers that can reuse similar previously executed tasks; and (ii) the separation of forwarding and control planes and the programmable (logically) centralized SDN intelligence for the orchestration of the computation reuse semantics. This project will tackle fundamental challenges in the design and development of network systems for the realization of computation reuse in realistic edge computing environments, where multiple edge servers may be available for redundancy, fault tolerance, and load balancing purposes, facilitating the pervasive edge computing deployment. This project is

jointly funded by networking technology and systems(nets)program and the established program to stimulate competitive research (epscor). this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Digitization PEN: Adding a world-class flea collection to the Terrestrial Parasite Tracker network

Awardee: Carnegie Institute

Amount: \$174,570.00

Abstract: parasitic insects have a global impact on human health, livestock production, and wildlife conservation. building robust datasets of parasites? host preferences, seasonal activity, and geographic range can help scientists and public health professionals understand and predict patterns of disease transmission; however, much of the data needed for these assessments is accessible only through museum collections. the primary goal of this project is to extract this data from a world-class collection of fleas and associated parasites at the carnegie museum of natural history (cmnh). as part of the terrestrial parasite tracker thematic collections network (tpt tcn), high-quality specimen images and host/locality data will be captured, digitized, and shared via public data portals. this will allow entomologists, epidemiologists, and other researchers to make essential connections between disease vectors and their host species. in turn, understanding these connections will support future assessments of economic and health risks from insect-vectored disease. the robert traub flea collection at cmnh is one of the largest and most meticulously curated collections of mammal parasites in the world, with 74,897 specimens mounted under glass on 60,596 glass slides with 4,615 associated genitalic dissections. this project will use automated slide scanning technology developed for pathology laboratory use to capture whole-slide and specimen images efficiently. these images will then be linked with digitized host and locality data

from both slide labels and traub's fieldwork logs. this project will more than quintuple the siphonaptera specimen records for the terrestrial parasite tracker tcn and complete its representation of flea families. this will represent a valuable dataset and image resource not just for tpt tcn and epidemiology research, but for systematic research on siphonaptera in general. disseminating this data through the online data portals, including idigbio.org, symbiota collection of arthropods network (scan), and the global bio\*\*diversity\*\* information facility (gbif). broad digital access will enable researchers and diagnosticians worldwide to access an enormous database of host-parasite relationships as well as to compare their specimens to high-quality specimen images with reliable species-level identifications. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: ER-PF: Using Distributed Acoustic Sensing for Tremor Detection and Site Characterization in Cascadia to Evaluate Earthquake Hazard

Awardee: Mendoza, Manuel Matthew

Amount: \$174,000.00

Abstract: this award is funded in whole or in part under the american rescue plan act of 2021 (public law 117-2). dr. manuel mendoza has been granted an ear postdoctoral fellowship to carry out research and education plans at university of colorado boulder and colorado school of mines. dr. mendoza plans to develop a new technique for earthquake monitoring called distributed acoustic sensing (das). das uses dark (unlit/unused) existing telecommunication fiber optic cables and turns them into an instrument that acts as a network capable of detecting tiny or distant seismic (earthquake) events. in the pacific northwest of the us where two tectonic plates converge, the conditions are right for large earthquakes which could result in other hazards such as tsunamis. therefore, large-scale and continuous seismic monitoring is needed to evaluate the impending risks.

in this project, dr. mendoza will work alongside professors anne sheehan and dr. ge jin to test and demonstrate das performance capabilities by carrying out a das experiment in northwestern washington. specifically, the work will investigate seismic events known as "tremor" and determine how local geologic conditions vary along the fiber cable. dr. mendoza's work will advance understanding of earthquakes, how the ground shakes in response to them, and consequent seismic hazards. the proposed study will provide opportunities for das to be applied at larger scales alongside existing seismic networks to perform multi and interdisciplinary research and monitoring of earth processes. the project will also allow dr. mendoza to teach and mentor students from underrepresented groups, including as a mentor on the \*\*diversity\*\*, inclusion, and access committee at the colorado school of mines and as a summer internship mentor at university of colorado boulder. other activities associated with this project include designing and leading a local das experiment for a geophysics course and supervising the professional and educational development of an undergraduate student who will conduct original research with the das data. at both campuses, the pi will engage in outreach activities aimed at increasing public scientific literacy and broadening participation in the s.t.e.m fields.

distributed acoustic sensing (das) using fiber-optics to measure deformation (strain) caused by seismic perturbations in the earth has, in recent years, proved to be a highly applicable and promising tool in seismology. this is owed to its ability to be configured as a seismic array with an aperture on the order of tens of kilometers, meter-level sensor (i.e. channel) spacing, and performance comparable to that of conventional broadband seismometers. this implies that das arrays can blanket a large area while not suffering from spatial aliasing when sampling the seismic wavefield ? unlike traditional networks ? and provide new information in high fidelity that often goes missed. a single das experiment can therefore be used to simultaneously investigate a variety of earth processes occurring across different spatial and temporal scales. here, the investigators will conduct the first known das experiment in cascadia using fiber from an existing telecommunication cable, to monitor tremor and characterize site conditions for the purpose of evaluating seismic hazard. specifically, the pi will

pursue three primary scientific goals: (1) use das to detect and locate tremor in cascadia; (2) characterize its spatiotemporal behavior and infer its contribution to stressing the up-dip locked portion of the plate interface; and (3) determine meter-level variation in site conditions along the das array. these goals will be addressed by employing seismic array-based techniques such as beamforming and beam back-projection to capture tremor, as well as ambient noise interferometry techniques to estimate shear wave velocities of the top 30 meters (vs30). the results obtained from this study will be compared to other observations performed using different instruments and methods, to demonstrate the efficacy of das in improving earthquake and ground shaking models in cascadia and assess its implications for future experiments in a variety of tectonic settings. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: EAR-PF: Evolution of landscapes buried by Quaternary sediments

Awardee: Kwang, Jeffrey S

Amount: \$174,000.00

Abstract: dr. jeffrey kwang has been awarded an nsf ear postdoctoral fellowship to carry out research under the mentorship of dr. andrew wickert at the university of minnesota (umn) and dr. isaac larsen at the university of massachusetts-amherst (umass). this project aims to understand how landscapes buried by recent sediments evolve over time. rivers and their networks drive change in landscape evolution; they reorganize in response to changing climate, tectonics, and rock type, drastically restructuring the earth's surface. field observations have shown that a rock's susceptibility to erosion exerts control in determining how rivers erode into landscapes, an assumption based in the idea that landscapes are made of a single material. because natural rivers cut through multiple materials, it is important to study landscapes with contrasting erodibilities. this project focuses on regions that were previously glaciated where ancient river networks are buried

under tens to hundreds of meters of sediments deposited by glaciers. after burial, a new river network is established on the surface that may have a geometry that is quite different from the ancient river network. as rivers erode into the glacial sediments, they re-expose the old landscape, triggering a competition between the ancient and new river networks. using numerical models and field techniques, the pi will (1) determine important metrics that control the outcome of these competing networks and (2) predict timescales required for glacial sediments to be fully removed. because contrasts in erodibility are common in other landforms, this research will provide important insight into how the structure of the rock below our feet determines rivers formation and landscape evolution in a broad spectrum of geologic settings. the pi also aims to promote earth science education and **\*\*diversity\*\*** by designing interactive numerical models/games about river evolution. at umn and umass, dr. kwang will collaborate with local girls inc. organizations to develop summer workshops for eureka!, a program that aims to close the gender-gap in stem. in addition, the pi will co-mentor an undergraduate research student with dr. phillip larson at the minnesota state university.

landscapes dissected by dendritic networks are ubiquitous across the continental surfaces of earth. understanding how these geopatterns emerge and reorganize reveals how geomorphic processes create landforms. drainage networks seldom change in landscapes that are in dynamic equilibrium, but drainage networks are actively forming and reorganizing in landscapes in disequilibrium. regions in the american midwest that were previously glaciated are classic examples of disequilibrium landscapes. before pleistocene glaciation, these regions generally contained sedimentary rock dissected by dendritic river networks. after glaciation, the sedimentary rock was buried by quaternary sediments, i.e. till, and essentially, the landscape was reset. such landscapes are ideal locations to study drainage networks because (1) new drainage networks are actively forming on the till-covered surfaces, and (2) old drainage networks from the buried topography are being exhumed. in this region, the pi will use numerical landscape evolution models to test how drainage network reorganization is affected by (1) rock erodibility contrasts between the glacial till and buried sedimentary rock and (2) the orientation of the surface drainage network with respect to

the buried drainage network. the results will also detail a new mechanism for the formation of barbed tributaries, offering a new geologic interpretation for these river network features. using field work and remote sensing, the pi will also calibrate a numerical model to predict timescales that are required for the full evacuation of glacial till from these landscapes. more broadly, the pi anticipates that this research will benefit our understanding of other geologic settings with contrasts in substrate erodibility. field studies have found that variability in erodibility has a first-order control on landscape evolution and morphology, and moreover, it has been determined that substrates with contrasting erodibilities are the norm in terrestrial landforms, not the exception. therefore, this research can provide a transformative insight into how lithologic variation and stratigraphy affect surface processes, drive drainage reorganization, and create geopatterns. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: EAR-PF: Investigating the effects of bedrock dip angle on knickpoint morphology and evolution via flume experimentation and numerical modeling

Awardee: Chilton, Kristin

Amount: \$174,000.00

Abstract: dr. kristin chilton has been awarded an nsf ear postdoctoral fellowship to investigate how the orientation of rock fractures (cracks) in river beds influences the ease with which that rock is eroded (worn away) by flowing over waterfalls (also called knickpoints). knickpoints are often zones of concentrated erosion within rivers and this project will involve creatively designed experiments that examine the role of cracks in controlling river erosion into rock. the results of this study will allow scientists to better predict how earth's surface will change over time, interpret climatic and geologic histories from the landscapes we see today, and improve engineering designs for the safety and longevity of important infrastructure. the work will be carried out at virginia tech and west

virginia university in collaboration with mentors, dr. kyle strom and dr. charles shobe, respectively. dr. chilton's project will also provide opportunities for undergraduate involvement in academic research, support **diversity** in stem fields through summer outreach programs, and introduce a broader audience to earth science topics via educational videos and blog posts focused on river erosion processes. the primary goal of this project is to test how the orientation of discontinuities (which can be fractures, joints, or bedding planes) influences hydraulic plucking of bedrock blocks within knickpoints, and therefore knickpoint morphology and evolution. this will be accomplished via a series of flume experiments, which will use stacked porcelain tiles to simulate layered sedimentary bedrock at various dip orientations, coupled with continuous monitoring of knickpoint morphology, retreat rate, and plucking events. the results of the flume experiments will then be integrated into numerical landscape evolution models to expand implications to broader spatial and temporal scales. this investigation will fill a critical gap in our understanding of the fundamental controls on bedrock channel morphology and fluvial incision processes, improve robustness of landscape evolution models by incorporating specific bedrock characteristics, and help ensure appropriate interpretation of knickpoints as indicators of climatic and uplift history by characterizing a potential control on knickpoint form and celerity. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: EAR-PF: Morphological and ecological disparity of Spiriferida (Brachiopoda) at local, regional, and global scales

Awardee: Sclafani, Judith A

Amount: \$174,000.00

Abstract: this award is funded in whole or in part under the american rescue plan act of 2021 (public law 117-2). dr. judith sclafani has been awarded an nsf ear postdoctoral fellowship to conduct research, professional development, and outreach activities at the university of california davis under the mentorship of dr. sandra carlson. evaluating changing ecosystems during intervals of climate perturbation in earth's history can offer important clues to how ecosystems might respond to anthropogenic climate change. this project will focus on the recovery of shallow marine seafloor communities after the second largest mass extinction (~440 million years ago) and investigate whether the evolution of certain biological traits correlates with increased abundance and survivorship with ecological communities. results of this work will be incorporated into high school earth science lessons developed in partnership with the bilingual teacher education program at uc davis. shallow marine ecosystems are important for maintaining ocean bio\*\*diversity\*\* and supporting the economic and cultural services derived from nearshore environments. this means that it is important to both better understand the complex ecological dynamics at play and disseminate information to increase the \*\*diversity\*\* of scientists addressing these problems. the specific goal of this study is to focus on the order spiriferida, which was dominant in the middle-late paleozoic, to: 1) determine whether morphospace occupation is correlated with environmental affinity from global occurrences, and 2) quantify abundance along an environmental gradient from regional stratigraphy. this study will generate substantial new specimen and field-based data about spiriferida from both continental/global and local/regional scales to examine if data, analyses, and results obtained at smaller scales can be meaningfully extrapolated to trends at larger spatial scales. combining data from multiple spatial and taxonomic scales is necessary to address ecological hierarchical scaling in the fossil record and understand the fidelity between global phanerozoic

trends and local specimen and field-based data. studies of the relationship between local sections and global hypotheses are needed to understand the macroecological and macroevolutionary processes responsible for ocean ecosystem structure, stability, and collapse. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: EAR-PF: Mammals as sentinels of biotic recovery and the topographic diversity gradient in the aftermath of the Cretaceous?Paleogene mass extinction

Awardee: Weaver, Lucas N

Amount: \$174,000.00

Abstract: this award is funded in whole or in part under the american rescue plan act of 2021 (public law 117-2). dr. lucas n. weaver has been awarded an nsf ear postdoctoral fellowship to investigate the ecological recovery of mammals during the cretaceous?paleogene (k?pg) mass extinction event. insight from other environmental catastrophes in earth?s past can provide information about the current environmental crisis. additionally, impacts of environmental disturbances are not equal across time and space; therefore, it is important to see how resilient or susceptible species are to extinction in different temporal and geographic settings. the k-pg mass extinction event, which occurred 66 million years ago and is famous for leading to the extinction of

the dinosaurs, is similar to the kind of extinction seen today. towards this end, this project aims to study how mammal communities (including the ancient ancestors of the group to which humans belong) recovered from the k?pg mass extinction over the first 1 million years of the ?age of mammals,? in the denver basin of colorado. mammals are often used as ?canaries in the coal mine? for ecological health because environmental variables such as temperature and moisture are related to mammals? ecological health. the work is based on the hypothesis that the rocky mountains acted as a buffer during the k?pg mass extinction and allowed more mammalian species to survive and diversify in a post-dinosaur world. given that the earth is likely in the midst of a sixth mass extinction event in its history, this study provides crucial insight into which ecosystems are at greatest risk, and which ecosystems are better able to ?weather the storm.? broader impacts of this work include working with the denver museum of nature and science to disseminate results to a broad audience through their exhibits; mentoring of undergraduates at university of michigan and city university of new york, and development of curriculum for high school students. this project aims to investigate the spatial and temporal heterogeneity of mammal recovery after the cretaceous?paleogene (k?pg) mass extinction (66 million years ago) in the denver basin of colorado. denver basin fossil localities are highly resolved chronostratigraphically, allowing precise correlation of the pattern and timing of biotic recovery in different paleogeographic regions of the basin during the first ~1 million years of the paleogene. since mountainous regions today are bio\*\*diversity\*\* hotspots, this project is based on the hypothesis that mammal communities close to the emerging rocky mountains (1) were more resistant to the k?pg mass extinction, and (2) recovered more quickly in its aftermath. to explore these hypotheses, the work will quantify and compare the taxonomic (richness, relative abundance), dietary (inferred via tooth shape), and body mass (inferred via tooth size) \*\*diversity\*\* between two stratigraphic sequences of fossil mammal assemblages: (1) close to and (2) far from the rocky mountain front range. this project will involve field and laboratory work and will use new paleoecological methods to infer community-level mammal \*\*diversity\*\* patterns through time. this study will be the first to (1) look at spatial

heterogeneity in post-k?pg mammalian recovery in high resolution and (2) explore whether mountain habitats were a driver of early mammalian **\*\*diversity\*\***. these results will help identify geospatial features that promote biological community resilience/reassembly after environmental disasters, and will shed light on the tempo and mode of the post-k?pg radiation of mammals, which ultimately led to the distribution of terrestrial bio**\*\*diversity\*\*** we see today. this work will also integrate data from the mammal fossil record with the broader vertebrate and plant fossil record, and with paleoclimate proxies. this novel multidisciplinary approach will allow collaboration with other scientists to track whole-ecosystem recovery in the aftermath of the k?pg mass extinction. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: MRA: Distributions of Macrofungi: Quantifying Ecosystem and Climate Drivers of Fungal Reproduction

Awardee: Denver Botanic Gardens

Amount: \$173,853.00

Abstract: fungi are essential components of terrestrial ecosystems worldwide. many fungi produce fruiting bodies in the form of mushrooms. these mushroom-forming fungi are key to forest nutrient cycling and, in association with plants, range from beneficial symbionts to pathogens. yet, we know very little about how regional, landscape, and local factors such as fire combine to affect the distributions of mushroom-forming species, nor how such distributions may be changing with a shifting climate. understanding mushroom distributions is particularly challenging because these fungi spend most of their lives as branching filaments of asexual cells (hyphae) below the soil, and their presence only becomes known if and when they produce a mushroom. recent work has shown that some fungi may occur as hyphae inside plants thousands of kilometers outside their known ranges, which are based on their sexual reproduction (i.e., mushrooms). these extended ranges of fungal hyphae suggest that different factors drive the distributions of life stages of these fungi, complicating efforts to forecast how fungi will respond to changing environments. this research will

examine the distributions of mushroom-forming fungi across the united states by combining mushroom collections with sampling of fungal dna in soils, litter, plant tissues, and the air, at study locations in eight different states (ak, az, co, fl, ks, nh, mn, or). information at each site such as climate, plant communities, fire and soils will then be used to determine the conditions under which particular fungi are able to sexually reproduce and where they can only live as hyphae. the project will connect scientists with more than a thousand community members from mushroom clubs, local schools, and museums who will be involved in collecting mushrooms and working with fungal dna for scientific purposes. using the extensive climatic and geographic scope of the study, containing diverse plant communities and fire disturbances, we will test how environmental variables at multiple scales influence distributions of sexual and asexual stages of fungi. we will also determine whether occurrence of a fungus in one stage (e.g., mushrooms) is predictive of its occurrence in other substrates at a site (e.g., soils, air, or plant tissues), allowing improved sampling schemes for fungi. together, this study will build the most complete picture to date of how macrofungal communities and their relationships change across climate gradients, thus building capacity to predict changes in fungal distributions and ecosystem processes under changing climate. further, unprecedented fires in recent years have placed fire ecology in the public eye like never before, such that expanding understanding of fire as a driver of cryptic aspects of bio\*\*diversity\*\* and ecosystem dynamics is timely and of broad interest. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Examining the Vulnerability and Recovery of Small Farms to Natural Hazards and the Impact to Rural Community Resilience

Awardee: University of Nebraska-Lincoln

Amount: \$173,572.00

Abstract: this disaster resilience research grant (drrg) project contributes to the advancement of national health, prosperity and welfare by creating new knowledge on disaster recovery for the agricultural industry. despite the criticality of agriculture to u.s. and global food production, the lack of economic **\*\*diversity\*\*** and prevalence of agriculture in many rural areas, particularly in the central us, is theorized to be a major contributor to low disaster resilience. resilience is a complex function of socio-economic dimensions and the built environment; and the population, economics, and physical infrastructure that comprise agricultural regions are distinct from the urban and suburban areas that are the common focus of most disaster and community resilience studies. this research generates a fundamental understanding of the resilience of farms and agriculture-prevalent rural communities in the face of severe windstorms, which will be of broad benefit to society and to national resilience. the research team will identify, evaluate, and recommend actions to enhance resilience of farms. to maximize the impact of these findings, the team will partner with the extension disaster education network for outreach and technology transfer. implementation of these mitigation measures can transform the disaster resilience of rural and agricultural regions, safeguarding the lives of citizens, regional and national economies, and global food production. the long-term goal of this research is to enhance the resilience of rural communities to natural hazards, which requires state-of-the-art research on the infrastructure that support farm operations, the recovery processes of individual farms, and the interaction of individual farms within the regional agricultural economy. as a first step towards enhancing rural resilience, the interdisciplinary team will conduct a three-year research project carefully tracking resilience from hazards to structures to farms to communities. the project is characterized by two primary goals. the first goal is to generate a fundamental understanding of the vulnerability and recovery of farms following windstorms through longitudinal reconnaissance of impacted agricultural communities, surveys of impacted farmers, correlation of hazard intensity with infrastructure response, and the examination of the linkages between recovery of individual infrastructure with farm-level recovery. the second goal is to develop and validate a risk-informed resilience assessment framework comprised of a farm-level resilience factors and

community-level economic analyses to support decisions on business continuity and infrastructure investment for farms and the broader agriculture-prevalent rural communities. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: BPC-AE: STARS: Catalyzing Action-Oriented Academic Communities for Broadening Participation in Computing

Awardee: University of North Carolina at Charlotte

Amount: \$173,277.00

Abstract: it is critical to address the longstanding issue of underrepresentation of women, black, and hispanic students in computing degree programs to provide an equitable foundation for all to participate in our society and the global economy as controllers and creators of technology, and to advance the preparation of a diverse, innovative, and competitive tech workforce. building on the prior success of the stars computing corps alliance for broadening participation in computing, the goal of the stars catalyst project is to: 1) increase the number of women, black, and hispanic students that persist in computing degree programs, and 2) advance the careers of students and faculty from groups that have been historically underrepresented in computing. through research and evaluation around stars catalyst activities, this project will advance knowledge about practices designed to increase persistence and support career advancement in computing for college computing students and faculty, particularly for those from underrepresented and intersectional groups in computing. the stars catalyst alliance is a collaborative effort across temple university, north carolina state, kent state, florida state university, morgan state, and university of north carolina charlotte. the stars computing corps alliance for broadening participation in computing (bpc) engages computing faculty and students at colleges, universities, and community colleges in a community of practice with a shared commitment to take action to advance **\*\*diversity\*\***, equity, and

inclusion in computing. stars computing corps conferences, communities, and networks create significant institutional and human resources that can expand bpc research to a larger audience of researchers, educators, administrators, cs departments, and k-20 students, and can dramatically increase the number of people taking action in bpc efforts. prior results show that the stars computing corps alliance increases intentions to persist in computing among stars students and faculty, with enhanced outcomes for black students and faculty. this project will significantly extend the stars alliance to expand upon those impacts, by 1) including new partners that expand the reach of stars and that emphasize participation of black and hispanic students and faculty, particularly from emerging hispanic serving institutions and community colleges, 2) creating new program elements that test new and propagate evidence-based bpc practices within computing departments, and 3) leveraging partnerships to support identity-focused affinity groups, and 4) developing stars alumni groups employed in industry positions to promote transition to and retention within the tech workforce. extensions to the stars leadership corps program, stars launch program, and the stars celebration conference will serve to develop and propagate evidence-based approaches aimed at improving the teaching and learning of computing for black and hispanic students and build evidence of their effectiveness, and the respect research conference will continue to advance peer-reviewed bpc scholarship. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Core Support for Future Earth International Global Change Research

Awardee: George Mason University

Amount: \$172,761.00

Abstract: this project supports the us secretariat of future earth. future earth harnesses the insights and capacity of the global scientific community to address global problems, like a warming and

increasingly unstable climate, and a rapid loss of bio\*\*diversity\*\* and ecosystem services. the future earth effort is based on the recognition that modern global change challenges require coordinated research efforts bringing together the world's best researchers in the natural, social, behavioral, and engineering sciences, and connecting these researchers with the needs and capacities embedded within a wide range of stakeholder institutions and communities. the secretariat leads and co-leads core functions that include research enabling, networks and capacity, information technology, and communications. in addition, the us global hub leads the evolution and growth of future earth's global efforts and directs many of future earth's core global initiatives, including a flagship capacity building program, communications products, and collaborative data-platforms. future earth provides a critical service to the science community by advancing global change science in the us and around the world, and by supporting the full range of research modalities from fundamental disciplinary research to transdisciplinary research. by connecting research across geography and discipline, the project supports the emergence of novel, integrative scientific ideas. by elevating the spread and impact of scientific results and connecting these results with constituencies in business, government, and civil society, future earth's work supports decision making around the world. it also connects us researchers with a vast and rapidly growing network of leading international scholars in global change research and provides direct access to new knowledge and initiatives. this work includes a broad range of communication capacities in the us and around the world, like the establishment of the sustainability research and innovation congress, the first global convening that brings the global change research and innovation communities together, on an annual basis. the future earth us global hub has also established partnerships to build and diversify the next generation of global change researchers through an internship program. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Cell biology of cnidarian-dinoflagellate symbiosis: Signaling, regulation and host response pathways

Awardee: University of Florida

Amount: \$172,749.00

Abstract: coral reef ecosystems are bio\*\*diversity\*\* hotbeds that provide valuable environmental and economic services to half a billion people globally, including millions in the us. reefs are faced with almost complete destruction by the end of the century due to global warming unless humanity can cap global temperature rise. coral biologists are working together to develop a broad array of solutions to help with the coral reef crisis. as a part of these efforts, discovery has a critical role to play. corals are an intimate symbiosis between the coral animal and millions of single-celled algae that reside inside of coral cells. the algae provide photosynthetically derived sugars to the host in return for nutrients and a habitat. dysfunction of the symbiosis, caused by global warming and other human-caused impacts, is the driver of coral bleaching and is causing widespread reef degradation globally. this award will examine the cellular and molecular mechanisms governing the coral-algal partnership. the researchers will use state-of-the-art cellular and molecular tools to discover the chemical signals exchanged between the partners. they will describe the role of the algae in early development of the host and explore the mechanisms of inter-partner regulation during healthy symbiosis and bleaching. the award includes extensive education and outreach aims. undergraduate, graduate student and postdoctoral fellow training is central to the work. finally, the researchers will engage directly with the public, both in oregon and florida, through a variety of activities aimed at illustrating the importance of corals to science and society. many cnidarians, including corals and anemones, engage in a symbiosis with photosynthetic dinoflagellates (family symbiodiniaceae) that together form the trophic and structural foundation of the coral reef ecosystem. despite the importance of corals to coral reefs and the threatened state of coral reef health in an era of climate change, we have an incomplete understanding of how the partnerships are established, regulated and maintained. the researchers will examine inter-partner signaling and

regulation during onset, maintenance and breakdown of cnidarian-dinoflagellate symbioses. experiments will be conducted largely in a laboratory-based sea anemone-symbiodiniaceae model system. the team will carry out the following specific aims: aim 1: characterize algal-host signaling dynamics during onset, maintenance and breakdown of symbiosis by molecular glycan profiling of different symbiont species and by using a unbiased dna aptamer technique to identify surface determinants of symbiotic algae. aim 2: describe the spatio-temporal patterning of symbionts in hosts and their impact on host development and growth by examining the role of symbiosis on polyp development and exploring the dynamics of symbiont invasion in developing polyps. aim 3: examine the role of host response pathways in regulation of symbiosis by measuring changes in nadph oxidase activity and sphingosine rheostat signaling in host tissues both during onset of symbiosis and in dysbiosis. the researchers will develop a course-based undergraduate research experience (cure) based on the sea anemone-symbiodiniaceae model system and they will examine the effectiveness of the cure in student learning and in building of science identity. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Digitization TCN: Extending Anthophila research through image and trait digitization (Big-Bee)

Awardee: Arizona State University

Amount: \$171,235.00

Abstract: declining populations of bees impact plant-pollinator interactions in both natural and agricultural systems. while bees and other insects pollinate most wild plants, and are critical to sustain a large proportion of global food production, they are decreasing in both numbers and **\*\*diversity\*\***. our understanding of the factors driving these declines is limited because we lack sufficient data on the distribution of bee species, and on the behavioral and anatomical traits that

may make them either vulnerable or resilient to human-induced environmental changes, such as habitat loss and climate change. fortunately, wild bees have been collected by researchers and deposited in natural history collections for over 100 years, retaining a wealth of associated attributes that can be extracted from specimen images. this project will digitally capture data and images from these historic specimens, develop tools to measure bee traits from these images, and generate a comprehensive bee trait and image dataset to measure changes through time. this will increase our understanding of specific traits that put bee species at risk of decline - a critical need for both sustaining our agricultural economy and the conservation of our natural resources. in addition, the large image datasets created by this project can be used for new artificial intelligence identification tools that will help improve our future pollinator observation and monitoring efforts. the big-bee thematic collection network (big-bee tcn) will create over one million high-resolution 2d and 3d images of bee specimens, representing over 5,000 worldwide bee species, including all of the major pollinating species of the united states. the big-bee network includes 13 institutions and partnerships with us government agencies. novel mechanisms for sharing image datasets will be developed and datasets of bee traits will be available through an open data portal, the bee library, for research and education. the big-bee project will engage the general public in research through community science via crowdsourcing trait measurements and data transcription from images. in addition, training and professional development for natural history collection staff, researchers, and university students in data science will be provided through the creation and implementation of workshops focusing on bee traits and species identification. all data resulting from this award will be shared with and publicly available through the national digitized biocollections resource, [idigbio.org](http://idigbio.org). this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: CNS Core: Small: Adaptive Smart Surfaces for Wireless Channel Morphing to Enable Full Multiplexing and Multi-user Gains

Awardee: University of Colorado at Denver-Downtown Campus

Amount: \$170,000.00

Abstract: the connectivity solutions need to scale up massively to support unprecedented exponential growth in data rates and the number of devices. the primary approach to meet the demands has been to upgrade the infrastructure, such as adding base stations with multiple antennas and/or upgrading clients. unfortunately, these approaches have fallen short of their goal as in practice, the channels between users and base stations have limited scattering or richness to enable spatial multiplexing, and users are not sufficiently separated in the spatial domain. this proposal will shape the channel to unlock the full potential of wireless networks without requiring updating the base station or user device at a low cost in terms of power and expense. the proposed research aims to adaptively modify and morph the wireless medium using smart passive reflector surfaces to materialize the spatial multiplexing gains. the underlying idea is to use smart reflectors to create additional channel **\*\*diversity\*\*** to manipulate the received signal before reflecting it to

minimize interference at the receivers. the research brings together pis and techniques from communications theory, networked system design, and antenna design to build scalable and low-cost wireless networks. the project also proposes a synergistic educational and outreach plan that leverages the technical work to build exciting demos for undergraduate and k-12 classrooms. for example, a smart surface-based demo, which increases the data rate and coverage of current wi-fi devices, will introduce students to the wonders of engineering in a pragmatic yet compelling way, with the hope of increasing **\*\*diversity\*\*** in stem-related education environments. the proposal would develop smart surface designs capable of morphing the channel, and develop the hardware prototype and algorithms to provide coverage and multiplexing gains to support massive numbers of users and the exponential increase in data rates. the designed smart surface with fine-grained control would allow us to morph the wireless channel or environment to increase the **\*\*diversity\*\*** and multiplexing gains as deemed necessary during optimization. we further establish smart surface placement theory and algorithms and quantify the performance-size trade-offs. we develop low-overhead channel estimation and low-latency optimization algorithms for the base station to support temporal channel changes and improve the data rate and connectivity. the proposed effort would develop the theory and algorithms for multi-user setups to ensure scalability with smart surfaces. the proposed work would enable the first low-cost, practical smart surface and algorithms supporting high-mobility users with significant data-rate improvements. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Frameworks: Convergence of Bayesian inverse methods and scientific machine learning in Earth system models through universal differentiable programming

Awardee: University of Colorado at Boulder

Amount: \$166,590.00

Abstract: understanding and quantifying parameter sensitivity of simulated systems, such as the numerical models of physical systems and mathematical renderings of neural networks, are essential in simulation-based science (sbs) and scientific machine learning (sciml). they are the key ingredients in bayesian inference and neural network training. seizing on the opportunity of emerging open-source earth system model development in the julia high-level programming language, this project is endowing these open-source models with automatic differentiation (ad) enabled derivative information, making these converging data science and simulation-based science tools available to a much broader research and data science community. enabling a general-purpose ad framework which can handle both large-scale earth system models as well as sciml algorithms, such as physics-informed neural networks or neural differential equations, will enable seamless integration of these approaches for hybrid bayesian inversion and bayesian machine learning. it merges big data science, in which available data enable model discovery with sparse data science, and the model structure is exploited in the selection of surrogate models representing data-informed subspaces and fulfilling conservation laws. the emerging julia language engages a new generation of researchers and software engineers, channeling much needed talent into computational science approaches to climate modeling. through dedicated community outreach programs (e.g., hackathons, minisymposia, tutorials) the project team will be working toward increasing equity, **\*\*diversity\*\***, and inclusion across the participating disciplines. the project is

developing a framework for universal differentiable programming and open-source, general-purpose ad that unifies these algorithmic frameworks within julia programming language. the general-purpose ad framework in julia leverages the composability of julia software packages and the differentiable programming approach that underlies many of the sciml and high-performance scientific computing packages. compared to most current modeling systems targeted for hpc, julia is ideally suited for heterogeneous parallel computing hardware (e.g., cuda, rocm, oneapi, arm, powerpc, x86 64, tpus). the project is bringing together expertise in ad targeted at earth system data assimilation in high performance computing environments with sciml expertise. the project team is working with the julia computing organization and package developers to ensure sustainability of the developed frameworks. the project's earth system flagship applications consist of (i) an open-source, ad-enabled ocean general circulation model that is being developed separately as part of the climate modelling alliance (clima), and (2) an open-source, ad-enabled ice flow model. each of these application frameworks is being made available to the community for science application, in which derivative (gradient or hessian) information represent key algorithmic enabling tools. these include sciml-based training of surrogate models (data-driven and/or model-informed), parameter and state estimation, data assimilation for model initialization, uncertainty quantification (hessian-based and gradient-informed mcmc) and quantitative observing system design. academic and industry partners are involved, who are using the frameworks for developing efficient power grids, personalized precision pharmacometrics, and improved eeg design. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Dimensions US-China: Collaborative Research: Consequences of diversity in Asian and American oak syngameons for functional variation, adaptation and symbiont biodiversity

Awardee: Duke University

Amount: \$164,419.00

Abstract: the world's approximately 425 oak species maintain species identity even while exchanging genes with their close relatives through hybridization. this history of evolution and genetic exchange has shaped the bio\*\*diversity\*\* of northern hemisphere ecosystems. oaks are ecologically diverse, with related species often growing in close proximity but specializing on areas of the forest landscape that differ in soil texture and moisture level or in the frequency of natural fires. gene exchange can move such ecological specializations between oak species, broadening their ranges and ability to respond to climate change. the impacts of these genetic exchanges may extend beyond the oaks themselves. oaks host an estimated 1000 gall wasp species worldwide and highly diverse communities of fungi associated with their roots (as mycorrhizae) and inside their leaves (as endophytes). using paired field surveys and common garden experiments the pis will evaluate the effects of hybridization and introgression on the genetic, phylogenetic, and functional \*\*diversity\*\* of focal oak species and their symbionts in the us and china. this work will also provide inquiry-based k-12, undergraduate, and graduate education; critical natural history training to the public through a community-science initiative in oak phenology; and publications that will bring research to public audiences. two interdisciplinary teams of researchers, one based in the us and one in china, will investigate how genomic, functional, and phylogenetic \*\*diversity\*\* of oak trees shape the mycorrhizal fungi, endophytic fungi, and gall wasp and other insect communities that associate with them. research will focus on two related groups of interbreeding species: bur oak (*quercus macrocarpa*) and relatives in the us and bao li (*quercus serrata*) and relatives in china. the project has three objectives, each conducted in parallel in china and the u.s. in objective 1 the teams will perform range-wide phylogenomic surveys of natural populations to reconstruct genomic mosaics, characterize geographic patterns of leaf functional traits, and characterize functional and phylogenetic \*\*diversity\*\* of associated mycorrhizal fungi, leaf endophytic fungi, and gall wasps. in objective 2 common gardens will be planted across climatic gradients to evaluate the effects of genetic variation and population differentiation on oak functional and spectral traits and relative

fitness in different climates, and how these influence the phylogenetic and functional **diversity** of oak-associated fungal and insect communities. in objective 3 the teams will use a second set of common garden experiments to evaluate how plant community and phylogenetic **diversity** affects focal oak species genetic, phylogenetic, and functional **diversity**. the project will provide an integrative perspective on how oak **diversity** within and among species impacts the broad **diversity** of oak-dominated ecosystems across the northern hemisphere. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: EAGER: Self-incompatibility in elderberry

Awardee: University of Missouri-Columbia

Amount: \$162,000.00

Abstract: roughly half of the approximately 352,000 species of flowering plants on earth possess mechanisms that favor cross-pollination. this reproductive strategy is crucial for generating and sustaining the genetic **diversity** that plants need to survive and adapt. humans rely on plant **diversity** both directly, for crop improvement, and indirectly, for ecosystem support. many plants have evolved ways to recognize and reject self-pollen and pollen from close relatives. these so-called "self-incompatibility systems" are among the most common and effective mechanisms that prevent self-pollination and favor cross-pollination. to date, the genes controlling self-incompatibility, called s-genes, have been identified in only three systems that operate in a handful of plant families. this project will identify s-genes in elderberry, an emerging specialty crop rich in antioxidants that is used in wine, supplements, and other products. candidate genes were identified using a novel approach prioritizing dna sequence differences that could relate to pollen recognition as well as expression data. experiments will evaluate these candidate genes by testing whether the presence or absence of particular s-genes reliably predicts what types of pollen are

accepted or rejected. other experiments will identify additional s-gene variants. the approach used to identify elderberry s-genes may be applied to additional self-incompatibility systems and, thus, further contribute to understanding maintenance of plant **diversity**. self-incompatibility (si) systems are among the most important genetic mechanisms plants use to control mating. typically, the genes controlling si, s-genes, have numerous allelic variants, and, basically, si allows plants to reject pollen from potential mates with similar alleles. si species are obligate outcrossers because self-pollen always has the same s-alleles as the pistil. notwithstanding their outsized importance for plant **diversity**, evolution and adaptability, s-genes have only been identified in a handful of si systems. here, the overall goals are to elucidate a new si system, identify the controlling s-genes, and facilitate their use in the scientific and agriculture communities. we characterized si in elderberry (*sambucus canadensis*) and used rnaseq to identify candidate s-genes. genetic experiments will ascertain whether these candidate s-genes truly control si in elderberry. four populations segregating for distinct s-allele candidates will be genotyped and test pollinated to determine whether they reject pollen from plants bearing the same alleles. elderberry is an emerging specialty crop valued for potential health benefits, and additional s-alleles will be identified in elderberry and related plants to support the elderberry improvement community. specifically, the project will allow breeders and producers to predict the crossing behavior of commercial varieties. project activities related to elderberry production and improvement will be broadly disseminated via presentations, video, and extension publications. the project also will contribute to human resource development by providing undergraduate research training in both laboratory- and field-based plant science. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Revitalizing a field wireless network for research, education and outreach at the Harvard Forest

Awardee: Harvard University

Amount: \$161,588.00

Abstract: research in environmental science is increasingly dependent on sensor arrays, computer networks, and near-real-time data processing and visualization. at the harvard forest, the field wireless network extends the university computer network into the research forest where there is little or no cell phone reception. since 2010 the field wireless has supported a wide range of research projects with investigators from many different institutions, resulting in (as of march 2021) 27 datasets publicly available online and 291 related scientific publications. many of these projects are long-term experiments associated with the lter and ameriflux networks; others are short-term projects by researchers drawn to the forest because of its infrastructure and long-term data. the field wireless enables scientists to monitor and control their equipment and collect data remotely, reducing travel costs and loss of data from problems that would otherwise have gone undetected since the last in-person visit. in recent years, and especially after the onset of the pandemic, the field wireless has supported virtual field trips and remote instruction, broadening the audience and geographic reach of the forest's education and outreach efforts. this project will greatly improve the performance of the field wireless by significantly increasing network bandwidth and the number of sites with wi-fi capability. these improvements will enable exciting new possibilities for research, including data collection from more extensive sensor arrays, video streaming, and near-real-time ecological forecasting. they will also expand the number and **\*\*diversity\*\*** of field sites available for remote instruction, especially benefiting groups that are underrepresented in the sciences and often unable to visit the forest in person due to distance, cost, or physical accessibility. virtual field trips and remote learning via the field wireless will remain a major means for reaching a broader audience long after the pandemic has receded. this project will expand and revitalize the harvard forest field wireless network, which was commissioned in 2010 with support from nsf, doe, and harvard university and is jointly managed by the forest and harvard network operations. the field wireless currently provides internet access to field sites spread across the 375-ha prospect hill tract,

including 10 major sites with a walk-in equipment shed, 24-port network switch, and wireless access point (ap), and 10 minor sites with an instrument enclosure and data logger or phenology camera. sites are connected by carrier-grade unlicensed spread-spectrum radios: 5.8 ghz radios for tower-to-tower communications with unobstructed line of sight and 900 mhz radios for tower-to-ground communications through the forest canopy. network bandwidth is limited by the radios and ranges from 2 to 5 mbps, depending on the site. a dedicated virtual private network (vpn) allows researchers to access their equipment remotely when not at the forest. this project will retain the basic design of the field wireless but greatly improve its performance by (1) replacing the current radios (which are no longer available) with new radios at least an order of magnitude faster, (2) adding two new experimental sites, (3) adding wi-fi capability at nine sites that currently lack it, and (4) augmenting wi-fi at four sites that are regularly used for education and outreach. the resulting increase in network bandwidth and wi-fi availability will significantly improve support for data-intensive research projects, virtual field trips, and remote instruction; by improving communications, it will also enhance safety for students and scientists working in the prospect hill tract of the harvard forest (<https://harvardforest.fas.harvard.edu>). this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Digitization TCN: Extending Anthophila research through image and trait digitization (Big-Bee)

Awardee: Regents of the University of Michigan - Ann Arbor

Amount: \$160,392.00

Abstract: declining populations of bees impact plant-pollinator interactions in both natural and agricultural systems. while bees and other insects pollinate most wild plants, and are critical to sustain a large proportion of global food production, they are decreasing in both numbers and

**\*\*diversity\*\***. our understanding of the factors driving these declines is limited because we lack sufficient data on the distribution of bee species, and on the behavioral and anatomical traits that may make them either vulnerable or resilient to human-induced environmental changes, such as habitat loss and climate change. fortunately, wild bees have been collected by researchers and deposited in natural history collections for over 100 years, retaining a wealth of associated attributes that can be extracted from specimen images. this project will digitally capture data and images from these historic specimens, develop tools to measure bee traits from these images, and generate a comprehensive bee trait and image dataset to measure changes through time. this will increase our understanding of specific traits that put bee species at risk of decline - a critical need for both sustaining our agricultural economy and the conservation of our natural resources. in addition, the large image datasets created by this project can be used for new artificial intelligence identification tools that will help improve our future pollinator observation and monitoring efforts. the big-bee thematic collection network (big-bee tcn) will create over one million high-resolution 2d and 3d images of bee specimens, representing over 5,000 worldwide bee species, including all of the major pollinating species of the united states. the big-bee network includes 13 institutions and partnerships with us government agencies. novel mechanisms for sharing image datasets will be developed and datasets of bee traits will be available through an open data portal, the bee library, for research and education. the big-bee project will engage the general public in research through community science via crowdsourcing trait measurements and data transcription from images. in addition, training and professional development for natural history collection staff, researchers, and university students in data science will be provided through the creation and implementation of workshops focusing on bee traits and species identification. all data resulting from this award will be shared with and publicly available through the national digitized biocollections resource, [idigbio.org](http://idigbio.org). this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: A Self-Study of Contingent Faculty and their Impact on Undergraduate STEM Education at a Research-Intensive Institution

Awardee: William Marsh Rice University

Amount: \$160,365.00

Abstract: this project aims to serve the national interest by addressing contingent faculty labor equity to improve stem education. contingent faculty comprise 69.5% of higher education instructional faculty nationwide. they include both part-time and full-time faculty who are appointed off the tenure track. contingent faculty play a critical role in undergraduate stem education and hold great potential for advancing student success as well as institutional commitments to **\*\*diversity\*\***, equity, and inclusion. transforming faculty labor conditions to better support contingent faculty, particularly at research-intensive institutions, is critical for educating an increasingly diverse population and providing equitable stem education. this capacity building project will offer a model self-study of the role of contingent faculty within university structures. the study has potential to deepen and transform current understandings of faculty roles at the university. project outcomes include: (i) identifying a replicable set of institutional changes that enhance stem education; (ii) revealing institutional models and best practices for achieving equitable stem educational outcomes with a diverse faculty workforce; and (iii) identifying a theory of change that will be generalizable to similar research-intensive institutions. the goal of this project is to use a grounded theory approach to identify how research-intensive institutions can transform organizational structures, processes, and policies to ensure that contingent faculty enhance stem education, educational equity, and institutional reputation. as the project's scope focuses on systemic, transformational change, the project team will consist of both tenured and contingent stem faculty, upper administration, and staff who support undergraduate teaching and learning. the project will conduct a self-study that employs a mixed method approach, including institutional data analysis and surveys, interviews, and focus groups with faculty and administrators, to understand how the labor conditions of contingent faculty

affect stem education. the project will engage in four key activities: 1) an assessment of the institutional and individual factors at the proposing institution that affect contingent faculty labor conditions and perceptions; 2) an analysis of the impact of contingent faculty labor conditions on stem teaching and learning at the proposing institution; 3) identification of a theory of change that provides a framework for interventions and institutional transformation of the contingent faculty role at research-intensive institutions; and 4) identification of and collaboration with an institutional partner to build upon the foundation laid through the self-study. this project will yield new information on how contingent faculty agency and integration in research-intensive institutions affect stem outcomes and address a gap in understanding of the institutional processes, structures, resources, and policies necessary to ensure that contingent faculty enhance stem education. focus on the research-intensive context will advance understanding of the impact of contingent faculty on student learning to an institutional type that has received less attention in the literature despite a critical role in preparation of the professional stem labor force. the nsf iuse: ehr program supports research and development projects to improve the effectiveness of stem education for all students. through the institutional and community transformation track, the program supports efforts to transform and improve stem education across institutions of higher education and disciplinary communities. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: The geological and paleoecological contexts of early Miocene hominoid evolution

Awardee: Baylor University

Amount: \$159,211.00

Abstract: this award is funded in whole or in part under the american rescue plan act of 2021 (public law 117-2). this project examines the roles of time and environment in the adaptive evolution of early

apes by advancing knowledge about the chronology, paleoecology, and species **diversity** for a set of geographically restricted fossil localities. the research design includes a series of fossil excavations to uncover new evidence of early apes and their habitats, combined with laboratory analyses designed to aid in synthesizing and interpreting these discoveries. the scientific importance of this project lies in documenting early ape adaptive **diversity** within specific, highly-resolved chronological and ecological contexts, with major downstream implications for interpreting the origin and diversification of later apes, including hominins. more broadly, this project expands participation in research through training opportunities targeted to underrepresented groups, enhances scientific infrastructure by digitizing invaluable but currently inaccessible field records, and increases public engagement with science through outreach activities aimed at museums and public schools. fossil and molecular evidence indicate that the major lineages of humans and apes diverged during the early miocene (ca. 23-16 ma). the **diversity** of ape species and adaptations during that time greatly exceeds modern variation in this group making it difficult to interpret the evolutionary sequence and ecological contexts in which the suite of features shared by living apes and humans appeared. this project is organized around the central question: are differences among early apes tied to differences in paleoenvironments, ages, or both? to clarify these relationships, researchers pursue three specific aims: (1) establishing a rigorous chronology of early ape fossil sites; (2) generating high-resolution paleoecological reconstructions for undersampled ape localities; and (3) documenting the **diversity** of ape species during the early miocene. fossil excavations are conducted at a series of outcrops to better document ape **diversity**, geological contexts, and habitat parameters. the project employs radiometric and magnetostratigraphy at correlated stratigraphic sections (aim 1); sedimentological, isotopic, and paleontological analyses (aim 2); and comparative, morphometric, and phylogenetic analyses of new fossil ape specimens (aim 3). integration of these study results can enable the researchers to contextualize the timing and ecological parameters associated with the emergence of key characteristics in the ape and human lineage, and to subsequently interpret how these early miocene primate communities contributed to

the distribution of primates across broad regions. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: PPOSS: Planning: A Disciplined Approach to Scaling in the Post-Moore's Law Era

Awardee: Princeton University

Amount: \$158,700.00

Abstract: general-purpose processor speeds have not increased at their historical rates for over 15 years. designers have instead offered scalable computing systems with additional barriers to realizing the performance gains that once came "for free" with each processor generation. this situation has slowed the progress of all endeavors that involve scalable computing. a disciplined approach to reversing this trend must start and end with a direct engagement with the scalable-system users and programmers faced with these barriers. with this goal, the investigators are performing in-depth face-to-face interviews with a broad set of users. in addition, with these users, the project team is also examining codes, exchanging ideas, and offering assistance. this is producing a deep understanding of how users are coping with their growing demands for computing while computing is placing more demands upon them. the project's novelties are this in-depth study and the resulting formulation of an approach to address the limitations of scalable computing based on real users' needs. the project's impacts are the dissemination of the survey results and a recommended approach forward that restores meaningful layers of abstraction to scalable systems, freeing programmers from being drawn deeper into the complexity of scalable computing while delivering higher performance to them. the investigators performed a similar study in 2011. with this planning grant: (1) they are conducting a more ambitious study with a greater **\*\*diversity\*\*** of subjects. by re-engaging as many 2011 subjects as possible, this becomes a longitudinal study

capable of revealing trends not visible in any single point-in-time study. (2) the investigators are using these interactions to explore transitioning their foundational work to practice, to build a larger team, and to expand the scope of future work. the results of the 2011 study inspired the investigators to produce breakthroughs in speculation, dependence handling, latency tolerance, and automatic parallelization. the 2021 study serves as a vehicle to explore ways to transition these results to practice. (3) the investigators believe that hardware can be more domain-adept without being domain-specific. using prior insights, they are exploring hardware/software concepts that deliver top performance levels without undue programmer burden. by testing these ideas in the context of the study, the investigators can best frame the problem, refine approaches, and test hypotheses in the context of actual needs, opportunities, and constraints. all of these activities ensure that future work in scalable systems will have greater impact. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Quantum Transport in Self-Assembled Hybrid Superlattices

Awardee: Purdue University

Amount: \$158,534.00

Abstract: new phenomena emerge when two semiconductors are brought together in a periodic structure. such semiconducting superlattices have properties not observed in bulk semiconductor crystals. their unique properties have led to novel devices such as tunable optical filters, infrared photodetectors, and quantum cascade lasers. superlattices are expensive to make, requiring ultrahigh vacuum and meticulous layer by layer assembly. the project aims to discover a new type of superlattice based on hybrid perovskites, materials with both organic and inorganic components. hybrid perovskites can be solution processed, allowing for spontaneous assembly into layered nanostructures. their chemical **diversity** can revolutionize superlattice research with a vastly expanded range of materials with varied properties. this research will enable future superlattice devices that are scalable and cost-effective. this project will also provide interdisciplinary training to undergraduate and graduate students, providing them with critical-thinking and problem-solving skills needed for careers in stem and industry. semiconducting superlattices are quantum heterostructures important to condensed matter physics and with applications in advanced electronic technologies. the constituents of the superlattices to date have been limited to inorganic semiconductors, such as GaAs and AlGaAs. this project will investigate quantum transport in a new class of semiconducting superlattices based on Ruddlesden-Popper halide perovskites. the project will employ theoretical and experimental studies in an iterative manner so as to accelerate materials discovery. first principle density functional theory (DFT) calculations will be used to predict materials structures and the optical and electronic properties will be modeled by combining tight-binding models with the DFT calculations. superlattice structures will be prepared by solution processing and self-assembly, allowing for facile tuning of the electronic structure by varying constituents. the design strategy, using semiconducting organic ligands, will create new possibilities for band engineering. electrooptical measurements will be used to identify signatures of semiconducting superlattices such as electronic minibands. complementary electrical characterization will be used to

search for evidence of quantum transport, using optical excitation to generate charge carriers without unintended effects arising from doping. the project will elucidate the properties of 2d perovskite superlattices, differentiate their behaviors from conventional inorganic superlattices, and determine if their optical and electronic properties can be tailored in a controllable manner. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Research Initiation: Social Engagement & Belonging in Academic Makerspaces

Awardee: Western Washington University

Amount: \$158,228.00

Abstract: academic makerspaces provide students with open access to resources that help them develop their problem solving skills, provide opportunities for collaboration, and encourage experimentation and discovery. however, recent research has shown that many makerspace environments do not readily support diverse populations, create tensions between different student groups, and can sometimes lead to a work environment that feels exclusive and unwelcoming. it is essential that our academic makerspaces are welcoming and that all students feel a sense of belonging and acceptance in these spaces. this project will use the flexible nature of an academic makerspace as the framework to provide students with the opportunity to connect socially in ways that have been shown to increase sense of belonging. this will be accomplished by integrating social engagement activities into a university affiliated makerspace. the engagement activities will be designed to support students' social and emotional development, which is an essential component to creating culturally competent, well-rounded engineers. due to the flexible and informal nature of the makerspace environment, it is an ideal place to build and create social connections between students. makerspaces provide a venue for informal learning and student connection that inspires

attributes associated with the professional formation of engineers: creativity, discovery, lifelong learning, teamwork, and critical thinking. this study will lay the foundation for future research that will inform strategies to create an equitable and inclusive makerspace culture with a focus on better supporting non-dominate students. this project aims to increase student sense of belonging in undergraduate engineering students through the integration of social engagement activities into an academic makerspace. the objectives of this project are to (1) strategically integrate social engagement activities that have been shown to contribute to increased sense of belonging and student persistence into an academic makerspace; (2) research the effects of the social engagement activities on student sense of belonging; and (3) increase engineering education research capacity at western washington university. the outcomes of this work will lead to identification of best practices for improving student sense of belonging in a makerspace environment. this research will investigate the impact of carefully designed social engagement activities on development of student sense of belonging. within the recent context of the covid-19 pandemic, social support and positive sense of belonging have been shown to counter the adverse social emotional effects of the experience. engagement activities will focus on supporting student social and emotional development, providing peer support, and building awareness of the importance of equity, inclusion, and **\*\*diversity\*\*** in engineering. the activities will be designed so that any student can participate regardless of ability level, time availability, or physical location. the research questions that will guide this work are (1) to what extent do students participate in the engagement activities within the makerspace and in which formats, and does this level of engagement vary based on student demographics? and (2) to what extent does participation in the engagement activities lead to an increased sense of belonging? these research questions will be investigated through a communities of practice theoretical framework using a two-year mixed methods research that includes survey development, analysis, student reflections, and focus groups. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: MRA: Distributions of Macrofungi: Quantifying Ecosystem and Climate Drivers of Fungal Reproduction

Awardee: University of New Hampshire

Amount: \$150,235.00

Abstract: fungi are essential components of terrestrial ecosystems worldwide. many fungi produce fruiting bodies in the form of mushrooms. these mushroom-forming fungi are key to forest nutrient cycling and, in association with plants, range from beneficial symbionts to pathogens. yet, we know very little about how regional, landscape, and local factors such as fire combine to affect the distributions of mushroom-forming species, nor how such distributions may be changing with a shifting climate. understanding mushroom distributions is particularly challenging because these fungi spend most of their lives as branching filaments of asexual cells (hyphae) below the soil, and their presence only becomes known if and when they produce a mushroom. recent work has shown that some fungi may occur as hyphae inside plants thousands of kilometers outside their known ranges, which are based on their sexual reproduction (i.e., mushrooms). these extended ranges of fungal hyphae suggest that different factors drive the distributions of life stages of these fungi, complicating efforts to forecast how fungi will respond to changing environments. this research will examine the distributions of mushroom-forming fungi across the united states by combining mushroom collections with sampling of fungal dna in soils, litter, plant tissues, and the air, at study locations in eight different states (ak, az, co, fl, ks, nh, mn, or). information at each site such as climate, plant communities, fire and soils will then be used to determine the conditions under which particular fungi are able to sexually reproduce and where they can only live as hyphae. the project will connect scientists with more than a thousand community members from mushroom clubs, local schools, and museums who will be involved in collecting mushrooms and working with fungal dna for scientific purposes. using the extensive climatic and geographic scope of the study, containing

diverse plant communities and fire disturbances, we will test how environmental variables at multiple scales influence distributions of sexual and asexual stages of fungi. we will also determine whether occurrence of a fungus in one stage (e.g., mushrooms) is predictive of its occurrence in other substrates at a site (e.g., soils, air, or plant tissues), allowing improved sampling schemes for fungi. together, this study will build the most complete picture to date of how macrofungal communities and their relationships change across climate gradients, thus building capacity to predict changes in fungal distributions and ecosystem processes under changing climate. further, unprecedented fires in recent years have placed fire ecology in the public eye like never before, such that expanding understanding of fire as a driver of cryptic aspects of bio\*\*diversity\*\* and ecosystem dynamics is timely and of broad interest. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: SRS RN: Sustainable Transportation Electrification for an Equitable and Resilient Society (STEERS)

Awardee: Texas A&M Engineering Experiment Station

Amount: \$150,000.00

Abstract: the us is in the midst of a massive transformation as both the electric grid becomes much more renewable and transportation becomes much more electrified, a change that will touch just about everyone. this nsf project goals are to ensure that this change is done in a way that is fair and technically sound, considering the need and well-being of all, done in a way that ultimately provides a more resilient and equitable society. the project is transformative by bringing together a broad team of researchers from four universities, coupled with a diverse group of outside advisors, to focus on sustainable transportation electrification in texas, a state that is extremely diverse and has its own electric grid. the goals will be achieved by utilizing the team?s broad expertise in the many

different areas needed to ensure success. the intellectual merits include fostering a culture of **\*\*diversity\*\*** and inclusion, developing criteria for success, developing the required research and education agenda, and doing pilot studies. the broader impacts of the project include helping to guide the equitable, sustainable and resilient electrification of transportation by engaging with a wide variety of partners, including government, community organizations and the business community. the purpose of this project is to develop a convergent team and associated proposal focused on the sustainable, equitable and resilient electrification of transportation. this is needed because society is beginning a massive transformation as the electric grid becomes much more renewable and as transportation becomes much more electrified. the convergent work proposed here is to ensure that this transformation is done so as to benefit all members of society. the specific focus is the supra-aggregation associated with the connected urban-rural systems in the electric grid covering most of the state of texas, with results applicable to the rest of the country. the team has broad expertise in the many required areas including the electric grid, renewable generation, transportation, urban studies, community planning, sociology, risk analysis, large-scale computing and data analytics, demographics, and education. the portfolio of research and education will be broad, leveraging the strengths of the convergent team with key aspects including developing better modeling and simulation, developing theories of change and more generalization theories, broad stakeholder participation, and equity with the goal of advancing knowledge. the effort has a strong focus on education to all, and should result in overall societal benefit given its broad focus on the electric and transportation infrastructures. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: SRS-RN: Planning for a Network to Address Pressures, Responses and Sustainability Intersections across a Growing, Innovative, and Dry State

Awardee: Colorado State University

Amount: \$150,000.00

Abstract: colorado, like many dry states in the western u.s., faces significant sustainability challenges from population growth, technological innovation, climate change, and competing development preferences and priorities. these challenges span the connected urban and rural areas within the region. while many researchers, practitioners, and communities in colorado are working to understand and address these challenges, efforts are fragmented. solving regional sustainability challenges requires an approach that understands regions as nested layers of natural, built, social, public, and government networks. the aim of this planning grant is to improve the ability to share knowledge, resources, and data across the public, private, and non-profit sectors in all phases of the research, leading to a more sustainable and regional system in colorado. a strong, connected, and coordinated cross-sector (university, government, industry, non-profit), and transdisciplinary network is needed to improve the capacity of groups already working on sustainability challenges in colorado. during the twelve-month planning period, the network will use a survey instrument to better understand the connectivity, collaboration, **\*\*diversity\*\***, inclusivity, perceived opportunities, barriers, and the range of sustainability work being done across colorado in the existing network. the second step will be to host workshops focused on understanding past and current sustainability activities, identifying which pressures are most important to different communities, and how these issues define relationships at various spatial scales. the cross-sector, interdisciplinary workshops aims to 1) expand existing network ties to include additional communities and minority serving institutions; 2) build knowledge and trust across diverse stakeholders; and 3) formulate a set of research objectives, methods, and scope for the development of a track 1 sustainable regional systems research networks (srs-rn) proposal. finally, researchers will conduct network and economic analyses designed to assess broad inequalities in resources and connections across the state to better understand barriers and inequities across various communities. network analyses will also examine how connections across disciplines, or lack thereof, are impeding development of a

transdisciplinary research agenda the workshops and analyses will focus scientific researchers and communities in conversations meant to identify the necessary social and technical platforms needed to break through these barriers, and to strengthen and empower the network. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: BPC-A: LEAP Alliance: Diversifying Future Leadership in the Professoriate

Awardee: Georgia Tech Research Corporation

Amount: \$150,000.00

Abstract: only 5.3% of the faculty at phd-granting universities are from the following underrepresented communities: black or african-american, hispanic, or american indian/alaska native. diversifying the computing professoriate is critical for providing excellent role models, shaping departmental programs and policies, and bringing diverse perspectives into research projects and programs. the leap alliance aims to increase the **\*\*diversity\*\*** of leadership in the computing professoriate by intentionally bringing together four cohorts of universities, each with common strengths and a common agenda. this work builds upon the lessons learned from a first cohort comprised of institutions producing a large percentage of computing faculty and adds three additional cohorts to further strengthen the pipeline to the computing professoriate. the goal of the leap alliance is to address the broadening participation challenge of increasing the **\*\*diversity\*\*** of the future leadership in the computing professoriate at research universities as a way to increase **\*\*diversity\*\*** across the field. key national leadership roles, such as serving on national committees that impact the field of computing, often come from research universities, making these institutions a critical point of focus. the alliance has previously piloted this effort in an initial cohort of 11 research universities who were found to produce over 50% of the faculty at the top 55 research institutions.

they will continue to bring together similar institutions in a second cohort, as well as cohorts that focus on institutions graduate a large percentage of computing phds and computing undergraduates, respectively. ultimately, the alliance aims to increase the **\*\*diversity\*\*** of phd graduates from the institutions that are the top producers of computing faculty, increase the exposure of academic careers at the institutions that already have good **\*\*diversity\*\*** in their phd graduates, and increase the retention of diverse undergraduate students at the institutions who send students to graduate school that go on to be faculty. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: SCC-PG : Human-AI Teaming for Flood Evacuation Decision Making

Awardee: Clemson University

Amount: \$150,000.00

Abstract: evacuation of coastal communities, particularly in rural areas, can be a challenge due to the topography, dispersed residential and population patterns, and limited number of roadways that lead further inland. this smart and connected community planning project will assess the viability of leveraging human knowledge and social media data with an artificial intelligence (ai) system to create a human-ai teaming (hat) paradigm addressing flood evacuation decision making in isolated coastal rural communities. in the process of creating a hat paradigm, we will integrate transportation network data with river information as well as volunteers' observations and social media data to leverage the strengths of local members of a community emergency response team (cert) with ai. this planning project advances the field by conducting a feasibility study of this hat decision-making tool, which will be tested through real-world flood evacuation examples in charleston, berkeley, and dorchester counties located in the lowcountry region of south carolina (sc). additionally, we will determine the barriers and motivations for understanding the usability of the researched hat

decision-making tool using qualitative (interview) protocols. this project supports education and **\*\*diversity\*\*** by providing research experiences to diverse students, as well as focusing on vulnerable, rural communities. additionally, this planning project supports nsf's mission to promote the progress of science and to advance the nation's health, prosperity, and welfare by seeking to (i) enhance flood evacuation by automatic data-driven decision making and (ii) identify potential barriers to the adoption of technology in rural volunteer communities. this research will co-create and implement a pilot solution for flood evacuation decision making by including systems thinking, human-machine engagement, human development training, and ai-driven decision making. the focus is on the advancement of flood evacuation techniques by transferring the traditional determination techniques (the expert evaluation approach) toward new and coherent hat computing. by leveraging hat protocols and applying them to a flood evacuation decision-making tool, our project has the potential to be transformative. tackling these issues will enable us to harness the full potential of ai as a partner in emergency management and response. this planning project brings together researchers from water resources engineering, social sciences and communication, transportation engineering, disaster science, computer science, and numerous volunteers and stakeholders to co-create solutions, build/strengthen collaboration with key stakeholders and cert organizations and identify potential barriers to technology use in rural communities challenged by a higher incidence of flood hazards and substandard infrastructure. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: SCC-PG: Preparing the Next-Generation Rural Workforce Through Inclusive and Place-Based Smart and Connected STEM Educational Delivery Models

Awardee: Iowa State University

Amount: \$150,000.00

Abstract: contrary to trends in most rural communities, which are shrinking and aging, many rural midwestern communities have experienced rapid population growth since the 1980s, as migrants and refugees have been moving there to meet growing labor demand in the agroindustrial sector such as meat and poultry processing. the school-aged residents of these growing midwestern communities, who are primarily the u.s.-born children of low-skilled workers, represent a significant untapped population of future stem workers and entrepreneurs who are growing up in, and want to stay in, rural america. there is a lack of research on workforce development in rural communities with large migrant and refugee populations. thus, there is a critical need to study strategies to both train, and also keep, this skilled workforce local to rural communities where expanded employment opportunities (e.g., industries building state-of-the-art factories) can limit out-migration of technical and entrepreneurial talent. the goal of this planning grant is to pilot new extended reality (xr)-enabled stem educational delivery models developed in collaboration with youth and adults in rural communities with large numbers of low-skilled workers. xr-enabled solutions can support active and experiential learning by enhancing hands-on activities, creating simulations of objects and experiences that may not be accessible in the physical world, and promoting learners' engagement with complex real-life problems. the planning research consists of three main activities: 1) identify stakeholder needs and aspirations for new place-based educational curricula in stem fields and entrepreneurship in partnership with the storm lake community via workshops, interviews, and focus groups; 2) use workshops to co-design (designing with as opposed to designing for) innovative xr-enabled technology delivery models to meet these needs; and 3) assess the outcomes of the pilot project via surveys. these activities will help address two research questions: 1) how can inclusive and place-based educational delivery models for rural workforce development benefit communities with large numbers of low-skilled workers? 2) which xr-enabled smart and connected technology solutions will improve inclusive and place-based stem educational delivery models in a rural community with a large number of low-skilled workers? this project is a partnership between iowa state university, iowa 4-h youth development, and the storm lake community school district. the city

of storm lake (pop. 10,600) was chosen as the site for these pilot activities because it is a rural iowa community with a large low-skilled workforce employed in the agroindustrial sector and a k-12 student population that is 64% english language learners and 85% students of color. the results of the planning grant will yield new insights into the educational needs of rural communities, and the opportunities and barriers that place-based technologies can offer for supporting those educational needs, which is an underexplored area in the literature. thus, this work is aligned with the smart and connected communities program, which endeavors to integrate community stakeholders into smart and connected community projects to co-create and pilot solutions that are directly informed by the needs, challenges, and opportunities of present and future communities. this project is also being funded via the nsf improving undergraduate stem education program, which seeks to support projects that have high potential for broader societal impacts, including improved **\*\*diversity\*\*** of students and instructors participating in stem education, professional development for instructors to ensure adoption of new and effective pedagogical techniques that meet the changing needs of students, and projects that promote institutional partnerships for collaborative research and development. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: FET: Medium: Robust Quantum Networks via Efficient Entanglement Distribution

Awardee: Duke University

Amount: \$150,000.00

Abstract: quantum computing has the potential, if realized, to significantly alter the computing landscape. however, building large-scale quantum computers is a key challenge. quantum networks (qns) enable the construction of large, robust, and more capable quantum-computing platforms by connecting smaller quantum computers. networked quantum systems have the potential to

significantly alter various activities in society by leading to faster development in medicine and engineering; more secure and privacy-preserving communication; and hitherto infeasible optimizations that leverage the immense computational power to identify efficiencies in manufacturing, logistics, finance, etc. this project is also using the potential and attractiveness of qns to design and offer a variety of educational programs, including a flexible post-baccalaureate program in quantum computing and networking to cater to non-traditional students, improve the **\*\*diversity\*\*** of undergraduate and graduate student body, and develop a quantum capable workforce.

building qns that support robust communication across nodes requires several fundamental scientific and technological advances, especially since classical techniques cannot be directly used in the quantum regime. qns can be used to build quantum computing systems that are more capable and more resilient than stand-alone quantum computers. this project is examining the design and implementation of qns from the ground up by developing an infrastructure for efficient communication and management of quantum entanglements in the network. in addition, the project is addressing specific challenges in two key applications of qns: (i) distributed quantum algorithms, and (ii) quantum sensor networks. the project is evaluating the developed techniques using large-scale simulations and over a 6-node qn testbed spread across long island, ny. the testbed is providing a high-fidelity platform to evaluate the effectiveness of our developed techniques. overall, the project has three research thrusts. in the first thrust, the project is developing an infrastructure to facilitate efficient communication and entanglement management. in particular, it is developing optimization techniques for (i) efficient generation of long-distance entanglement using multiple paths, and (ii) efficient distribution of pre-distributed entanglements. in addition, the project is developing efficient entanglement-distillation strategies in practical settings, and protocols for multicast primitives. in the second thrust, the project is addressing challenges in the context of two key qn applications to corroborate and validate the developed techniques. in particular, the project is developing optimization techniques for efficient distributed implementation of centralized quantum circuits; efficient distributed implementations are important for qn's computational success. in the

context of quantum sensor networks, it is designing efficient protocols for the estimation of binary parameter functions and investigating the benefit of entanglements in these settings. in the third thrust, the project is evaluating the above techniques using large-scale simulations and a small qn testbed. to evaluate qn performance effectively, the project is formulating novel performance metrics for qns; this requires non-trivial generalization of the classical network metrics. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Catalyst Project: Microbial trophic complexity in waterbodies: elucidating the role of algal-microbiome-nutrient interactions in harmful algal bloom formation

Awardee: Alabama State University

Amount: \$150,000.00

Abstract: catalyst projects provide support for historically black colleges and universities to work towards establishing the research capacity of faculty to strengthen science, technology, engineering, and mathematics undergraduate education and research. it is expected that the award will further the faculty member's research capability, improve research and teaching at the institution, and involve undergraduate students in research experiences. this project at alabama state university intends to investigate the role of microbial (bacteria, protists, algae) **diversity** and nutrient enrichment in the formation of harmful algal blooms (hab) in collaboration with researchers at auburn university. the project will contribute to efforts aimed at establishing an active research and training program in microbial ecology for educating and mentoring minority students. aquatic microbial **diversity** and trophic complexity represent a diverse set of prokaryotic and eukaryotic microbes. the role of aquatic microbes in reducing nutrient loads (via nutrient assimilation or cycling) and controlling other invasive or harmful microbial species such as microcystis spp., is acknowledged, though less explored. this project will mechanistically test the role of nutrient inputs and microbial **diversity** in the survival of microcystis spp., and hab formation in lab and field experiments using multi-omics approaches. the results from this project may contribute to a broader understanding of microbial factors underlying hab formation and control in waterbodies. overall, the proposed research may help us develop strategies aimed at predicting and controlling habs in the context of microbiome **diversity** and ecosystem functioning research. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: SRS RN: Convergent Innovations in Regional CirCULAR Economies (CIRCULAR)

Awardee: University of Illinois at Chicago

Amount: \$149,994.00

Abstract: a research network organized around the goal of creating and implementing circular economy solutions could address growing social, economic, and environmental impacts facing regional systems. using a case study based upon the city of chicago and its surrounding urban-rural linkages, research network planning will explore the underlying system structures and interactions that give rise to unsustainable resource consumption and waste generation. the planning will also identify potential solutions grounded in the emerging field of circular economy. the planning team will engage interdisciplinary researchers and non-academic partners in a process to co-create a research agenda for transforming regional systems towards circular economy. the group also will explore convergent research mechanisms for the deep integration of knowledge, methods, tools, and expertise from diverse perspectives that can advance the study of regional circular economies. finally, the team will devise a collaborative platform on which the scientific community and key stakeholders can share knowledge, translate findings, and enhance **\*\*diversity\*\*** and engagement. a planning activity will be undertaken to analyze how different actors in a regional circular economy affect the stocks, flows, depletion and regeneration of various types of capital, and how explicit identification of these flows might shape potential innovations. new thinking, technologies, and business models will be explored to tackle the circular economy challenge from the front end of the supply chain by re-designing products and developing resource sharing models and from the back end by closing material loops. the creation of circular economy business opportunities, especially in marginalized urban and rural communities, will be addressed through convergent approaches encompassing multi-capital flows, data science, and public policies with participatory co-design methods. this approach elevates the knowledge and experiences of diverse participants to that of subject matter experts so that any innovations developed will result in resource conservation and will meet community needs. the team's community partners are leaders in developing and implementing

new models that seek to broaden the influence of circular economy-based solutions. throughout the efforts of this planning activity, the importance of justice, equity, **\*\*diversity\*\*** and inclusion to the project's framing of circular economy will be emphasized. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: EAGER: Lip Reading by Unobtrusive Multimodal Sensors and Machine Learning Algorithms

Awardee: SUNY at Stony Brook

Amount: \$149,878.00

Abstract: the project aims to build an unobtrusive system to enable lip reading for patients with amyotrophic lateral sclerosis (als, also known as lou gehrig's diseases) and individuals with speech and hearing disorders. although there is rich literature on lip reading, the bulkiness, obtrusiveness, and/or immobility of these solutions impedes their applications in daily practice, especially for patients with neuromuscular disorders. there is an urgent need to develop novel lip-reading technologies to improve the communication capabilities of als patients with loved ones and healthcare providers. the proposed system can considerably improve on existing solutions for tracking and interpreting facial movements and more broadly, body movements, such as finger motions and body gestures. the ability to gather multimodal motion patterns from unobtrusive

sensors and apply machine learning (ml) to interpret the acquired data would greatly facilitate diagnosis, treatment, and rehabilitation of motion-related disorders, such as stroke and parkinson's disease. in addition, this work paves the way for the development of nonverbal communication interfaces enabled by facial/body gestures and opens new avenues for rehabilitation, robotics, and human-machine interfaces. this project presents an excellent opportunity for students to participate in cross-disciplinary research. part of the research will be integrated into the pi's courses and capstone design projects. the pis are committed to outreach activities and increasing the **\*\*diversity\*\*** through local minority organizations and the vertically integrated program at stony brook university.

the overarching goal of this project is to build an unobtrusive hardware-software platform for als patients that can capture speech-relevant lip gestures and decode lip movements for speech. first, a skin-like multimodal strain and electromyography (emg) sensing system will be designed to track both skin deformations and muscle activities associated with lip movements. self-assembled structures will be introduced to render the sensors ultrathin, breathable, and semi-transparent. second, the feasibility of converting the sensed lip signals to corresponding spoken words will be demonstrated. modern ml methods, and in particular, ensemble gaussian processes (gps) will be exploited for speech recognition. in the proposed scheme, each gp serves as a classifier and the final decision is made by fusing the results of all the gps by making use of methods within the bayesian framework. the potential contributions of the proposed work include: 1) design of skin-like strain and emg sensors with high sensitivity and good skin compatibility through a scalable self-assembly process. 2) integration of multimodal sensors for comprehensive in-vivo quantification of lip movements associated with speech. 3) development of ml algorithms that precisely convert lip movements to speech. 4) laying the grounds for developing a truly natural and unobtrusive hardware-software system for lip reading. our proposed work can fill the gaps in the existing solutions by an intuitive and unobtrusive technology for lip reading.

this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: EAGER: High-throughput discovery of microbial genes conferring improved root colonization.

Awardee: North Carolina State University

Amount: \$149,858.00

Abstract: plant roots are surrounded by billions of microscopic organisms called bacteria. these bacteria help the plant obtain nutrients and grow. because of how important bacteria are, many people are interested in developing fertilizers containing bacteria to help plants grow better. however, it has become clear that while some bacteria, when added to a growing plant, can help them grow under artificial laboratory conditions, hardly any bacteria can help a plant grow when applied under realistic conditions. we would like to understand why some bacteria are able to help plants grow, while some bacteria cannot. to do this, we will study the genes that growth-promoting

bacteria have, and determine whether these genes can convert a non-growth-promoting bacteria into a growth-promoting one. this work will be performed in corn, and will train one graduate student. beneficial microorganisms can greatly improve crop plant performance, motivating their use as seed inoculants. however, exogenous microbes are often outcompeted in the field, which limits their utility and reveals fundamental gaps in our understanding of root colonization. the rationale for this proposal is that the genes that are most important for colonizing the root are largely unknown. recent work using comparative genomics and knockout mutants has provided the first insights into the genes involved in root colonization. however, a complete picture of colonization must include how to enhance it, an understanding that is not currently available. since root colonization is multifaceted (encompassing interactions with other microbes, the host, and abiotic soil conditions) it is expected that a **\*\*diversity\*\*** of microbial and plant genes will impact root colonization. to parse this complexity, we will use a functional metagenomics approach to screen for genes conferring improved colonization maize under three different nutrient conditions. this work will therefore advance our understanding of root colonization and our ability to identify microbes that exert beneficial effects for prolonged periods. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: FW-HTF-P: Office Work in the AI Age

Awardee: University of Iowa

Amount: \$149,675.00

Abstract: office work is an important part of the american workplace across sectors, involving tens of millions of workers. further, doing office work is not just about the processing of paperwork and information; it also involves organizational knowledge, communication and relationship building, and other interpersonal skills. these twin issues of job reliance and job complexity raise concerns for the

design of artificial intelligence-based office automation tools that use software agents, machine learning, and data analytics. many such tools are designed without workers' needs or organizational complexity in mind; mistakes here can lead to reduced quality of life and job loss for workers, and worse outcomes for firms and customers. this planning project will develop a multi-disciplinary research agenda toward the careful scientific study of both office work and the design of automation that affects it, with the goal of improving both office automation and training and outcomes for workers. the project involves three main activities. the first is a comprehensive literature review using a combination of the critical review method, the systematized review framework, and a review of state-of-the-art office automation systems. the second involves qualitative analysis of a series of focus groups conducted with a broad sample of office workers about their daily work practices and challenges, their professional development and training, and their perceptions about the future of their job and of office automation. the third main activity is a three-day ideation workshop that will build on the findings from the first two activities. the research team will convene multidisciplinary academic and industry experts from human factors, computer science and artificial intelligence, economics, labor and human resource management, public policy, and equity and **\*\*diversity\*\*** to identify domains of office work and research themes that look most interesting, promising, and impactful for future research. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: LTREB Renewal: Long-Term Dynamics of Amphibian Populations Following Disease-Driven Declines

Awardee: University of California-Berkeley

Amount: \$149,431.00

Abstract: this project will examine the processes of invasion of a novel pathogen into a population for the case of a fungal pathogen that causes the disease chytridiomycosis in frogs and salamanders. outbreaks of emerging infectious diseases are increasingly recognized as major threats, not just to human populations but also to wildlife, and they increasingly threaten global bio\*\*diversity\*\*. the initial invasion of a novel pathogen into a susceptible host population can cause a disease outbreak resulting in high levels of mortality and declines in population size. when this happens, natural selection can occur for both the host and pathogen populations resulting in evolutionary changes in the host's susceptibility and tolerance to infection by the pathogen and the pathogen's ability to damage the host (virulence). these changes can in turn determine whether the host population can persist and recover from the disease. understanding these evolutionary processes is crucial in development of conservation strategies for threatened species. chytridiomycosis has had catastrophic effects on amphibians worldwide, and has been linked to numerous species extinctions in recent decades and many more species at risk. the researchers will investigate the patterns of evolutionary change in both the pathogen and the host (mountain yellow-legged frogs), following the invasion of the disease into hundreds of high elevation lakes in the california sierra nevada. this project will contribute to the understanding of the role of infectious diseases, such as chytridiomycosis, as agents of evolutionary change in natural populations. it will provide critical information to state and federal agencies, facilitating endangered species recovery and will train and educate undergraduates, graduate students, and the general public. this research builds on data from a long-term study of the population dynamics of mountain yellow-legged frogs (*rana sierrae* and *rana muscosa*) in the complex landscape of the california sierra nevada, and the affects of *batrachochytrium dendrobatidis* (bd) as it has invaded and spread through hundreds of frog populations. in most cases, invasion of bd results in outbreaks of the disease chytridiomycosis, rapid frog population declines, and local extinctions. in some cases, long-term persistence of frog populations occurs with bd in an enzootic state in which the impact of

the pathogen is greatly reduced. the research will extend and leverage 25 years of host population and disease data and archived genetic samples from *r. sierrae*/*r. muscosa* and *bd*. these resources will provide insight into how populations of both host and pathogen change during the transition from pre-pathogen arrival, to disease outbreak, to enzootic disease, to potential recovery of the pre-disease host population abundances. this dataset will be used to investigate the genetic basis for differences in host resistance/tolerance and pathogen virulence. cutting-edge genomic analysis of existing frog and fungal samples will complement laboratory experiments on *bd* virulence and frog susceptibility using *bd* cultures and frog mucosal samples from wild host populations. continued surveys of wild host populations will identify new disease outbreaks and describe the transition from initial outbreak to persistent enzootic state. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: IRES Track II: Rivers of the Andes Field Training

Awardee: University of Montana

Amount: \$145,456.00

Abstract: this project will train students in interdisciplinary, international river sciences and prepare them for the stem workforce, for their research, and for applying river science toward developing sustainable solutions to the human-induced stresses on rivers in the andes and globally. the proposed 12-day advanced studies institute will immerse 14 us-based graduate students in innovative field training in hydrology, geomorphology, and ecology for, in each of two years. working in the magdalena river basin, colombia, students will learn cutting-edge field, remote sensing, and computational tools, develop critical and systems thinking, and complete team-based research projects. students will work with instructors from university of montana, university of colorado, and colombia, taking advantage of long-term research sites in the magdalena river basin and broad

expertise. the rivers of the andes field training course will recruit a diverse group of students that broadens participation in sciences, and course materials and lessons learned will be shared openly and widely. river systems are under stress from climate change and growing demands for water, energy, and food. there is a strong disconnect, however, between where research and teaching about fluvial processes is concentrated, and where stresses on river systems such as new dam construction and associated impacts on humans and bio\*\*diversity\*\* are more recently evolving, such as in the andes. moreover, innovative and interdisciplinary approaches are needed to address challenges such as those surrounding river systems and to prepare students for the 21st century workforce. to address these challenges, we propose rivers of the andes field training (raft), a course to be taught in colombia that will provide field-based training in river sciences. course content will focus on hydrology and fluvial geomorphology, especially river mechanics, floods, and sediment regimes, and complementary content in tropical fish ecology and basin-scale, cumulative-impact and decision-support analysis. raft will use the magdalena river and its tributaries as a field site to illustrate broader content about river processes and andean rivers. the course will augment field training with classroom teaching about fluvial processes and observational, measurement and modeling approaches for understanding river processes. raft will provide a transformative experience for graduate student participants by combining innovative approaches and technologies with evidence-based best practices to not only advance knowledge of river sciences and associated tools, but also to promote critical and systems thinking and observational, interdisciplinary, and teamwork skills. raft will include international and multicultural experience, interdisciplinary teaching on cutting-edge process knowledge and tools, training in cross-scale and systems thinking, team-based projects, and practice in science communication. participants will be equipped to tackle wicked problems at the nexus of water, energy, and food systems and to apply science toward sustainable solutions to the challenges surrounding rivers in the andes and in the anthropocene. this project is jointly funded by the nsf office of international science and engineering (oise) and the established program to stimulate competitive research (epscor). this award reflects nsf's statutory

mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: A Data-Driven Employer-Academia Partnership for Continual Computing Curricular Change

Awardee: University of Illinois at Urbana-Champaign

Amount: \$144,647.00

Abstract: this project aims to serve the national interest by improving the supply of well-prepared computer science professionals capable of addressing the needs of american employers in the public and private sectors. this project intends to build a national partnership between employers and academia to help identify and mitigate gaps between the competencies of computing graduates and the expectations of potential employers. the project will survey computer science educators and practitioners to develop a model that defines the competencies expected by potential employers. the project team then plans to test the model at three institutions of higher education in alabama ? the university of alabama, tuscaloosa, tuskegee university, and shelton state community college. finally, the project team intends to develop tools and methods for institutions to identify and implement competency-based educational approaches for computer science across the nation. the project plans to use three interconnected strands of evidence-based activities to institute transformational change in the involved communities. first, a national strand will engage u.s. faculty in developing competency-based curricula informed by industry practitioner feedback. second, a local pilot strand intends to create transformative curricular change based on student competencies using an evidence-based change model in the three alabama institutions. sociologists and computing faculty on the team will help to understand, predict, and reduce barriers to competency-based employment of computing graduates from marginalized communities in the heart of the impoverished alabama black belt. the unique perspective relative to **\*\*diversity\*\***, equity, and

inclusion needs should serve as a model for other computing departments. the third strand will develop competency-based surveys for practitioners and academics to identify and refine specific competencies that are hoped to drive continual curricular change. outcomes, including the change process, national workshops, and experiences from the local process will help with transferability in the computing education community. in addition to informing curricula, the project will provide valuable data for educational researchers to help close the gap between employers and higher education. finally, as the competency approach to curricular design is relatively new in computing and engineering disciplines, lessons from this project will have the potential to transform curricular review and design in other stem disciplines. the nsf iuse: ehr program supports research and development projects to improve the effectiveness of stem education for all students. through the institutional and community transformation track, the program supports efforts to transform and improve stem education across institutions of higher education and disciplinary communities. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: A Data-Driven Employer-Academia Partnership for Continual Computing Curricular Change

Awardee: Mississippi State University

Amount: \$142,587.00

Abstract: this project aims to serve the national interest by improving the supply of well-prepared computer science professionals capable of addressing the needs of american employers in the public and private sectors. this project intends to build a national partnership between employers and academia to help identify and mitigate gaps between the competencies of computing graduates and the expectations of potential employers. the project will survey computer science educators and practitioners to develop a model that defines the competencies expected by potential employers.

the project team then plans to test the model at three institutions of higher education in alabama ? the university of alabama, tuscaloosa, tuskegee university, and shelton state community college. finally, the project team intends to develop tools and methods for institutions to identify and implement competency-based educational approaches for computer science across the nation.

the project plans to use three interconnected strands of evidence-based activities to institute transformational change in the involved communities. first, a national strand will engage u.s. faculty in developing competency-based curricula informed by industry practitioner feedback. second, a local pilot strand intends to create transformative curricular change based on student competencies using an evidence-based change model in the three alabama institutions. sociologists and computing faculty on the team will help to understand, predict, and reduce barriers to competency-based employment of computing graduates from marginalized communities in the heart of the impoverished alabama black belt. the unique perspective relative to **\*\*diversity\*\***, equity, and inclusion needs should serve as a model for other computing departments. the third strand will develop competency-based surveys for practitioners and academics to identify and refine specific competencies that are hoped to drive continual curricular change. outcomes, including the change process, national workshops, and experiences from the local process will help with transferability in the computing education community. in addition to informing curricula, the project will provide valuable data for educational researchers to help close the gap between employers and higher education. finally, as the competency approach to curricular design is relatively new in computing and engineering disciplines, lessons from this project will have the potential to transform curricular review and design in other stem disciplines. the nsf iuse: ehr program supports research and development projects to improve the effectiveness of stem education for all students. through the institutional and community transformation track, the program supports efforts to transform and improve stem education across institutions of higher education and disciplinary communities. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: IRES: Tropical Research Experience in Ecological Science (TREES):  
Regeneration dynamics in a hyper-diverse tropical forest

Awardee: Yale University

Amount: \$142,309.00

Abstract: the number and severity of abnormal weather events, such as storms and droughts, have increased in recent decades all over the world. in the tropical forests of south america, two large drought events occurred in 2005 and 2010, and more will likely happen in the future. although most tropical forests have a regular and predictable dry season that lasts several months, those that lie in the northwestern corner of the amazon region do not. here, high rainfall occurs in every month of the year, and researchers think that these forests may be hit particularly hard by lower rainfall. no one knows if these trees have had any previous experience of drought conditions. if they do grow poorly or die when there is no rain, then the kinds of trees that make up these forests may be quite different in future, leading to changes in how the forest works, as well as in the availability of food for animals and resources for people. this international research experiences for students (ires) project will carry out experiments to look at how tree seedlings of this area respond to drought, and how drought affects the other animals that interact with trees. the award addresses a critical scientific challenge while building capacity and experience in field and lab techniques among u.s. graduate and undergraduate students. to this end, we will mentor six u.s. students every year during the spring semester before, and fall semester after, they embark on an overseas research experience in ecuador, working with long-term collaborators of pis queenborough and metz at pontificia universidad catolica del ecuador, as well as with ecuadorian students. masters? and undergraduate students from yale university will be paired with undergraduates from lewis & clark college, a primarily undergraduate institution, to develop and conduct ecological research in a remote field station in the amazon rain forest: yasuni national park. this project will address a key knowledge

gap in forest ecology and climate change science: how do aseasonal ever-wet tropical forests respond to drought and natural enemies? the answer has clear implications for theoretical ecology (how infrequent disturbance, i.e., drought, affects the dynamics and composition of diverse ecological communities), climate change ecology (how forest structure, composition and distribution will likely change in the future), and policy (whether tropical forests remain a net carbon sink, or switch to a net carbon source thereby accelerating climate change). tropical aseasonal ever-wet rain forests are characterized by high rainfall and no dry season, as well as high biological **diversity** and globally significant carbon stocks. however, anthropogenic climate change is predicted to lead to increases in the frequency and severity of droughts in south america. drought is expected to act synergistically with other abiotic and biotic factors such as the pests and pathogens that drive the negative density-dependence that helps maintain the high **diversity** found in the tropics. recent work has focused on the impacts of drought on tropical seasonal forests, yet virtually nothing is known about how pest and pathogen pressure varies with water availability in the aseasonal ever-wet tropics nor how increasing drying may change the structure and function of these forests. this project, therefore, will investigate the interaction between climate and natural enemies on the performance of trees in a hyper-diverse, aseasonal tropical rain forest in the northwestern amazon. specifically, the research team will use experiments to test the effect of variation in water availability on pest and pathogen attack on young seedlings and how these effects will likely alter the strength and direction of negative density dependence; this information will transform current theoretical understanding of how these two factors affect tree performance, **diversity**, and distributions. results will also provide key information on how these economically and ecologically valuable, yet largely unknown, forests will change in a future of increasing drought. the prime goal of this project is to build capacity and experience in field and lab techniques among u.s. graduate and undergraduate students. to this end, the pis will mentor six u.s. students every year during the spring semester before, and fall semester after, they embark on an overseas research experience in ecuador, working with long-term collaborators of pis queenborough and metz at pontificia

universidad catolica del ecuador, as well as with ecuadorian students. masters and undergraduate students from yale university will be paired with undergraduates from lewis & clark college, a primarily undergraduate institution, to develop and conduct ecological research in a remote field station in the amazon rain forest: yasuni national park. yasuni national park and the associated forest dynamics plot are unique scientific resources. exposing u.s. students to the incredible richness of the most diverse forest in the world is an inspiring and humbling experience. students will be involved in meaningful research that is directly contributing to a broad understanding of the fundamental mechanisms that structure ecosystems and communities. ensuring that students understand how such science is conducted and how they can contribute is essential for how future generations decide to manage the world they inherit. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Integrative ecological perspectives on extinction processes - a multi-proxy case study of Hispaniolan subfossil and extant rodents

Awardee: Pennsylvania State Univ University Park

Amount: \$140,941.00

Abstract: this project brings together researchers and educators specializing in genetics, anatomy, and ecology to explore the factors that led to the recent extinction of endemic rodents on hispaniola. hispaniolan rodents provide an exceptional case study for examining the triggers and timeline of island extinction events. bio\*\*diversity\*\* loss is a global concern, and over 70% of mammalian extinctions in the last 500 years have occurred on islands. the caribbean has suffered the greatest species loss of any region in the world. fossil data generated from this project have the potential to contribute to conservation policy by clarifying which factors most contributed to extinction events, and will be helpful for understanding the disappearance of species on other islands. this project will contribute to education by providing mentorship to young scientists at multiple levels, including caribbean and caribbean-american undergraduates and by developing teaching modules for k-12 students. finally, a database of extinct hispaniolan mammals will provide better public access to scientific information both in haiti and the usa. this project will use morphometrics, stable isotope ecology, and ancient dna to (1) identify the ecological relationships among hispaniola's extinct endemic rodents, (2) determine the timing of species loss, (3) resolve phylogenetic relationships

among extinct taxa, and (4) clarify extinction triggers. the research team will rely on previously collected fossil material from three paleontologically-rich caves on the tiburon peninsula in southwestern haiti. the data generated will allow a more nuanced understanding of the roles that human behavior, climate, and individual species characteristics (e.g., body size, habitat, genetic **diversity**) have played in extinctions on hispaniola. the data generated can be leveraged by conservation biologists to inform conservation policy aimed at preserving the remaining biological **diversity** on hispaniola and in island systems more generally. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Characterizing Inclusive Strategies that Retain Black Students in Computer Science to Graduation and Beyond

Awardee: Howard University

Amount: \$139,407.00

Abstract: this iuse project aims to serve the national interest by identifying factors that lead to the lack of **diversity** in computing professions. research has shown that the first two years of science, technology, engineering, and mathematics (stem) majors are often where students are lost in the pipeline. this project will identify factors that affect the retention and graduation of under-represented minority students in the computing major. the goals are to identify inclusive strategies for success in computing programs and investigate ways to increase the retention and post-graduation success of black students in computing. of particular interest are strategies that are transferable to different types of institutions and stem fields in general. this project features a collaboration between two historically black colleges/universities and a primarily white institution that will work together to understand the challenges facing each institution and the strengths each institution brings to addressing this problem. through detailed transcript analysis, this research will take an

asset-based approach, focusing on the strengths of students succeeding in the major. two cohorts of lower division (freshman and sophomore) black cs students from two historically black colleges/universities (hbcus) and one primarily white institution (pwi) will be studied to measure perceived societal impacts and their understanding of content through conceptual assessment instruments. a cohort of upper division students will be studied to measure the factors that led to their success using surveys, a content assessment, and interviews. using a mixed methods analysis approach, white students will be compared to black students at the research intensive pwi and then the principal investigators will compare black students at the pwi to black students at the two hbcus. the goal is to expand knowledge of inclusive teaching strategies and provide institutional awareness of factors that can go beyond recruiting urms to focus on retention in the major and student success post-graduation. the nsf iuse: ehr program supports research and development projects to improve the effectiveness of stem education for all students. through its engaged student learning track, the program supports the creation, exploration, and implementation of promising practices and tools. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: BCSER: Using Virtual Reality to Train Geo-Spatial Reasoning

Awardee: Juniata College

Amount: \$138,607.00

Abstract: spatial reasoning skills include the abilities to visualize, interpret, and manipulate information in two dimensions (2d) and three dimensions (3d). these skills predict students' persistence and success in stem fields and are recognized as crucial aspects of geoscience education. thus, teaching undergraduate students spatial reasoning skills is expected to enhance their retention in stem fields and ultimately increase the number and **\*\*diversity\*\*** of stem professionals nationally. this project will study the effects of virtual reality (vr) training on students' spatial reasoning in geoscience contexts and, in the process, develop the principal investigator's (pi's) stem education research expertise. the project is supported by nsf's ehr core research building capacity in stem education research (ecr bcser) program, which is designed to build individuals' capacity to carry out high quality fundamental stem education research in the core areas of stem learning and learning environments, broadening participation in stem fields, and stem workforce development. stem professionals tend to have strong spatial reasoning abilities, and spatial abilities in adolescence correlate with persistence in stem fields. decades of research indicate that these skills can be significantly improved with training, which presents an opportunity to improve student retention in stem fields. the specific objectives of the project are (1) to develop the pi's stem education research skills and expertise; and (2) to design, implement, and disseminate the findings from a pilot study of the efficacy of vr training modules at juniata college and the university of south carolina at columbia. the pilot study will measure geoscience students' spatial reasoning skills before and after participating in either a vr training module or a more traditional training activity. the pi will work with an advisory board to evaluate the success of the professional development activities and pilot research project. the research, associated presentations, and interaction with the advisory board will contribute to the growth of the geoscience education research community through numerous new collaborations and related projects, as well as stimulate interest in education research among students and faculty members at the pi's home campus. improved training in spatial reasoning also has the potential to promote broader participation, retention and inclusion in stem fields. this award reflects nsf's statutory mission and has been

deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: NSF Postdoctoral Fellowship in Biology FY 2021: Ecological drivers of chemosensory gene family evolution

Awardee: Quinteros, Kevin

Amount: \$138,000.00

Abstract: this action funds an nsf postdoctoral research fellowship in biology for fy 2021, broadening participation of groups under-represented in biology. the fellowship supports a research and training plan for the fellow that will increase the participation of groups underrepresented in biology. a principal difficulty in biology is understanding how complex traits in an organism diversify, since complex traits can serve numerous functions and are controlled by multiple genes. plants and insects are the two most diverse groups on earth and are important to multiple ecosystems. the ability to detect floral scents by insects affects many plant-insect interactions. this project will investigate the genetic evolution of insect smell (olfaction). this research will combine gene-level data with the knowledge of a panamanian insect communities and plant-insect associations. integrating these biological scales can help our understanding of how and why environmental and ecological variation generates and maintains variation in complex traits. the fellow will develop a science communication workshop to foster a collaborative mentoring environment between college students and scientists. insect chemosensory gene families on the antennae participate in the olfactory recognition of floral scents. this project will unravel ecological factors contributing to the genomic evolution of floral scent detection in the highly co-evolved symbiosis between figs (genus ficus) and fig wasps (superfamily chalcidoidea). by addressing three questions: (1) does pollinating and non-pollinating fig wasp attraction to the same fig host result in convergent evolutionary patterns at the genomic level? (2) is greater host breadth and attraction to a larger **\*\*diversity\*\*** of floral scents

associated with greater chemosensory gene family variation? (3) is a larger effective population size also associated with greater chemosensory gene family variation? to answer the aforementioned questions, the fellow will use next-generation sequencing to construct de novo genomic references. furthermore, the fellow will incorporate comparative genomics with fig wasp community composition, estimates of effective population size, and plant-host association. this project will provide opportunities for the fellow to gain new skills in genomics, de novo genome assembly, and wet lab techniques. the broader impacts of this project include the development of a grant writing and science communication workshops with the goals to (1) disseminate tips and information on grant writing, (2) foster a mentoring environment in which participants can share their research, and (3) help establish professional connections and mentoring relationships among participants. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: NSF Postdoctoral Fellowship in Biology FY 2021: Towards an integrative understanding of conspicuous signals: phenotype, genotype, and adaptive function of a selected trait

Awardee: Khalil, Sarah

Amount: \$138,000.00

Abstract: this action funds an nsf postdoctoral research fellowship in biology for fy 2020, broadening participation of groups under-represented in biology. the fellowship supports a research and training plan for the fellow that will increase the participation of groups underrepresented in biology. this project aims to broaden participation of groups underrepresented in biology in two ways: (1) by implementing a program that will directly increase the **diversity** of postdoctoral scientists and (2) by funding the fellow to engage in novel research in functional genomics. this research investigates how red-backed fairywrens, a small australian bird, produce their red feathers, and how this individual redness may affect male reproductive success. connecting how a signal is produced to the associated reproductive outcomes is a fundamental question in evolution, yet these components are often studied independently. this research will characterize how red feathers are produced by identifying the genes underlying red pigmentation and will use long-term breeding data to track the reproductive success of red-backed fairywren males that vary in plumage color. showy male traits have long captured the imagination of evolutionary biologists. however, insular approaches to studying these mechanisms can hinder an integrated understanding of these traits. the proposed research spans different levels of inquiry to investigate the evolution of the sexually-selected, red plumage in the red-backed fairywren (*malurus melanocephalus*). the fellow proposes to explore the proximate and ultimate mechanisms responsible for the production and maintenance of hue variation, which varies extensively across the species' range. the fellow will collect samples in australia and use genomic and transcriptomic tools to identify candidate loci associated with color production. in addition, this work will identify the direction and strength of selection on loci in response to the observed female preference for redder plumage. the fellow will leverage demographic data from two populations and use quantitative modeling to quantify the adaptive function of plumage and its relationship to reproductive success. the integration of an ecologically relevant trait that influences fitness with species-wide genomic data will prove critical in

understanding phenotypic evolution. the project's broader impacts are designed to close a gap for underrepresented minority scientists by developing a program to target and support graduate students from underrepresented backgrounds when they are at the critical career stage of applying to postdoctoral positions. the proposed research will further broaden **\*\*diversity\*\*** by providing opportunities for underrepresented minority students to gain research experience at the high school and undergraduate level. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: NSF Postdoctoral Fellowship in Biology FY 2021: Determining the functional and physiological tradeoffs of thermal plasticity on ectotherm hosts combatting a novel pathogen

Awardee: Claunch, Natalie M

Amount: \$138,000.00

Abstract: this action funds an nsf postdoctoral research fellowship in biology for fy 2021, integrative research investigating the rules of life governing interactions between genomes, environment and phenotypes. the fellowship supports research and training of the fellow that will contribute to the area of rules of life in innovative ways. the united states is home to the highest **\*\*diversity\*\*** of salamanders in the world, but these amphibians are at risk of contracting an invasive fungal pathogen (called batrachochytrium salamandrivorans, or bsal for short) that is responsible for local extinctions of salamanders in europe. this research investigates how environmental temperature affect different salamander species? ability to manipulate body temperature and metabolism to influence immune function and combat bsal. in addition to providing information about management of an emerging disease in salamanders, this project supports the development of salamander-focused education and outreach materials. the fellow will create and disseminate early education lesson plans, host draw-to-learn events, and create informational posters and brochures

on the **diversity** and ecology of salamanders, which will all be made free and available for public use. the fellow will gain training in mentorship of students underrepresented in stem fields and in laboratory and analytical techniques for application in disease ecology research. bsal infects salamanders? major respiratory organ (skin), presenting a clear trade-off between upregulating immune processes at high temperatures while simultaneously increasing demands for oxygen. through experimental infection trials of desmognathus salamanders with and without thermal gradients and integrated assessment of functional genomics, behavior, and physiology, this project will 1) reveal if interspecific differences in disease susceptibility and functional responses are exacerbated by thermal environments; 2) quantify the trade-offs and influence of thermal environment on physiological responses during infection; and 3) provide predictions of the adaptive value of thermal plasticity in limiting disease risk. in addition to training in functional genomics and infection trials, the fellow will gain training in niche modeling to project bsal susceptibility risk across the landscape using information about plethodontid salamander species? thermal preferences. the data generated by this project can later be applied to answer ecological and evolutionary questions in ectotherms such as how phylogeny and local environment influence thermal preferences and tolerance, or how within-species variation may influence the capacity to respond to thermal constraints imposed by climate change. the project supports the fellow?s training in development and subsequent evaluation of educational materials for broad segments of the public. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: NSF Postdoctoral Fellowship in Biology FY 2021: Macrophysiological patterns in the thermal and optical properties of ant cuticular structures

Awardee: Barrett, Meghan

Amount: \$138,000.00

Abstract: this action funds an nsf postdoctoral research fellowship in biology for fy 2021, broadening participation of groups underrepresented in biology. the fellowship supports a research and training plan for the fellow that will increase the participation of groups underrepresented in biology. the project seeks to understand the connection between the structure of ant hairs and cuticles and their thermal and optical properties in variable environmental conditions. variation in the thermal properties of ant cuticles and hairs may allow them to heat up in cool environments and stay cool in hot environments. patterns in thermal and optical properties will be analyzed across species along an elevational gradient in the chiricahua mountains in arizona, and within species across latitudinal gradients in north america (from canada to mexico). as the first survey of bio\*\*diversity\*\* in cuticular structures with unique thermal/optical properties, this project will inspire engineering applications for global thermal and energy challenges (solar energy capture, radiative cooling, biomimetic materials, etc.). the fellow will also develop curricular materials about thermal properties of living organisms to be used in high-need los angeles schools and published in peer-reviewed education journals as well as hosting culturally responsive mentoring and grant writing workshops for minoritized students at the host institutions and national conferences. the fellow will use scanning electron microscopy to analyze the microstructure of ant cuticles and hairs, using both existing museum collections of widespread north american ant species and specimens collected by the fellow along an elevational gradient at the southwestern research station in arizona. fourier-transform infrared thermography, reflectance spectrophotometry (from ultraviolet to mid-infrared), and finite element method modeling will be used to analyze the thermal and optical properties of ant cuticular structures. environmental data collected using local weather stations will be used to understand if solar radiation and temperature can predict the optical/thermal properties of ant cuticular structures. the research is integrated with an education plan aimed at increasing participation of underrepresented groups by 1) developing k-12 lesson plans in partnership with noyce scholars and master teacher fellows to be used in high-need los angeles schools, and 2) publishing these plans in peer-reviewed and open access education journals. in addition, the fellow will expand culturally responsive mentoring

programs for minoritized postdocs and students at california state university dominguez hills and university of southern california. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: NSF Postdoctoral Fellowship in Biology FY 2021: Integrating microbial dynamics into methane models for northern peatland and post-glacial lakes

Awardee: Kuhn, McKenzie Ann

Amount: \$138,000.00

Abstract: this action funds an nsf postdoctoral research fellowship in biology for fy 2021, integrative research investigating the rules of life governing interactions between genomes, environment and phenotypes. the fellowship supports research and training of the fellow that will contribute to the area of rules of life in innovative ways. northern lakes are important sources of the greenhouse gas, methane ( $\text{CH}_4$ ) into the atmosphere. methane emissions from lakes are expected to increase as the arctic warms, leading to the thaw of ground that has been frozen for hundreds to thousands of years (permafrost) and releasing organic material into lakes, where it can be consumed by microbes and transformed into methane. microbes are the key drivers of methane emissions from lakes. different microbes leave distinct "fingerprints," (isotopic signatures) on methane. these fingerprints are crucial components of global methane models and are used to trace methane in the atmosphere back to its source. however, little is known about which microbes live in northern lake sediments or how microbial activity (methane production) and related methane emissions and fingerprints will change with warming and permafrost thaw. this project will identify microbes present in lake sediments in northern sweden and measure how actively microbes produce methane under different thaw and temperature conditions. this research represents a crucial step towards improving global methane models, which predict annual emissions and help inform policy decisions. the fellow will

also strive to increase **diversity** in stem by mentoring undergraduate students in the field and engaging in k-12 educational activities in new hampshire and northern sweden. the fellow will measure ch4 emissions/signatures, abiotic conditions, and sample sediment from two lakes in northern sweden with contrasting permafrost conditions and potentially different ch4-producing microbes (methanogens). the fellow will analyze sediments for microbial composition (genes) and abundance using 16s rna gene amplicon sequencing. with sediment incubations, the fellow will assess the metabolic activity (phenotype expression) of methanogens under warming conditions using metatranscriptome sequencing. the fellow will leverage a library of metagenome-assembled genomes from environments in northern sweden to map metabolic pathway activity and target specific metabolic genes in methanogens. ultimately, the fellow will build a statistical ch4 model that links microbial dynamics to ch4 emissions and associated isotopic signatures. the fellow will develop mentoring, professional, and research skills through the nsf bii emerge project summer institute for early career researchers and will mentor students in the emerge research experience for undergraduates program. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: NSF Postdoctoral Fellowship in Biology FY 2021: Investigating evolutionary mechanisms that facilitate local adaptation via inversions in the Atlantic silverside

Awardee: rick, Jessica A

Amount: \$138,000.00

Abstract: this action funds an nsf postdoctoral research fellowship in biology for fy 2021, integrative research investigating the rules of life governing interactions between genomes, environment and phenotypes. the fellowship supports research and training of the fellow that will contribute to the area of rules of life in innovative ways. natural environments are often heterogeneous, with strong

spatial variation in conditions within a species' range. populations within a species gain an advantage by adapting to these differing environments, and such local adaptation can be facilitated by structural variation within an organism's genome. the fellow will investigate how structural genomic variation allows populations to adapt to their environments, as well as how these types of variation enable population divergence and speciation. this research is important to understanding the mechanisms involved in the origin and maintenance of bio\*\*diversity\*\*, and how species may adapt to changing climatic conditions. through this research, the fellow will also broaden participation in stem through mentoring undergraduate students in independent research projects, advocating for open science and reproducible research practices, and training early-career students in open science principles and tools. this research will integrate data from common garden experiments, genomic analyses, and evolutionary modeling to investigate how structural genomic variation?specifically, inversions?facilitate local adaptation in wild populations. it will use the large inversion regions associated with locally adapted phenotypes in the atlantic silverside (*menidia menidia*) as a model system. key outcomes of this project will include: (1) identifying regions within inversions associated with local adaptation phenotypes using a common garden framework; (2) a population-wide selection scan to determine whether differentiation is greatest at inversion breakpoints or at candidate loci within inversions; and (3) simulations to quantify the conditions within which recombination suppression within inversions is a viable evolutionary mechanism for maintaining local adaptation. to achieve these outcomes, atlantic silversides will be collected and raised in a common garden experiment, and phenotypic and whole genome data from these individuals will be collected for analyses. the fellow will additionally facilitate two workshops on the topic of reproducible research, with a focus on bioinformatic workflows, targeted at upper division undergraduate and early career graduate students from historically underrepresented backgrounds in stem fields. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: NSF Postdoctoral Fellowship in Biology FY 2021: Investigating evolutionary mechanisms that facilitate local adaptation via inversions in the Atlantic silverside

Awardee: Rick, Jessica A

Amount: \$138,000.00

Abstract: This action funds an NSF postdoctoral research fellowship in biology for FY 2021, integrative research investigating the rules of life governing interactions between genomes, environment and phenotypes. The fellowship supports research and training of the fellow that will contribute to the area of rules of life in innovative ways. Natural environments are often heterogeneous, with strong spatial variation in conditions within a species' range. Populations within a species gain an advantage by adapting to these differing environments, and such local adaptation can be facilitated by structural variation within an organism's genome. The fellow will investigate how structural genomic variation allows populations to adapt to their environments, as well as how these types of variation enable population divergence and speciation. This research is important to understanding the mechanisms involved in the origin and maintenance of biodiversity, and how species may adapt to changing climatic conditions. Through this research, the fellow will also broaden participation in STEM through mentoring undergraduate students in independent research projects, advocating for open science and reproducible research practices, and training early-career students in open science principles and tools. This research will integrate data from common garden experiments, genomic analyses, and evolutionary modeling to investigate how structural genomic variation specifically, inversions facilitate local adaptation in wild populations. It will use the large inversion regions associated with locally adapted phenotypes in the Atlantic silverside (*Menidia menidia*) as a model system. Key outcomes of this project will include: (1) identifying regions within inversions associated with local adaptation phenotypes using a common garden framework; (2) a population-wide selection scan to determine whether differentiation is greatest at inversion breakpoints or at candidate loci within inversions; and (3) simulations to quantify the conditions

within which recombination suppression within inversions is a viable evolutionary mechanism for maintaining local adaptation. to achieve these outcomes, atlantic silversides will be collected and raised in a common garden experiment, and phenotypic and whole genome data from these individuals will be collected for analyses. the fellow will additionally facilitate two workshops on the topic of reproducible research, with a focus on bioinformatic workflows, targeted at upper division undergraduate and early career graduate students from historically underrepresented backgrounds in stem fields. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: NSF Postdoctoral Fellowship in Biology FY 2021: An integrative investigation of host-parasite coevolution across heterogeneous environments

Awardee: Salter, Jessie Frances

Amount: \$138,000.00

Abstract: this action funds an nsf postdoctoral research fellowship in biology for fy 2021, integrative research investigating the rules of life governing interactions between genomes, environment and phenotypes. the fellowship supports research and training of the fellow that will contribute to the area of rules of life in innovative ways. host-parasite interactions provide a window into how environmental conditions shape traits of interest, which is a key process in evolution that generates biological **\*\*diversity\*\***. this research aims to understand these processes using the northern bobwhite quail (*colinus virginianus*, which display impressive geographic variation in feather color) and their parasitic feather lice as a model system. understanding how environmental change induces changes in traits provides insight into how species evolved and may respond to climate change. bobwhites are a commercially important game species that have experienced population declines of >70% over the past forty years. the interactions between bobwhites and their feather lice are poorly known; this research will provide insight into how feather lice impact bobwhite populations

and may contribute to conservation strategy for this species, which is actively managed in 25 states. to increase broader participation in science, the fellow will develop public exhibits and educational activities based on this research through the natural history museum of los angeles county. parasitism is the predominant life history strategy on earth, yet we have a limited understanding of how host-parasite interactions shape the coevolution of traits in wild populations. bobwhites and their feather lice are a tractable wild system for testing current evolutionary theory and developing new models of host-parasite coevolution across heterogeneous environments. the fellow will analyze phenotypic and ecological data, including parasite abundance, to assess whether feather lice are associated with plumage phenotypes in bobwhites. the fellow will quantify phenotypic and genetic data from lice collected from bobwhite specimens to assess the effects of plumage variation on the phenotypes and genotypes of coadapted lice. finally, the fellow will use cophylogenetic analyses and whole-genome sequence data from range-wide pairs of coadapted bobwhites and lice to test current theories of coevolution and identify regions of the genomes of both species that are under selection due to environmental variation and host-parasite interactions. through these activities, the fellow will support the mentorship and training of two students from underrepresented stem groups. additionally, this research will be conducted in a museum setting, and will develop and improve methods for collecting phenotypic and genomic data from museum specimens. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: NSF Postdoctoral Fellowship in Biology FY 2021: Integrating genetic-morphologic concepts of diversity in ecological and environmental context

Awardee: Trubovitz, Sarah

Amount: \$138,000.00

Abstract: this action funds an nsf postdoctoral research fellowship in biology for fy 2021, integrative

research investigating the rules of life governing interactions between genomes, environment and phenotypes. the fellowship supports research and training of the fellow that will contribute to the area of rules of life in innovative ways. currently, we have a limited understanding of how **diversity** is expressed in one of the largest and most critical ecosystems on the planet: marine plankton. this makes it difficult to predict the impacts of climate change and imminent **diversity** loss on key ecosystem functions that society relies on such as primary production and food web interactions between organisms. in order to understand plankton **diversity** and its importance, this project will investigate how **diversity** is expressed in an abundant group of marine protists, the polycystine radiolarians. research will center on the systematic integration of genetic, morphologic, and ecologic information to improve our knowledge of different scales of radiolarian **diversity** and its environmental context. to achieve broader participation, the fellow will mentor undergraduate students at the host institution, and engage the public in locally relevant marine science through outreach programs at the wrigley marine science center. recent surveys of molecular **diversity** have revealed over an order of magnitude more radiolarian species than morphology-based studies. poor harmonization between molecular and morphological taxonomy has made it impossible to pinpoint the reasons for this discrepancy, demanding a reevaluation of classic species concepts and molecular methods. to address this, the fellow will investigate relationships and differences between genetic and morphological concepts of **diversity**. radiolarian samples will be collected from multiple depths at station aloha (hawaii) and classified based on skeletal morphology as well as sequencing analysis of the v4 region of the 18s rna gene. patterns of genetic variation paired with observations of physical specimens and their ecological niche information will be used to determine how genetic **diversity** is expressed both morphologically and ecologically. environmental and biological metadata available for station aloha will be used to interpret the function of hierarchical levels of radiolarian **diversity** in environmental context. research products will include new radiolarian genetic barcodes, which will improve the accuracy of ongoing efforts to monitor global plankton **diversity** dynamics in a changing climate.

the fellow will undergo training in live plankton sampling and molecular analytical methods, as well as gain vital experience in academic mentoring and outreach. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: NSF Postdoctoral Fellowship in Biology FY 2021: Are variants under selection for disease resistance predictive of disease susceptibility across taxa?

Awardee: Sharo, Andrew George

Amount: \$138,000.00

Abstract: this action funds an nsf postdoctoral research fellowship in biology for fy 2021, integrative research investigating the rules of life governing interactions between genomes, environment and phenotypes. the fellowship supports research and training of the fellow that will contribute to the area of rules of life in innovative ways. since the 1970's, 3 billion birds have disappeared from north america. infectious disease is an important cause of bird mortality. beginning in 1999, west nile virus rapidly spread across north america, primarily infecting birds and sometimes leading to their death. over the past two decades, house sparrows have evolved resistance to west nile virus, but the mechanism is unknown. this project will identify the genetic mechanisms through which house sparrows have evolved resistance to west nile virus. birds are important vectors for many diseases, and this will be the first project to characterize how birds adapt to west nile virus. the fellow will use this information to predict whether other species of birds are susceptible to west nile virus. the fellow will recruit and train underrepresented minority students at uc santa cruz, a hispanic serving institute, to work on this project. the fellow will also volunteer outreach and teach to diverse undergraduate and k-12 students, inspiring them to pursue stem careers. this project will first generate rna-seq from house sparrows previously infected by west nile virus. these data will be used to identify candidate genes where expression or splicing is associated with west nile viral load. next,

the fellow will identify genetic variants that are under selection in wild house sparrow populations through dna-seq of museum specimens. specifically, the fellow will sequence samples from multiple house sparrow populations before and after the introduction of west nile virus and determine whether adaptation is parallel in response to west nile virus. by limiting our scope to the candidate genes identified previously, this project will identify variants that are likely to mediate west nile resistance. finally, the fellow will develop a west nile virus susceptibility predictor based on these variants and assess its ability to predict susceptibility across avian taxa. the fellow will be trained in state-of-the-art techniques to isolate dna from museum samples and will develop a strong understanding of disease ecology. the fellow will also lead sampling field trips of underrepresented minority students through caledna, a community science initiative to monitor ecological \*\*diversity\*\* through environmental dna. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: NSF Postdoctoral Fellowship in Biology FY 2021: Mechanisms and consequences of thermal stress effects on cognitive performance

Awardee: Proffitt, Melissa R

Amount: \$138,000.00

Abstract: this action funds an nsf postdoctoral research fellowship in biology for fy 2021, broadening participation of groups under-represented in biology. the fellowship supports a research and training plan for the fellow that will increase the participation of groups underrepresented in biology. the project will address the need to understand how organisms respond to rising temperatures by measuring the organism's behavior and physiology in response to temperature in two closely related songbirds. these songbirds vary in their ability to tolerate hot temperatures, which will allow the fellow to directly test this question. this research will advance scientific knowledge by providing

insight into how and why different populations of birds vary in their response to heat in a changing climate. the project benefits society by taking a 4-tiered approach to address the need to develop a sense of community to support the recruitment and retention of underrepresented groups at the postdoctoral level. many species are shifting their range in response to changes in climatic conditions that are altering selective pressures. behavior can buffer these effects and facilitate survival. cognitive traits, such as learning, can be particularly vital to survival when facing new challenges and could mean the difference between a species persisting and going extinct in an area. however, not much is known about how variation in thermal tolerance affects behavioral performance, particularly of cognitive traits. the project includes a set of integrative, experimental studies to fill this gap in knowledge by experimentally manipulating air temperature to quantify effects of learning on a spatial foraging task. critically, the approach uses individuals from multiple populations across a latitudinal gradient spanning the shifting range limit of two species of songbird who vary in thermal tolerance, to ask how variation in thermal tolerance affects variation in cognitive performance under thermal stress. overall, the research aims to use thermal stress as a biologically relevant tool to understand connections between behavioral responses to an organisms' environment and underlying physiological mechanisms over different scales from neurons to individuals to populations and species. the project will expand the evolutionary framework of the fellow's research program and her training in designing and analyzing behavioral assays. broadening participation activities focus on building community for postdocs from under-represented groups by organizing career development workshops, a lightning talk series, formalization of postdoctoral committees, and a postdoc run outreach event to provide an opportunity for the younger generation to see **\*\*diversity\*\*** in scientists. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: NSF Postdoctoral Fellowship in Biology FY 2021: Deciphering the epigenetic signatures associated with invasive capacity in mixed seagrass communities

Awardee: Chiquillo, Kelcie Lorena

Amount: \$138,000.00

Abstract: this action funds an nsf postdoctoral research fellowship in biology for fy 2021, broadening participation of groups under-represented in biology. the fellowship supports a research and training plan for the fellow that will increase the participation of groups underrepresented in biology. the proposed research addresses the great debate of whether nature (genetics) or nurture (environment) drive biological invasions, i.e., the process where introduced species become harmful, threatening bio\*\*diversity\*\* and natural ecosystems outside their normal range. it is known that nature and nurture work in conjunction to produce biological traits. traits are controlled by genes, and the expression of these genes (or how much these genes are turned on) will change depending on the environment that they are in. not all introduced species become invasive, and this research will help understand how environmental changes are linked to invasions for conservation biology. the outcomes of this research will be to determine which factors and habitat characteristics modify gene expression and promote invasion success. this is particularly important as invasive species can be global threats to local ecosystems, like seagrass meadows, which support a wide variety of life (e.g. fish, sea turtles, manatees and birds); thus, it can have implications on society by altering ecosystem services that people depend on. this project will provide high quality research opportunities to traditionally excluded groups, and indirectly help management in recovery of seagrass communities. the fellow will use both field work and epigenetic technologies to understand the function and modifications of anthropogenic stressors in seagrass meadows and determine what role epigenetic mechanisms play in biological invasions. the fellow will test the hypotheses of whether species interactions, epigenetics, and microbial communities induce the epigenetic signatures of the seagrass invasion and determine the physiological mechanisms that promote an invasive phenotype. for that purpose, this work will characterize epigenetic

modifications, microbial populations, and their interaction with energetic networks (e.g. nutrient acquisition) to promote induced competitive phenotypes linked to acclimatization. in doing so, the fellow will broaden participation by developing a culture-based support program called ?salti: science acceleration and learning techniques inclusivity? week, where nsf research experience for undergraduates students and their families learn hands-on approaches to conducting marine science in south florida. the proposed program will produce engaging science-communication films. by facilitating family support, the **\*\*diversity\*\*** of people who are engaged in science will strengthen, and they and others can gain a deeper understanding of its ecological importance and feel empowered to protect the marine environment. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: NSF Postdoctoral Fellowship in Biology FY 2021: Habitat suitability: ecocultural restoration in the Klamath Basin

Awardee: Yazzie, Kimberly

Amount: \$138,000.00

Abstract: this action funds an nsf postdoctoral research fellowship in biology for fy 2021, broadening participation of groups underrepresented in biology. the fellowship supports a research and training plan for the fellow that will increase the participation of groups underrepresented in biology, particularly karuk youth and indigenous students at the university of washington. the fellow will utilize habitat suitability models to characterize the abundance and distribution of cultural keystone species, willow and salmon, in response to ecocultural restoration and ecological disturbance. the project will assess the effects of indigenous fire stewardship on climate adaptation to understand how fire promotes diverse landscape values (e.g., cultural foods and basketry) and restores ecological function (e.g., stream temperature). this research will provide insight to ecological

resilience and ascertain the effects of disturbance on the landscape, including floods and fire. with the largest dam removal project in u.s. history slated to begin on the klamath river in 2023, this research is timely. the fellow will survey pre-dam removal conditions that tribes can use to prioritize and identify optimal pathways for ecocultural restoration across co-managed landscapes. the fellow will assess a habitat suitability model framework coupled with place-based science to characterize habitat loss and species **diversity** of cultural keystone species, plants and salmon, within selected habitat zones identified by the karuk tribe in the mid-klamath basin, california. spatially explicit data and known occurrences of focal species will be used in the model, including a combination of fine-scale and broad-scale ecologically relevant variables (e.g., topography, soils, geology, climate). the fellow will use geospatial methods, aerial imagery and drone footage to quantify standing forest composition. species occurrences will be confirmed with field surveys and independent test locations at different resolutions will determine local-scale model accuracy. the fellow will assess a) the utility of habitat suitability models to determine that ecocultural restoration activities, cultural burns, increase habitat **diversity** of focal species, and b) explore the influence of grain and extent in local to broad-scale model predictions of environmental suitability at different site locations. an intergenerational knowledge exchange, co-mentorship and community participation will enhance research interpretation and outcomes. the fellow will serve as a mentor to tribal youth through a summer internship program and co-develop research materials and publications from this research with the karuk tribe. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: NSF Postdoctoral Fellowship in Biology FY 2021: Oviposition-relevant gustatory receptor evolution as a missing link governing insect-host plant specialization

Awardee: Godfrey, Rebekah Keating

Amount: \$138,000.00

Abstract: this action funds an nsf postdoctoral research fellowship in biology for fy 2021, integrative research investigating the rules of life governing interactions between genomes, environment and phenotypes. the fellowship supports research and training of the fellow that will contribute to the area of rules of life in innovative ways. identifying a cohesive theory of insect-host plant associations has proved one of the most challenging biological questions. while the ecological and evolutionary relationships between insects and their host plants often hinge on variation in a few key genes, we know relatively little about which genes drive host plant associations and how variation in these genes affects host plant selection or use. where an insect lays her eggs has very real fitness consequences, making oviposition a strong candidate behavior to connect genetic variation and host plant use. this research will identify taste receptor genes involved specifically in oviposition and quantify variation in these genes within and across species of closely related hawkmoths that vary in host plant use. the fellow will work within the mcguire center for lepidoptera **\*\*diversity\*\*** to directly mentor scientists at the undergraduate and graduate level and to broaden knowledge of and interest in insect neuroscience both in students underrepresented in stem and the general public. this project tests the hypothesis that selection on oviposition-related sensory receptors acts as a primary driver in host breadth in lepidoptera. the project focuses on gustatory receptors (grs) because they are the primary sensory receptors used to sense plant surface compounds and elicit or deter oviposition. the fellow will (1) test whether variation in gustatory receptor genes is associated with host use in species that vary in host breadth, (2) identify gustatory receptor genes involved in host selection by comparing sex-specific gene expression, and (3) test whether variation in receptor gene sequences and gene expression across populations are associated with population-specific host use. this fellowship will provide the fellow with training in collecting and analyzing molecular data from an evolutionary perspective. furthermore, the project will provide functionally relevant targets for gene editing in future neuroethology experiments and will serve as a model for studying natural selection on the nervous system; the fellow's museum outreach activities and involvement of

students in research ensures these ideas and training will reach a diverse, public audience. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: NSF Postdoctoral Fellowship in Biology FY 2021: Identifying high-risk bioregions and predicting the impact of climate change on the distribution of genetic diversity

Awardee: Boria, Robert A

Amount: \$138,000.00

Abstract: this action funds an nsf postdoctoral research fellowship in biology for fy 2021, integrative research investigating the rules of life governing interactions between genomes, environment and phenotypes. the fellowship supports research and training of the fellow that will contribute to the area of rules of life in innovative ways. forecasting how bio\*\*diversity\*\* will change in the future due to natural and human impacts is a primary focus of both ecology and evolutionary biology. one factor important to the geographic distribution of \*\*diversity\*\* at multiple levels - genes, species, and morphology - is climate. this proposal will study how populations have responded to past climate change, and how these responses could influence future climate change responses. this research will generate maps of future genetic \*\*diversity\*\* to identify potential areas where climate change could have a significant impact on species \*\*diversity\*\*. understanding the spatial distributions of intraspecific genetic \*\*diversity\*\* and the role of climate refugia in evolutionary and ecological processes is important because it likely determines their potential for persistence in the face of future climate change. determining how the distribution of intraspecific \*\*diversity\*\* of north american taxa was directly influenced by climate and landscape changes may illuminate broad-scale patterns of species? responses to other climatic events, or more generally, to barriers impeding or constraining gene flow. this research will study how populations have responded to past climate change and how the historical distributions and past areas of climate refugia for four small mammals

will influence future climate change responses. this study will utilize an interdisciplinary approach ? three different data types and/or tools (next generation sequencing; gis; bioinformatics) ? to understand how historical events have shaped the current distribution of genetic \*\*diversity\*\* within a widespread species in north america and the impacts on future genetic \*\*diversity\*\*. to broaden participation, the fellow will recruit five high school students from underrepresented groups to help facilitate the research. the fellow will mentor them through their high school education and the college application process. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: NSF Postdoctoral Fellowship in Biology FY 2021: The buried solution for agricultural resilience: arbuscular mycorrhizal fungi

Awardee: Guzman, Aidee

Amount: \$138,000.00

Abstract: this action funds an nsf postdoctoral research fellowship in biology for fy 2021, broadening participation of groups under-represented in biology. the fellowship supports a research and training plan for the fellow that will increase the participation of groups underrepresented in biology. longer and more extreme drought periods pose a substantial challenge for agriculture globally. at the same time, the dominant farming model has dramatically reduced crop \*\*diversity\*\* leading to a decline in soil bio\*\*diversity\*\*, especially in an important group of fungi called arbuscular mycorrhizal fungi (amf). these organisms are known for alleviating plant drought stress. therefore, the goal of the proposed research is to (1) determine the mechanisms by which crop \*\*diversity\*\* and soil fungi are connected, and in turn, (2) understand the functional mechanisms by which plant-fungi interactions buffer crops against drought stress. this research will engage underrepresented students in the local rural communities and at the sponsoring institution. specifically, the fellow will develop a novel and

integrative approach to simultaneously support future stem educators in rural high schools and develop an experiential learning program for high school students in minority-majority rural communities in california's san joaquin valley. crop diversification has emerged as a strategy to harness the potential benefits of soil bio\*\*diversity\*\*, especially amf, to buffer crops against drought, a current and growing threat to agricultural productivity. however, while greater crop \*\*diversity\*\* can enrich amf communities, linking soil bio\*\*diversity\*\* to ecosystem functions in the contexts of agricultural systems remains a fundamental challenge. therefore, more studies are needed to understand how agricultural management may alter fungal community composition and select for fungal traits may or may not alleviate drought stress. this research seeks to fill this knowledge gap by using a novel approach that integrates soil fungal ecology, functional genomics, and plant ecophysiology to test whether crop diversification can positively alter the functional composition of fungi and plant-fungal interactions to alleviate drought stress. by comparing fields with varying levels of crop \*\*diversity\*\* (monoculture versus polyculture) and manipulating water availability, this research will examine the contribution of mycorrhizal fungi (versus non-mycorrhizal fungi) to crop productivity under drought directly in the field. the fellow will also develop an experiential learning program for rural minority-majority high schools to empower underrepresented high school students to pursue stem careers and support future stem educators in rural high schools. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Awardee: Patton, Austin H

Amount: \$138,000.00

Abstract: this action funds an nsf postdoctoral research fellowship in biology for fy 2021, integrative research investigating the rules of life governing interactions between genomes, environment and phenotypes. the fellowship supports research and training of the fellow that will contribute to the area of rules of life in innovative ways. how do new species arise? do they arise in isolation? or can hybridization, the exchange of genetic material between species, instead facilitate adaptation, and speed up the speciation process? recently, there has been growing support for the latter hypothesis but, to date, few studies have experimentally demonstrated that hybridization influences aspects of evolutionary fitness, such as survival, in vertebrate species. this project will address this by combining laboratory studies of feeding performance, fitness experiments in the field, and genetic sequencing of three species of bahamian pupfish. this research will provide insight into the capacity of hybridization to facilitate adaptation to climate-change associated environmental shifts. the fellow will expand participation by involving the bahamian community both in educational and collaborative opportunities, as well as by conducting outreach involving local public schools and community colleges within the bay area. can gene flow promote adaptive radiation? to address this question, the fellow will conduct a comprehensive field fitness experiment, integrating genomic, morphological, environmental, and feeding performance data. the fellow will also quantify the extent to which the visual environment modulates the phenotype-performance-fitness map. using 4,000 experimental hybrids and purebred species, the fellow will measure fitness in high- and low-turbidity lakes and

feeding performance of hundreds of these fish will be assessed in similar environments pre- and post-experiment. these data will be used to construct a genome-phenotype-performance-fitness map, demonstrate the functional consequences of adaptive introgression, and test the hypothesis that environment modulates the phenotype-performance-fitness map. with this experiment, the fellow will quantify the sensitivity of the relationship between morphology, performance, and fitness to a hurricane-induced environmental perturbation of lake turbidity. gaining this understanding is critical to predicting the sensitivity of san salvador island's micro-endemic pupfish **\*\*diversity\*\*** to increased hurricane activity in coming years. this research will provide the fellow with a **\*\*diversity\*\*** of training, from fish care to performance assays, field experiments, selection and genomic analyses. the fellow will establish a collaboration at the university of the bahamas, providing training to their students, and offer lessons on evolution to students at the san salvador island high school. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: NSF Postdoctoral Fellowship in Biology FY 2021: : Investigating how neopolyploidy affects the core microbiome and how the extended phenotype can facilitate ecological establishment

Awardee: Anneberg, Thomas

Amount: \$138,000.00

Abstract: this action funds an nsf postdoctoral research fellowship in biology for fy 2021, integrative research investigating the rules of life governing interactions between genomes, environment and phenotypes. the fellowship supports research and training of the fellow that will contribute to the area of rules of life in innovative ways. polyploidy, or whole-genome duplication, has frequently acted as a mechanism of generating new species. however, first-generation polyploids, or neopolyploids, are expected to suffer from a high risk of local extinction shortly after they arise due to competition with their diploid parents for limited space and resources. despite the expectation that

neopolyploids should go locally extinct shortly after they arise, we see a disproportionately high number of established polyploids in nature. this research will address this apparent gap in knowledge by investigating what factors can drive the establishment of neopolyploid populations. the project will specifically characterize how environmental resource supply and microbial interactions affect the ability of neopolyploids to persist in the presence of their diploid parents and become established. the goal of this research is to understand the ecological drivers of neopolyploid establishment by testing two hypotheses: that neopolyploid establishment is 1) dependent on the external environment, and 2) is facilitated by the extended phenotype: neopolyploid genotypes and their microbiomes. the approach to testing these hypotheses is to first characterize how neopolyploidy affects the microbiome community and shapes host phenotypes. second, to predict the outcome of competition between diploids and their neopolyploid descendants and whether it differs given the extended phenotype, multigenerational competition experiments will be combined with modern coexistence theory. the expected outcomes of this research are to understand 1) how neotetraploidy affects the microbiome composition and **diversity** and 2) how the microbiome affects the competitive ability of neotetraploids against their diploid ancestors, and 3) whether these patterns vary with the genotype of a lineage or across environmental resource gradients. the fellow will use diploid and synthetic neotetraploid duckweeds, which is a uniquely well-suited system for this research since they have rapid generation times and are compact enough to allow high replication across various environmental conditions. additionally, this research will incorporate the mentorship of high school and undergraduate students from under-represented groups to carry out independent research projects, as well as facilitating outreach activities with local intercity classrooms on ecological principles. " this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: NSF Postdoctoral Fellowship in Biology FY 2021: How does arbuscular mycorrhizal fungi impact pollination and plant fitness in an anthropogenically disturbed environment?

Awardee: Feters, Andrea Marie

Amount: \$138,000.00

Abstract: this action funds an nsf postdoctoral research fellowship in biology for fy 2021, integrative research investigating the rules of life governing interactions between genomes, environment, and phenotypes. the fellowship supports research and training of the fellow that will contribute to the area of rules of life in innovative ways. the research will focus on mutualistic interactions between plants, pollinators, and soil-dwelling arbuscular mycorrhizal fungi. the plant-pollinator mutualism may be altered decades after anthropogenic disturbances, like surface mining. plants growing in soils contaminated by mining may lack the resources needed to invest in floral traits attractive to pollinators. however, the presence of arbuscular mycorrhizal fungi could lessen the negative effects of soil contamination on attractive traits. interactions between the plant-arbuscular mycorrhizal fungi and plant-pollinator mutualisms in reclaimed surface mines remain largely unexplored. this research will illuminate how arbuscular mycorrhizal fungi promote attractive floral traits and pollinator visitation, which in turn contribute to plant persistence. the fellow will disseminate the outcomes in many venues, from national meetings to student-led science clubs at the ohio state university. additionally, the outcomes will be used to design guest lectures and a lab module with quantitative and active learning components for undergraduate biology courses; through the research, the fellow will mentor undergraduate students from underrepresented groups. given the extensive impacts of anthropogenic disturbances on natural environments, understanding the role that mutualists play in alleviating the negative effects of these disturbances is a key lesson for researchers and students of ecology alike. the research has two aims. the first is to characterize the arbuscular mycorrhizal fungal mutualists of ten plant species reflective of the plant **diversity** at the wilds, a conservation park with a history of surface mining in cumberland, ohio. the second aim is to determine: 1) whether arbuscular mycorrhizal fungi promote attractive floral traits of one of the focal plant species and

subsequently increase pollinator visitation and plant fitness and 2) whether the fungi mitigate the negative effect of anthropogenic disturbance on the plant-pollinator mutualism via the promotion of floral traits like phenology, color, scent, and nectar quantity. it is hypothesized that plants growing with arbuscular mycorrhizal fungi will have more attractive floral traits, higher pollinator visitation, and higher fitness such that the effect will be greatest when soil contamination is also present. in addition, the guest lectures and lab module will be planned with the best pedagogical practices for increasing equity and inclusion in the classroom. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: NSF Postdoctoral Fellowship in Biology FY 2021: Comparative methods and model clades for evolutionary developmental biology

Awardee: Church, Samuel H

Amount: \$138,000.00

Abstract: this action funds an nsf postdoctoral research fellowship in biology for fy 2021, integrative research investigating the rules of life governing interactions between genomes, environment and phenotypes. the fellowship supports research and training of the fellow that will contribute to the area of rules of life in innovative ways. the funded research will use large datasets to investigate how evolution leads to bio\*\*diversity\*\*. methods for collecting large amounts of data with thousands of measured biological traits are becoming increasingly common and inexpensive to generate. examples of such data include developmental assays of gene expression. as this data becomes more common, so do comparisons of these data across species. however, evolutionary biologists have warned for years that comparisons across species must be performed using mathematical models that account for how related species are, or they risk misidentifying patterns across species. this fellowship will focus on developing new methods for comparing data across species. this research is important given that, in this era of rapid global change, robust models of evolution are needed to accurately predict how bio\*\*diversity\*\* is likely to change in the future. furthermore, this research will broaden participation in science by recruiting and mentoring undergraduate students from underrepresented groups in computational biological analysis. this research project will result in a new comparative framework for analyzing high-dimensional data on gene expression across species. gene expression data are common in assays of developmental biology, yet current comparisons of these data across taxa often fail to consider the evolutionary non-independence of observations. there exists a rich literature of comparative methods designed to statistically compare traits across taxa, but their implementation for high-dimensional continuous traits faces technical limitations. to overcome these limitations, first the fellow will identify and extend evolutionary models to describe the distribution of expression data across taxa. this analysis will require the fellow to achieve specific training objectives, including seeking out advanced knowledge in mathematical modeling, to overcome common challenges in analyzing datasets that have many thousands of parameters. second, the fellow will apply these methods to real-world data on gene expression across tissues and species, testing hypotheses about the degree to which phylogeny, gene

pathway, and gene product type explain variation. the results of this study will be a comparative framework that can be immediately applied to datasets of gene expression across species, which will be released as free, publicly accessible, open-source software. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: NSF Postdoctoral Fellowship in Biology FY 2021: Evolution of the extended floral phenotype

Awardee: Freundlich, Grace

Amount: \$138,000.00

Abstract: this action funds an nsf postdoctoral research fellowship in biology for fy 2021, integrative research investigating the rules of life governing interactions between genomes, environment and phenotypes. the fellowship supports research and training of the fellow that will contribute to the area of rules of life in innovative ways. the fellow will investigate the effect of biotic interactions on the expression and evolution of floral traits. pollinators are a significant force of selection on floral traits, including size, color, and scent. floral tissues frequently harbor a **\*\*diversity\*\*** of microbes, however, which impact cues important for pollinator attraction, with consequences for host reproduction. despite the potential for such effects, it remains unclear whether microbes can modify pollinator-mediated selection on floral traits. after manipulating interactions among a flowering host, pollinator, and microbes the fellow will use chemical and molecular techniques to assess the strength and direction of selection exerted on floral traits by these biotic interactions. such research will advance pollination biology and inform understanding of factors promoting floral diversification. the fellow will also collaborate with local institutions and programs to broaden participation of underrepresented groups at the middle school, high school, and undergraduate levels through providing opportunities for learning and research. the fellow will test the hypothesis that floral microbes and pollinators jointly shape selection on floral phenotype. using fast-cycling brassica rapa

plants and an experimental evolution framework, the fellow will manipulate interactions among host plant, bumble bee (*bombus impatiens*), bacterium (*bacillus subtilis*), and/or yeast (*metschnikowia reukaufii*) to dissect biotic drivers of floral phenotypic evolution. more specifically, the fellow will address the following three objectives: 1) examination of interactive effects of microbes and pollinators on floral evolution, 2) characterization of molecular mechanisms underlying shifts in floral phenotype, and 3) assessment of reciprocal selection on microbial inhabitants of flowers. by considering such eco-evolutionary dynamics among interacting partners, and taking a multi-level selection approach that employs genomic, transcriptomic, and metabolomic approaches, this study will address an important but understudied component of pollination mutualism and the sources of variation upon which natural selection can act. in performing the research, the fellow will acquire new skills in genomics, transcriptomics, and metabolomics. finally, middle school, high school, and college students from groups underrepresented in the sciences will be included in the research, with the fellow also giving guest lectures in plant science courses and at outreach events. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: NSF Postdoctoral Fellowship in Biology FY 2021: Fluid homeostasis in the evolution of frog breeding phenology

Awardee: Juarez, Bryan H

Amount: \$138,000.00

Abstract: this action funds an nsf postdoctoral research fellowship in biology for fy 2021, broadening participation of groups underrepresented in biology. the fellowship supports a research and training plan for the fellow that will increase the participation of groups underrepresented in biology. the goal of this research is to understand the role of aquaporin proteins in allowing frogs to overcome harsh environments, and how this may be related to climate and breeding behaviors. aquaporins allow

water to move across cell membranes and therefore allow frogs to maintain water balance in many different environments. frogs might encounter harsh weather conditions during their reproductive period and must overcome them in order to reproduce and survive. the fellow will obtain data on the genetic **diversity** of aquaporins and other relevant traits from various species of frogs living in different habitats. laboratory experiments will be used to determine how different species may adapt to hot, cold, or dry conditions and eventually inform amphibian conservation efforts. if differences across species are observed, it is implied that aquaporins are important in allowing frogs to survive changing climates and are related to breeding behaviors in frogs. additionally, the fellow will design and implement free public workshops for graduate students providing practical guides for reporting statistical results and enhancing scientific reproducibility, with the goal of promoting the participation of historically underrepresented groups at the postdoctoral level. this research will test three hypotheses to determine the evolutionary relationship between behavior, climate, and genetic and functional **diversity** in aquaporin proteins: h1) breeding period duration across anurans is related to climate, h2) **diversity** in aquaporin sequences is influenced by climate, and h3) aquaporin gene expression is related to temperature/water availability. h1 and h2 will be analyzed using phylogenetic generalized least squares (pgls) regression while accounting for relevant traits such as body size or habitat preference. for h2, pairwise genetic distances will be obtained via generalized time-reversible models and then projected into a euclidean space (required for pgls regression) using multidimensional scaling. h3 will be analyzed using a phylogenetic multivariate analysis of variance model. it is expected that temperature will be one of the major factors influencing sequence **diversity**, gene expression, and breeding period duration. this research is important for understanding past biogeography and future conservation prospects in anurans. training objectives for the fellow include developing mentorship skills and learning to obtain and analyze data on climate, molecular sequences, and gene expression. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Social Preferences Among Transgender, Gender Nonconforming, and Gender Typical Children

Awardee: Jordan, Ashley Eliza

Amount: \$138,000.00

Abstract: this award was provided as part of nsf's social, behavioral and economic sciences postdoctoral research fellowships (sprf) program. the goal of the sprf program is to prepare promising, early career doctoral-level scientists for scientific careers in academia, industry or private sector, and government. sprf awards involve two years of training under the sponsorship of established scientists and encourage postdoctoral fellows to perform independent research. nsf seeks to promote the participation of scientists from all segments of the scientific community, including those from underrepresented groups, in its research programs and activities; the postdoctoral period is considered to be an important level of professional development in attaining this goal. each postdoctoral fellow must address important scientific questions that advance their respective disciplinary fields. under the sponsorship of dr. kristina olson at princeton university, this postdoctoral fellowship award supports an early career scientist investigating how gender diverse youth and teens reason about the social world. the transyouth project at princeton is a national, longitudinal study of the largest sample of prepubescent transgender and gender nonconforming youth and their siblings. this project addresses a longstanding issue in the field of gender development research. namely, that virtually all theorizing and empirical approaches to date assume that the sex a child is assigned at birth matches their lived gender identity. although this is true for many, in recent years transgender individuals?those who identify with the gender opposite their natal sex?have gained more visibility. thus, the time is ripe for developmental researchers to broaden the scope of their theorizing to include gender diverse youth. self-disclosure of one's identity is a precursor to many benefits, such as receiving social affirmation and building community

around one's identity. however, transgender youth must take into consideration the potential for discrimination and bullying that may follow. how transgender youth adjudicate between the option to disclose rather than conceal their identity is important, but not well understood. the goal of the project, entitled "social preferences among transgender, gender nonconforming, and gender typical children" is twofold. first the project assesses how transgender teenagers (13-18 years) evaluate those whom they have disclosed their gender identity to (aim 1). this aim employs a mixed-methods approach using thematic analysis to identify themes associated with teens' successful disclosure experiences, as measured by the teens' ratings of their chosen confidants' levels of support. second, the project empirically assesses how young children reason about disclosure decisions in a third-person context based on the characteristics of potential confidants, including the composition of their friend groups with respect to gender **\*\*diversity\*\*** (aim 2a). finally, this work will examine whether transgender teens' evaluations of their confidants is consistent with younger transgender children's reasoning about others' disclosure decisions (aim 2b). this project advances scientific knowledge that has the potential to support better outcomes for gender diverse individuals. further, this work will provide an empirical basis for how to better support gender diverse individuals by assessing how children across the gender identity spectrum reason about the benefits and burdens of gender identity disclosure. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: NSF Postdoctoral Fellowship in Biology FY 2021: Biophotonics, Species, and Relationships

Awardee: McCoy, Dakota E

Amount: \$138,000.00

Abstract: this action funds an nsf postdoctoral research fellowship in biology for fy 2021, integrative research investigating the rules of life governing interactions between genomes, environment and

phenotypes. the fellowship supports research and training of the fellow that will contribute to the area of rules of life in innovative ways. coral reefs, essential elements of the global ecosystem, depend on solar-powered symbioses: algae live inside marine reef animals, such as coral and giant clams, and photosynthesize to provide ready energy. however, increasingly environmental changes jeopardize the balance that maintains these animal-algal symbioses. to protect critically-threatened reefs worldwide, we face a powerful imperative to (i) explore how reef animals harness solar power so efficiently and (ii) understand threats to their intricate solar. in this project, the fellow will research optical adaptations and evolution in reef-dwelling symbiotic animals. the results will help us understand why corals bleach so severely while other symbiotic marine animals do not. along the way, the innate creativity of nature may inspire sustainable technologies for solar power. through three projects, the fellow will explore the following rule of life: how do animal hosts and their symbionts partner together to harness solar energy? in project 1, the fellow will research whether photosymbiotic acoels and anemones have adaptations to channel light toward their symbionts, and if so whether these adaptations resemble light-harnessing structures seen in other organisms (such as plants). as a result, this work will set the stage for comparative evolutionary analyses as well as, potentially, inspiring new solar panel research. in project 2, the fellow will test hypotheses about what selective forces drive **diversity** in biophotonic structures (from project 1) and colors across acoels and anemones. for example, are environmental influences? such as depth? less important than symbiotic pressures? such as species of symbiont? in project 3, the fellow will analyze why some animals are so susceptible to bleaching while others are resistant. specifically, i will assess whether certain biophotonic adaptations that concentrate light for photosynthesis could actually exacerbate bleaching ? potentially by causing organisms to heat up, or experience light shock, amidst warming waters. the fellow will learn and apply cutting-edge microscopy, applied physics, and materials science methods to marine biology (including hyperspectral imaging, transmission electron microscopy, and finite-difference time-domain simulations). this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's

intellectual merit and broader impacts review criteria.

Title: NSF Postdoctoral Fellowship in Biology FY 2021: General plasticity kinetics: developing a universal framework of developmental plasticity

Awardee: Jung, Julie

Amount: \$138,000.00

Abstract: this action funds an nsf postdoctoral research fellowship in biology for fy 2021, integrative research investigating the rules of life governing interactions between genomes, environment and phenotypes. the fellowship supports research and training of the fellow that will contribute to the area of rules of life in innovative ways. all multicellular organisms develop according to a body plan defined by their genes. however, developmental trajectories must also be flexible enough to respond to different environmental conditions. plastic traits can persist through a process known as genetic accommodation, which has been increasingly discussed as a major facilitator of novelty and divergence. this project aims to demonstrate developmental plasticity's value and prominence in evolutionary theory and to elucidate how phenotypes arise from the interplay between genotypes and the environment. to promote broad dissemination, the fellow will create an interactive web interface to visualize the parameters of any plastic trait and teaching modules for undergraduate courses in mathematics modeling and developmental biology. to promote retention and inclusion of historically excluded students in biology graduate programs, the fellow will develop workshop materials and establish a mentorship program for the **\*\*diversity\*\*** fellows program at the university of utah. the project will introduce a general framework for studying plasticity, drawing from principles of theoretical ecological and mathematical modeling (aim i) and then apply that universal model to a laboratory case study of mouth-form plasticity in the pristionchus genus of diplogastrid nematodes (aim ii). this research will span several scales in the hierarchy of life and use diverse methodologies to reveal three predicted outcomes: changes in plasticity, corresponding changes in

trait evolution, and the underlying molecular mechanisms of both. this work identifying the process of genetic accommodation in real time will tie developmental plasticity in response to environmental perturbations to rigorous theoretical and empirical laboratory approaches in an emerging model study system. this research has the potential to revise mainstream evolutionary biology to include a mature theory of how the environment and genes determine phenotypes during development. the fellow will experience training on mathematical modeling, functional genomics, and mentorship practices; these skills are required to tackle many of the most important modern problems in ecology and evolutionary biology. outreach activities include organizing a local peer-to-peer learning community to promote the practice of openscience and reproducibility in r. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: NSF Postdoctoral Fellowship in Biology FY 2021: Using a protoendothermic mammal to understand how body temperature influences nutrient absorption.

Awardee: Conner, Justin L

Amount: \$138,000.00

Abstract: this action funds an nsf postdoctoral research fellowship in biology for fy 2021, broadening participation of groups under-represented in biology. the fellowship supports a research and training plan for the fellow that will increase the participation of groups underrepresented in biology. the ability to generate a high internal body temperature independent of environmental temperature, has independently evolved twice in vertebrate animals, in mammals and in birds. however, there is a high cost (in terms of energy) to maintaining a high body temperature. this project focuses on understanding why there is increased body temperatures in modern mammals. to answer this question, the pi will use the tenrec as a model system. tenrecs are mammals from madagascar with a body temperature more variable than any other known mammal, and are an excellent model for

understanding the advantages of having a warmer body temperature. more specifically this project will focus on how body temperature influences digestion, which is connected to energy generation. to broaden participation, the fellow will set up two independent outreach events at the university of nevada las vegas aimed at increasing minority engagement within the department of life sciences. tenrecs have the remarkable ability to partially disconnect body temperature and metabolism. for instance, when maintained at 12°C, the body temperature of active tenrecs can range from ~13 to 32°C but resting metabolism of active tenrecs at 12°C may vary by 25-fold and is only partially dependent on body temperature. the fellow will exploit a unique mammalian system in order to understand how body temperature influences the nutrient extraction from food. this model will directly test the hypothesis that warmer body temperatures allow for greater nutrient extraction from foods. to test this nutrient extraction model for the evolution of endothermy (increased body temperature), an integrative approach will be used. utilizing whole animal, ex vivo, and in vitro 3d cell culture approaches to develop a multi-level approach the exploits whole animal, organ, and even cellular level investigation. fewer than 2% of all post-docs in stem fields are black/african american, which is an over 6-fold underrepresentation of the population as a whole. **\*\*diversity\*\*** within biological sciences will not increase unless underrepresented individuals are elevated thus, becoming an example of opportunities within this field. to broaden participation, the fellow will establish outreach events at the university of nevada las vegas, leveraging the Isamp program there. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: NSF Postdoctoral Fellowship in Biology FY 2021: Modeling the singular and additive effects of various anthropogenic disturbances using genomics

Awardee: Aviles-Rodriguez, Kevin J

Amount: \$138,000.00

Abstract: this action funds an nsf postdoctoral research fellowship in biology for fy 2020, broadening participation of groups under-represented in biology. the fellowship supports a research and training plan for the fellow that will increase the participation of groups underrepresented in biology. species are often affected by multiple human-created stressors simultaneously. however, disentangling the singular and additive effects of these human made stressors remains challenging. the fellow will use a technique called landscape genomics, which allows you to identify relationships between the environment and genetics of organisms, to build a model to understand the effect of human induced environmental change (urbanization, climate change) on a freshwater turtle, the puerto rican slider, in puerto rico. this species is impacted by both habitat loss to urbanization and the spread of an invasive species, the red eared slider. additionally, the fellow will facilitate community engagement at various levels. firstly, the fellow will work with puerto rican science educators to facilitate the use of inaturalist, which is an app used to discover, identify and report local bio\*\*diversity\*\*. secondly, the fellow will facilitate training in molecular laboratory techniques for underrepresented high school students near the sponsoring institution in new york. thirdly, the fellow will help connect students to graduate programs, fellowships, and professional opportunities through a facebook group called jicoteando created for this fellowship and also via various oral presentations. this research will require the application of population genomics, spatial analyses, and ecological studies. thus, the fellow will be provided training in many new skills and in interdisciplinary work. the landscape genomics models will test the singular and additive contributions of biotic and abiotic factors in relation to the species? functional genetic connectivity. to accomplish this, the fellow will first sequence genomic dna and then sample relevant landscape and ecological covariates across the study area. covariates will then be transformed into resistance surfaces characterizing their permeability or resistance to the movement of genetic variation. this transformation will be used to contrast singular and additive resistances arising from the measured covariates. the fellow will build important collaborations with conservation agencies with the goal of writing a management plan for the species informed by the impacts of landscape features and hybridization. the fellow will also gain

outreach experience working with students at various career stages. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: NSF Postdoctoral Fellowship in Biology FY 2021: Ecological and genetic structuring of a pathogen microbiome and its effect on virulence

Awardee: Kolp, Matthew Robert

Amount: \$138,000.00

Abstract: this action funds an nsf postdoctoral research fellowship in biology for fy 2021, integrative research investigating the rules of life governing interactions between genomes, environment and phenotypes. the fellowship supports research and training of the fellow that will contribute to the area of rules of life in innovative ways. infectious fungal pathogens are capable of hosting their own microbes, and these microbes can affect the relationship between the fungus and the plants and animals. the project goals are to develop general rules to better understand the relationship between these microbes and their pathogenic hosts, and how these relationships evolve. these goals are relevant to threats that pathogens pose to humans, agriculture, and bio\*\*diversity\*\*. the fellow will engage in a series of activities designed to highlight how basic discovery informs applied research for a broad audience. the fellow will hold a series of seminars for extension agents and agricultural stakeholders, highlighting the impacts of crop pest and pathogen life cycle on crop management strategies. further, the fellow will implement interactive lessons for elementary students in underserved schools in rural tn, using aphids, fungal pathogens, and other microbes. these lessons will expose students to beneficial impacts of microbes on human life. the fungal pathogen pandora neoaphidis is an important natural microbial enemy of aphids. the proposed work develops this pathogen as a tractable system for studying microbiome effects on host-pathogen interactions. the pathogen's microbiome of endosymbiotic bacteria is hypothesized to explain pea aphid epidemics.

the project will test whether endosymbiont **diversity** in *p. neoaphidis* from infected aphids collected from semi-natural areas recapitulates pathogen genetic **diversity** or ecological factors. the fellow will use metagenomics to determine the functional capacity of various endosymbiont taxa, with the goal of testing if *p. neoaphidis* endosymbionts correlate with difference in virulence among strains. this work will broaden understanding of how ecology and evolution shape pathogen associations with microbes. aphids are invasive agricultural pests, and fungal pathogens are used as a biological control of aphid populations. developing an understanding of how agricultural pests resist biocontrol agents is critical in integrated pest management. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Dimensions US-China: Collaborative Research: Consequences of diversity in Asian and American oak syngameons for functional variation, adaptation and symbiont biodiversity

Awardee: University of Oklahoma Norman Campus

Amount: \$136,646.00

Abstract: the world's approximately 425 oak species maintain species identity even while exchanging genes with their close relatives through hybridization. this history of evolution and genetic exchange has shaped the bio**diversity** of northern hemisphere ecosystems. oaks are ecologically diverse, with related species often growing in close proximity but specializing on areas of the forest landscape that differ in soil texture and moisture level or in the frequency of natural fires. gene exchange can move such ecological specializations between oak species, broadening their ranges and ability to respond to climate change. the impacts of these genetic exchanges may extend beyond the oaks themselves. oaks host an estimated 1000 gall wasp species worldwide and highly diverse communities of fungi associated with their roots (as mycorrhizae) and inside their leaves (as endophytes). using paired field surveys and common garden experiments the pis will

evaluate the effects of hybridization and introgression on the genetic, phylogenetic, and functional **diversity** of focal oak species and their symbionts in the us and china. this work will also provide inquiry-based k-12, undergraduate, and graduate education; critical natural history training to the public through a community-science initiative in oak phenology; and publications that will bring research to public audiences. two interdisciplinary teams of researchers, one based in the us and one in china, will investigate how genomic, functional, and phylogenetic **diversity** of oak trees shape the mycorrhizal fungi, endophytic fungi, and gall wasp and other insect communities that associate with them. research will focus on two related groups of interbreeding species: bur oak (*quercus macrocarpa*) and relatives in the us and bao li (*quercus serrata*) and relatives in china. the project has three objectives, each conducted in parallel in china and the u.s. in objective 1 the teams will perform range-wide phylogenomic surveys of natural populations to reconstruct genomic mosaics, characterize geographic patterns of leaf functional traits, and characterize functional and phylogenetic **diversity** of associated mycorrhizal fungi, leaf endophytic fungi, and gall wasps. in objective 2 common gardens will be planted across climatic gradients to evaluate the effects of genetic variation and population differentiation on oak functional and spectral traits and relative fitness in different climates, and how these influence the phylogenetic and functional **diversity** of oak-associated fungal and insect communities. in objective 3 the teams will use a second set of common garden experiments to evaluate how plant community and phylogenetic **diversity** affects focal oak species genetic, phylogenetic, and functional **diversity**. the project will provide an integrative perspective on how oak **diversity** within and among species impacts the broad **diversity** of oak-dominated ecosystems across the northern hemisphere. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Workshop on Leadership: Increasing Leaders from Historically Under-Represented Groups

Awardee: Pennsylvania State Univ University Park

Amount: \$135,177.00

Abstract: in this increasing complex world, stem leaders must have a broader education than science, technology, and engineering to be successful in addressing the leadership challenges required to solve the technological challenges facing the world. rising leaders need to have a grounding in the social and behavioral sciences and an appreciation for the cultural, economic, political, and educational differences of the people and communities who will use and/or be affected by the stem approaches they will be developing. additionally, addressing the underrepresentation of marginalized groups in leadership positions within the us stem enterprise is vital to ensuring that the nation has a robust and diverse stem workforce. this conference proposal will deliver a three-day workshop to document and learn from a multidecadal perspective the following: 1) characteristics of leaders from underrepresented groups in stem, 2) transformative efforts that increased representation of diverse stem leaders across various institutions (academia, public sector, non-profit sector, and private sector), 3) innovative **\*\*diversity\*\*** and inclusion perspectives from current leaders, 4) effective/emerging strategies regarding the development of next-generation leaders from underrepresented groups, and 5) approaches for the integration of stem with social sciences to facilitate processes for a **\*\*diversity\*\*** of early and mid-career scientists and engineers to gain leadership positions. while the number of leaders from underrepresented groups (urgs) has increased modestly over time, this increase has lagged the increase of individuals from urg in stem workplaces, which themselves do not yet reflect the demographics of the nation. this workshop has the potential of affecting various types of institutions that have lagged in utilizing fully the repository of national talent by involving policy makers at the highest level as well as strong leaders who can speak not only to the value of **\*\*diversity\*\*** but can also articulate the work and the processes behind their stories of success, thereby illuminating possible paths forward. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: CIF: An Ice Nucleation Cold-Stage for Research and Teaching

Awardee: North Carolina State University

Amount: \$132,755.00

Abstract: this community instruments and facilities (cif) award makes the north carolina state ice nucleation cold stage (nc state cs) freezing assay available as a community instrument facility. the instrument consists of a machine vision optical system to observe a thermally controlled surface. the main purpose of the instrument is to observe the freezing nucleation process of supercooled water droplets. the instrument is suitable for studying ambient ice nucleating particle concentrations and laboratory-based process-level studies of the nucleation process. the facility will be advertised at conferences, including conferences that exclusively target professional societies focused on fostering enhanced **\*\*diversity\*\*** in science. interactive educational content will be created and disseminated using a multi-user web-interface that can be used by instructors to supplement instruction in a wide range of undergraduate and graduate courses. this project contributes instrumentation and educational resources to tackle the problem of characterizing the abundance of ice nucleating particles in the atmosphere. by becoming a community instrument facility, the cold-stage technique will become more widely available to groups that do not specialize in instrument design. funds for the award will also yield a public design of a low-cost version of the instrument that can be self-manufactured. this award will enhance the ability of the broader scientific community to use the nc state ice nucleation cold stage freezing assay through the atmospheric and geospace sciences facility and instrument request process. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: STEPP-NET: Steppe Parasite Networks

Awardee: Georgia Southern University Research and Service Foundation, Inc

Amount: \$131,319.00

Abstract: this project focuses on collecting and describing mammals and their tapeworm and flea parasites from the grasslands of central asia. these parasites are highly diverse and ecologically important groups, and many are sensitive indicators of ecosystem quality; further, the parasitic infections they cause can have major negative impacts on wildlife. they also can play an important role in transmitting diseases from wild to domesticated species, and also to humans. however, knowledge of the **diversity** of parasite species, their geographic distributions, and the precise hosts they occur on and in remains highly fragmentary for much of the world. central asian mammals and their associated parasites are particularly highly imperiled but also little studied. this project will collect new material and study how tapeworm and flea parasites from the region evolve in conjunction with their mammalian hosts; it will also consider how the hosts and parasites have responded to various ecological changes across the region. this work is extremely time-sensitive, with many central asian ecosystems on the cusp of major land use change as economies shift and major construction occurs in the region. numerous specimens will be collected, and these will serve as a repository of parasite **diversity** useful for assessing how future global change influences the distribution of parasites and their hosts. this may ultimately improve public health outcomes. the work will also involve training the next generation of early-career stem researchers for careers in bio**diversity** science. the stepp-net project will rapidly advance discovery and description of species **diversity**, host associations, and community assembly, in two mammal-associated macroparasite clades - fleas and cestodes - across the vast grasslands of central asia. this region is a prototype for exploring host-parasite dynamics and spillover in response to human activity; historically, as a conduit for ancient silk road trade routes, and, currently, from intensifying land use changes and construction. stepp-net leverages existing museum specimens, new expeditionary collections in mongolia and kazakhstan, and genomic analyses of hosts and parasites to advance

knowledge of species boundaries, environmental and host niche breadth, and the exploration of novel host interfaces by focal parasite clades in response to global change pressures. a key outcome of stepp-net will be an extended specimen network for central asia, in which mammal and parasite specimens are durably linked to derived data and immediately useful in global bio\*\*diversity\*\* studies and public health initiatives. the project also creates opportunities for stem graduate and undergraduate students to participate across the spectrum of modern bio\*\*diversity\*\* science, from international fieldwork to specimen curation and digitization, genomics, and integrative taxonomy. it will build out this community of early-career stem researchers even further by developing undergraduate and graduate educational modules that are implemented across our institutions and hosted online for broader bio\*\*diversity\*\* literacy. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Redefining the footprint of deep ocean methane seepage for benthic ecosystems

Awardee: Occidental College

Amount: \$128,827.00

Abstract: this research examines the role of deep-sea organisms in determining the fate and footprint of methane, a potent greenhouse gas, on pacific continental margins. the investigators are evaluating the deep ocean methanosphere defined by the microbial communities that consume methane and the animals that directly feed on or form symbioses with methane-consuming microbes. they are also investigating animal communities that gain energy indirectly from methane, as well as those that take advantage of carbonate rocks, the physical manifestation of methane consumption in seafloor sediments. the study of methane seeps in the deep waters of both alaska (4400-5500 meters) and southern california (450-1040 meters) is enabling comparisons of the

methanosphere under different food-limitation and oxygen regimes. by applying diverse chemical, isotopic, microscopy, and genetic-based analyses to seep microbes and fauna, this study is advancing understanding of the contribution of methane to deep-sea bio\*\*diversity\*\* and ecosystem function, information that can inform management and conservation actions in us waters. in addition to training for graduate and undergraduate students at their home institutions, the investigators are collaborating with the alaska native science and engineering program (ansep). they are recruiting alaskan undergraduates to participate in the research, contributing to ansep?s online resources that promote interaction between scientists and middle and high school students, and participating in ansep?s annual residential career exploration in marine science programs to engage middle school students in learning about deep-sea ecosystems and the variety of career pathways available in marine related fields.

microbial production and consumption of methane is dynamic and widespread along continental margins, and some animals within deep-sea methane seeps rely on the oxidation and sequestration of methane for nutrition. at the same time, understanding of methane-dependent processes and symbioses in the deep-sea environment is still rudimentary. the goals of this study are to 1) examine the \*\*diversity\*\* of animals involved in methane-based symbioses and heterotrophic consumption of methane-oxidizing microbes and how these symbioses extend the periphery of seeps, contributing to non-seep, continental slope food webs; and 2) determine whether carbonates on the seep periphery sustain active methanotrophic microbial assemblages, providing a localized food source or chemical fuel for thiotrophic symbioses, via anaerobic oxidation of methane, or free-living, sulfide-oxidizing bacteria consumed by animals. the investigators are addressing these goals by surveying, sampling, and characterizing microbes, water, sediments, carbonates and animals at a deep seep site on the aleutian margin and a shallow site off southern california. shipboard experiments and laboratory analyses are using molecular, isotopic, geochemical, and radiotracer tools to understand transfer of methane-sourced carbon from aerobic methanotrophs under multiple oxygen levels, pressures, and photosynthetic food inputs. this approach offers a wide lens by which to examine the methane seep footprint, allow reinterpretation

of past observations, and identify new scientific areas for future study. improved characterization of the deep continental margin methanosphere informs climate science, bio\*\*diversity\*\* conservation, and resource management. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: A Data-Driven Employer-Academia Partnership for Continual Computing Curricular Change

Awardee: Rochester Institute of Tech

Amount: \$125,694.00

Abstract: this project aims to serve the national interest by improving the supply of well-prepared computer science professionals capable of addressing the needs of american employers in the public and private sectors. this project intends to build a national partnership between employers and academia to help identify and mitigate gaps between the competencies of computing graduates and the expectations of potential employers. the project will survey computer science educators and practitioners to develop a model that defines the competencies expected by potential employers. the project team then plans to test the model at three institutions of higher education in alabama ? the university of alabama, tuscaloosa, tuskegee university, and shelton state community college. finally, the project team intends to develop tools and methods for institutions to identify and implement competency-based educational approaches for computer science across the nation. the project plans to use three interconnected strands of evidence-based activities to institute transformational change in the involved communities. first, a national strand will engage u.s. faculty in developing competency-based curricula informed by industry practitioner feedback. second, a local pilot strand intends to create transformative curricular change based on student competencies using an evidence-based change model in the three alabama institutions. sociologists and

computing faculty on the team will help to understand, predict, and reduce barriers to competency-based employment of computing graduates from marginalized communities in the heart of the impoverished alabama black belt. the unique perspective relative to **\*\*diversity\*\***, equity, and inclusion needs should serve as a model for other computing departments. the third strand will develop competency-based surveys for practitioners and academics to identify and refine specific competencies that are hoped to drive continual curricular change. outcomes, including the change process, national workshops, and experiences from the local process will help with transferability in the computing education community. in addition to informing curricula, the project will provide valuable data for educational researchers to help close the gap between employers and higher education. finally, as the competency approach to curricular design is relatively new in computing and engineering disciplines, lessons from this project will have the potential to transform curricular review and design in other stem disciplines. the nsf iuse: ehr program supports research and development projects to improve the effectiveness of stem education for all students. through the institutional and community transformation track, the program supports efforts to transform and improve stem education across institutions of higher education and disciplinary communities. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: MRI: Acquisition of a Broad-Energy Germanium Detector at Western Washington University

Awardee: Western Washington University

Amount: \$124,892.00

Abstract: this award is made to western washington university (wwu) to purchase a broad-energy germanium gamma ray detector to expand research and education programs in environmental science and geology. the earth possesses many naturally occurring radioactive elements that emit gamma radiation. by measuring the quantity and distribution of these elements, researchers can

estimate the rates of important processes, such as the burial of sediment and organic carbon, removal of contaminants from seawater, and the mixing and transport of important particulate materials including carbon, metals, and organic contaminants. the instrument will allow students and faculty at wwu to quantify sedimentary processes, characterize past environments, and to assess changes in land use, pollution, and other natural conditions over time. the research community's interest in the use of our existing gamma detector and our associated expertise has now exceeded our ability to accommodate the demand. the expanded capabilities of this instrument will enable wwu students and faculty to address new environmental problems, take on additional research projects, improve the design of existing projects, and expand our network of collaborators at the global scale. the new broad-energy germanium detector (mirion be3825) will support the research and teaching programs of eight senior personnel and their associated students at wwu. these users all have research questions that can be addressed using gamma-emitting radionuclides, with applications ranging from bioturbation and sediment accumulation to tribal coastal clam gardens and estuarine carbon burial, to lake paleo-genetics and riparian geomorphological development. while our existing detector is in continuous use measuring low-energy gamma emitters such as pb-210 and th-234, the new broad-energy germanium detector will also enable the measurement of higher-energy gamma emitters such as cs-137, be-7, zn-65, and fe-59, allowing for a much greater number of users, more educational opportunities, and a greater **\*\*diversity\*\*** of instrument applications. as a non-phd granting institution, wwu places a strong emphasis on undergraduate and masters-level research and education. the new instrument at wwu will be made available not only for faculty-driven research but also for student-led thesis research and class projects to train the next generation of scientists. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: MRI: Acquisition of an Inductively Coupled Plasma-Mass Spectrometer for Quantitative Elemental Analysis of Natural and Engineered Materials

Awardee: University of Oregon Eugene

Amount: \$122,856.00

Abstract: this award is supported by the major research instrumentation and the chemistry research instrumentation programs. the university of oregon at eugene is acquiring an ion chromatograph, inductively coupled plasma-mass spectrometer (ic-icp-ms) to support professor shannon boettcher and colleagues krista mcguire and matthew polizzotto. in general, mass spectrometry (ms) is one of the key analytical methods used to identify and characterize small quantities of chemical species in complex matrices. in a typical experiment, the components flow into a mass spectrometer where they are ionized, and the ion masses are measured. this highly sensitive technique allows detection and determination of the structure of molecules in a complex mixture. the ionization using the inductively coupled plasma allows detection of metal ions and several non-metals present in very small concentrations. the ion chromatograph component allows separation of metal ions from mixtures, thus improving the characterization of the various components. the acquisition strengthens the research infrastructure at the university and regional area since this technology is accessible to students, faculty and researchers throughout several departments such as chemistry, biochemistry, materials science institute, earth sciences, biological sciences and anthropological sciences. the team is designing a research program to train new phd students to be mentors to k-12 students, by

showing them how to quantify metal ion content in soil and water sources and a plan to support academic and industrial partnerships through the facility denominated center for advanced material characterization at oregon (camcor) where the instrument is located. the award of the ic-icp-mass spectrometer is aimed at enhancing research and education at all levels. it is especially useful to determine species that function as electrocatalysts and for the study of aquifer mineral complexity and redox reactivity. the instrumentation is also used to investigate processes underlying biotransformation of arsenic and other contaminants in aquifers as well as plant-soil-microbial associations contributing to maintenance of tree **\*\*diversity\*\*** and nutrient cycling in tropical forests. the instrument also serves researchers assessing interactions of metal ions with nucleic-acid biomolecules and the preparation of precision-engineered nanoparticles. the mass spectrometer aids characterization of trace elements in volcanic and hydrothermal minerals. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Workshop: ProVis-EER: Developing Professional Vision into Empirical Practices within Engineering Education Research (EER) though Digital Apprenticeship

Awardee: George Mason University

Amount: \$119,505.00

Abstract: the preparation of a future engineering workforce depends critically on our ability to provide excellence in training and through our efforts to train a diverse range of stakeholders for the engineering profession. increasingly within the united states institutions are creating programs, courses, and centers to support the preparation of the future engineer. this institutional and education infrastructure depends on a better and deeper understanding of how engineering education works best in order to support their efforts and initiatives. this project will contribute to this mission by increasing and improving the capacity of engineering educators to undertake research on engineering education. through this series of workshops newcomers to the field will be able to learn first-hand from scholar-experts in the field. the online nature of the workshops will ensure that a large number of participants are able to undergo the sessions. furthermore, the resources created as part of this project will be available for future training purposes. overall, this work is crucial for the growing field of engineering education and the ability of future engineering educators to learn from a diverse set of scholar-experts will broaden the kinds of research that are done as well as the outcomes of the research. this project aligns with nsf's investment in the research in formation of engineers (rfe) program by creating better engineering education researchers that can support the training of future engineers and who can undertake better research for us to know how to create a more inclusive engineering workforce for the future. building capacity for engineering education research (eer) is a core goal of nsf and organizations such as the american society for engineering education (asee) and the national academies of sciences, engineering, and medicine (nasem). over the past decade the community has made significant gains towards achieving this objective as evidenced by increasing number of departments and centers directed towards engineering education across institutions. propagation of eer practices has largely been through face-to-face interactions, including doctoral programs, working in research laboratories, and workshops and tutorials at professional development meetings. these in person engagements and events are prohibitive for many who would benefit from developing a better understanding of how research is

conducted. they also limit new researchers in exposure to a broader **\*\*diversity\*\*** of views and research practices. this proposed series of digital workshops are designed as a ?swift apprenticeship? experiences to increase the formation of eer practitioners by creating exemplars of engineering education research practices that take the learner through the entire lifecycle of a project and provide an avenue for learning by example, scaffolded by experts. experts will focus on one of their exemplary published research papers and deconstruct/reconstruct how that research was done and the paper produced including matters of theory, methods, and review. the reconstruction will take place as a conversation with the pi/s which will be captured on video and audio and drafts of papers and other relevant artifacts will be collected and shared. it will also invite questions from a set of novice participants and commentary from other experts to provide another viewpoint and additional context on research practices. this project will benefit engineering education graduate students, engineering graduate students and faculty in other disciplines interested in engineering education research, and postdoctoral scholars. this work will contribute to research on engineering education, especially the use of professional vision and scaffolding for novices, and on transfer learning for research practices. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Examining the Vulnerability and Recovery of Small Farms to Natural Hazards and the Impact to Rural Community Resilience

Awardee: Texas A&M University

Amount: \$118,102.00

Abstract: this disaster resilience research grant (drrg) project contributes to the advancement of national health, prosperity and welfare by creating new knowledge on disaster recovery for the agricultural industry. despite the criticality of agriculture to u.s. and global food production, the lack

of economic **diversity** and prevalence of agriculture in many rural areas, particularly in the central us, is theorized to be a major contributor to low disaster resilience. resilience is a complex function of socio-economic dimensions and the built environment; and the population, economics, and physical infrastructure that comprise agricultural regions are distinct from the urban and suburban areas that are the common focus of most disaster and community resilience studies. this research generates a fundamental understanding of the resilience of farms and agriculture-prevalent rural communities in the face of severe windstorms, which will be of broad benefit to society and to national resilience. the research team will identify, evaluate, and recommend actions to enhance resilience of farms. to maximize the impact of these findings, the team will partner with the extension disaster education network for outreach and technology transfer. implementation of these mitigation measures can transform the disaster resilience of rural and agricultural regions, safeguarding the lives of citizens, regional and national economies, and global food production. the long-term goal of this research is to enhance the resilience of rural communities to natural hazards, which requires state-of-the-art research on the infrastructure that support farm operations, the recovery processes of individual farms, and the interaction of individual farms within the regional agricultural economy. as a first step towards enhancing rural resilience, the interdisciplinary team will conduct a three-year research project carefully tracking resilience from hazards to structures to farms to communities. the project is characterized by two primary goals. the first goal is to generate a fundamental understanding of the vulnerability and recovery of farms following windstorms through longitudinal reconnaissance of impacted agricultural communities, surveys of impacted farmers, correlation of hazard intensity with infrastructure response, and the examination of the linkages between recovery of individual infrastructure with farm-level recovery. the second goal is to develop and validate a risk-informed resilience assessment framework comprised of a farm-level resilience factors and community-level economic analyses to support decisions on business continuity and infrastructure investment for farms and the broader agriculture-prevalent rural communities. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the

foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Digitization TCN: Extending Anthophila research through image and trait digitization (Big-Bee)

Awardee: University of New Hampshire

Amount: \$117,425.00

Abstract: declining populations of bees impact plant-pollinator interactions in both natural and agricultural systems. while bees and other insects pollinate most wild plants, and are critical to sustain a large proportion of global food production, they are decreasing in both numbers and **\*\*diversity\*\***. our understanding of the factors driving these declines is limited because we lack sufficient data on the distribution of bee species, and on the behavioral and anatomical traits that may make them either vulnerable or resilient to human-induced environmental changes, such as habitat loss and climate change. fortunately, wild bees have been collected by researchers and deposited in natural history collections for over 100 years, retaining a wealth of associated attributes that can be extracted from specimen images. this project will digitally capture data and images from these historic specimens, develop tools to measure bee traits from these images, and generate a comprehensive bee trait and image dataset to measure changes through time. this will increase our understanding of specific traits that put bee species at risk of decline - a critical need for both sustaining our agricultural economy and the conservation of our natural resources. in addition, the large image datasets created by this project can be used for new artificial intelligence identification tools that will help improve our future pollinator observation and monitoring efforts. the big-bee thematic collection network (big-bee tcn) will create over one million high-resolution 2d and 3d images of bee specimens, representing over 5,000 worldwide bee species, including all of the major pollinating species of the united states. the big-bee network includes 13 institutions and partnerships with us government agencies. novel mechanisms for sharing image datasets will be developed and

datasets of bee traits will be available through an open data portal, the bee library, for research and education. the big-bee project will engage the general public in research through community science via crowdsourcing trait measurements and data transcription from images. in addition, training and professional development for natural history collection staff, researchers, and university students in data science will be provided through the creation and implementation of workshops focusing on bee traits and species identification. all data resulting from this award will be shared with and publicly available through the national digitized biocollections resource, [idigbio.org](http://idigbio.org). this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Reproductive heterogeneity in the structured coalescent framework

Awardee: Kennesaw State University Research and Service Foundation

Amount: \$112,256.00

Abstract: curbing the effects of pathogens and securing the survival of endangered or commercially exploited species is a matter of national interest. while collecting genetic data on these pathogens

and endangered species has become standard over the last decade, the data requires translation and analysis to be useful for policy decisions. these data are commonly used in models that describe both the recent and ancient history of the species. these models are founded on theoretical population genetics and are often not very flexible. this research addresses the assumption that the populations that are being studied have a relatively constant number of offspring per generation. scientific observation has shown that this assumption is incorrect. for example, some sars-cov-2 strains are more successful in infecting people than others, suggesting that the ancestor with a new mutation has many more 'offspring' than others. this research generalizes the common assumption and constructs a framework that allows for the improvement of these population models by offering an increase in accuracy and a decrease in bias. this research will result in the creation of a software tool that will benefit the research community and train the next generation researchers. accurate estimates of population size and genetic **diversity** will lead to better control of pathogen outbreaks, regulation of catch quota for commercial fishing, and maintenance of endangered species. this research explores the effect of heterogeneity of offspring production on the genealogy of a population using (1) a theoretical framework that can handle heterogeneity and the development of software to infer this heterogeneity from genomic data. this framework is based on the fractional coalescent expanded to multiple, structured populations. the research extends a single-population derivation of the fractional coalescent that incorporates offspring variability as a random variable. these new methods will be incorporated into the widely-used open-source computer software migrate. the new approach will then be compared with multi-merger coalescent methods using artificial data. these data are generated using (2) a simulator taking into account environmental quality changes within and among populations affecting the number of offspring an individual can have. (3) analyses of the effect of heterogeneity for many biological datasets over a broad range of species with different life histories: from viruses to humpback whales and from small geographic scale to large scales. these biological datasets will be analyzed in collaboration with practical scientists. software and tutorials will be reported on <http://popgen.sc.fsu.edu> and

<https://peterbeerli.com>. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: LightningBug, An Integrated Pipeline to Overcome The Biodiversity Digitization Gap

Awardee: Harvard University

Amount: \$111,116.00

Abstract: insects are the largest and most diverse class of animals on our planet where they play essential roles in ecosystems and the services those provide to society. entomologists have long been engaged in collecting, preserving and depositing nearly one billion insect specimens at natural history museums around the globe. these collections form the basis for much of our knowledge about insects and provide critical information about the past from which scientists can assess current and future global change impacts. to fully realize the value of these collections, data from insect specimens must first be digitized. however, their small size, delicate structures, and traditional

storage and labeling methods creates enormous challenges for large-scale digitization. consequently, at present, only 5% of specimens have transcribed labels and less than 1% of specimens are imaged. the lightningbug project will break through this digitization bottleneck by establishing a semi-automated workflow involving advancements in robotic multi-view imaging, information extraction and 3d reconstruction. results from this work will provide researchers with the unprecedented capability to capture specimen metadata representing time, place and taxonomic identity along with accurate three-dimensional surface morphology representing color and shape. these investigators expect lightningbug and related technologies will promote ecomorphological studies at a scale that has not been possible to date. the lightningbug project seeks to create an end-to-end pipeline for high-throughput data acquisition from pinned insects in entomological collections. to accomplish this goal, it will: (1) further develop an existing hardware and software platform to capture multi-view imagery of both labels and specimens; (2) build robust algorithms to automatically process fragmentary views of multiple labels into separate integrated "virtual labels;" (3) connect virtual labels to structured text extraction services; and (4) apply photogrammetric analysis to assemble the 3d shape and structure of specimens. guided by real-world science use cases that highlight the use of specimen-based multi-view imaging in studies of global change and functional morphology, the entomological collections of the yale peabody museum and the harvard museum of comparative zoology will be used in rigorous test-case implementations. results will include robust sets of annotated multi-view images, 3d models of specimens (point clouds, textured meshes), 2d reconstructed "virtual labels" and digitized specimen metadata generated from those labels. these digital specimens will present new challenges for data preservation and access, but they will also catalyze new solutions for large-scale storage and delivery of research imagery. this challenge will be addressed via a partnership with morphosource to develop a linked institutional repository model for data access to large digital assets such as those produced by multi-view imaging. ultimately, the ability to capture multi-view image suites and generate virtual specimens at scale will permit new avenues for remote access to research resources, and enable the application

of computer vision and machine learning to trait identification and evolution, species recognition and new species discovery. label data from pinned insects will give researchers access to critical temporal and geospatial information necessary for relating changes in bio\*\*diversity\*\* to other biotic and environmental variables. it will also provide collections staff with a complete digital portrait of their holdings, which can enable historical research, streamline collections use and tracking, and improve data quality control. results from this project will also have applications beyond the natural history collections and research communities, such as computer graphics, product imaging, motion pictures, 3d animation, virtual and augmented realities, and education. more information and results from this project can be found at <http://lightningbug.tech> this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Digitization TCN: Collaborative Research: Bringing Asia to digital life: mobilizing underrepresented Asian herbarium collections in the US to propel biodiversity discovery

Awardee: Bernice P Bishop Museum

Amount: \$109,530.00

Abstract: asia is the largest continent on earth, and includes the world's tallest mountains, lowest landscapes, and habitats ranging from arctic tundra to tropical rainforests and mangroves to deserts. the plants of this region are incredibly diverse in their identities and functions. more than one-third of the world's 350,000 plant species grow in asia and include tiny alpine cushion plants, medicinal herbs, ancient crops, and some of the planet's tallest rainforest trees. but documentation of this \*\*diversity\*\* remains inaccessible and research about it is difficult because most herbarium specimens of asian plants have not been digitized. the all asia thematic collections network (tcn) will mobilize online 15 million specimens of asian plants currently housed in the us and around the world. the project will especially focus on digitizing specimens from the unique and critically

endangered bio\*\*diversity\*\* hotspots of southeast asia and the himalaya-hengduan region. these mobilized digital data will accelerate research to conserve endangered plant species and understand the interacting effects of evolution and global environmental change on plant species \*\*diversity\*\*. the project will apply state-of-the-art informatics tools and high-throughput digitization methods to efficiently and affordably digitize an unprecedented number of herbarium collections. this effort will connect and build long-lasting relationships among 25 large and small consortium institutions in the u.s., europe, and asia. the focal areas from which specimens will be digitized encompass five bio\*\*diversity\*\* hotspots that include ~20% of the world's vascular plant flora and historically spanned 3 million km<sup>2</sup> of primary vegetation that now covers less than 300,000 km<sup>2</sup>. fundamental bio\*\*diversity\*\* data for these bio\*\*diversity\*\* hotspots are lacking, along with the necessary baselines required to characterize species' identity, range, and responses to ongoing climatic change. the overall goals of the all asia tcn are to rapidly digitize herbarium specimens of asian plants to advance bio\*\*diversity\*\* discovery and provide critical baseline assessments essential for establishing floristic change in the anthropocene. the project will accomplish this by (1) digitizing 3 million asian vascular plant specimens from u.s. herbaria; (2) developing and applying novel informatics tools and high-throughput digitization methods to massively scale herbarium digitization; (3) aggregating and mobilizing the digitized records from the project with those by international partners in china, france, the netherlands, and russia to establish a single online all asia portal of ca. 15 million specimens; and (4) enhancing opportunities for early career learners in science, technology, engineering, and mathematics by stimulating synergies between bio\*\*diversity\*\* and computer scientists who will use design thinking principles to create real-world informatics solutions to bio\*\*diversity\*\* challenges. to stimulate curiosity in plant \*\*diversity\*\* and botanical exploration among the general public, the consortium members will host several asia-themed notes from nature virtual expeditions to facilitate additional specimen digitization by citizen-scientists. digitized specimen data mobilized through this project will be shared and made available through idigbio.org. this award reflects nsf's statutory mission and has been deemed

worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: LEAPS-MPS: The representation theory of combinatorial categories

Awardee: Bowdoin College

Amount: \$105,432.00

Abstract: this award is funded in whole or in part under the american rescue plan act of 2021 (public law 117-2). in mathematics, a finite graph refers to a finite collection of points with line segments, called edges, connecting them. for example, a triangle is a graph with three points and three edges, while the letter "h" could be viewed as a graph with 6 points and 5 edges. despite the simplicity of this description, graphs have proven themselves to be one of the most important tools in the modern mathematical toolkit, being critical in applications to, for instance, large networks and robotics. the projects of the current award seek to further the state of the art in the study of graphs in key ways related with the two aforementioned applications. in particular, one project seeks to understand the sizes of large independent (without a single edge connecting them) collections of points within the graph, whereas another relates to ways in which large networks expand over time. the final project considers scenarios of a collection of robots randomly moving on the graph as if it were a track, while not being allowed to collide, and showing the extremely interesting behavior that can result from this. in addition to these research concerns, this grant will be used in furthering educational standards for students of various backgrounds and skill levels. this includes attaching a "growing up in science" series to existing student seminars, supplying funding for the local awm chapter, using funds to send students to national conferences which specialize in **\*\*diversity\*\*** in research, and funding for summer research opportunities. this project builds on previous work, which developed a framework for studying families of highly symmetric graphs using combinatorial categories. this work lends itself to a variety of natural conjectures, including one that would imply certain regular

behaviors in the independence numbers of graphs in these families. these conjectures comprise the first proposed project. the second project applies a similar categorical framework to families of discrete groups, including automorphism groups of free groups and integral special linear groups. it has been observed that various group theoretic properties, such as kazhdan's property (t), seem to behave stably in these families. it is our belief that this framework can illuminate and expand upon our understanding of groups with property (t) and thereby our understanding of expander graphs. finally, recent work has presented a model for random braiding in the configuration space of a tree. this model has an associated covariance matrix, which has been conjectured to uniquely identify the tree; a feature which the topology of the configuration space lacks. furthermore, the pi has also devised a random model for graph configuration spaces that may be used to detect the presence of exotic torsions in homology. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: STEPP-NET: Steppe Parasite Networks

Awardee: Northern Michigan University

Amount: \$105,402.00

Abstract: this project focuses on collecting and describing mammals and their tapeworm and flea parasites from the grasslands of central asia. these parasites are highly diverse and ecologically important groups, and many are sensitive indicators of ecosystem quality; further, the parasitic infections they cause can have major negative impacts on wildlife. they also can play an important role in transmitting diseases from wild to domesticated species, and also to humans. however, knowledge of the **diversity** of parasite species, their geographic distributions, and the precise hosts they occur on and in remains highly fragmentary for much of the world. central asian mammals and their associated parasites are particularly highly imperiled but also little studied. this project will collect new material and study how tapeworm and flea parasites from the region evolve in conjunction with their mammalian hosts; it will also consider how the hosts and parasites have responded to various ecological changes across the region. this work is extremely time-sensitive, with many central asian ecosystems on the cusp of major land use change as economies shift and major construction occurs in the region. numerous specimens will be collected, and these will serve as a repository of parasite **diversity** useful for assessing how future global change influences the distribution of parasites and their hosts. this may ultimately improve public health outcomes. the work will also involve training the next generation of early-career stem researchers for careers in bio**diversity** science. the stepp-net project will rapidly advance discovery and description of species **diversity**, host associations, and community assembly, in two mammal-associated macroparasite clades - fleas and cestodes - across the vast grasslands of central asia. this region is a prototype for exploring host-parasite dynamics and spillover in response to human activity; historically, as a conduit for ancient silk road trade routes, and, currently, from intensifying land use changes and construction. stepp-net leverages existing museum specimens, new expeditionary collections in mongolia and kazakhstan, and genomic analyses of hosts and parasites to advance

knowledge of species boundaries, environmental and host niche breadth, and the exploration of novel host interfaces by focal parasite clades in response to global change pressures. a key outcome of stepp-net will be an extended specimen network for central asia, in which mammal and parasite specimens are durably linked to derived data and immediately useful in global bio\*\*diversity\*\* studies and public health initiatives. the project also creates opportunities for stem graduate and undergraduate students to participate across the spectrum of modern bio\*\*diversity\*\* science, from international fieldwork to specimen curation and digitization, genomics, and integrative taxonomy. it will build out this community of early-career stem researchers even further by developing undergraduate and graduate educational modules that are implemented across our institutions and hosted online for broader bio\*\*diversity\*\* literacy. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Contribution of mafic magmatism to upper crustal batholiths: A case study of the Sierra Nevada batholith

Awardee: Pomona College

Amount: \$104,344.00

Abstract: the dense crust beneath earth's oceans is regularly driven beneath the continents in a tectonic process called subduction, which results in the formation of magmas. such magmas ascend and create long chains of volcanoes like the cascades of the northwest united states or the andes in south america. over time, magmatism at subduction zones has helped build earth's continents. these magmatic processes concentrate silica to create thick and buoyant continents that stand higher than surrounding oceans and oceanic crust, which is a unique feature of our planet. this continental crust is an important source for resources essential to human existence, but the processes that concentrate silica in magmas are not fully understood. this research will study

magmatic processes in the sierra nevada mountain range of california, which is the ancient ?plumbing system? from the insides of subduction zone volcanoes from hundreds of millions of years ago, now exposed at earth?s surface. this work will study the chemistry of mafic (more magnesium and iron-rich, lower silica) rocks that represent an important compositional ingredient to create the high-silica rocks that form the bulk of the continents. extensive existing work on the high-silica rocks at this location will provide context for new measurements of the mafic end-member composition to understand the magmatic processes that build continents. the research will support collaboration between caltech and pomona college, including the mentoring of a female graduate student (caltech) and multiple undergraduate/post-baccalaureate students (pomona), as well as early career support for a female faculty member (caltech). in addition, earth science classroom lessons and field trips for middle and high school students from the big pine unified school district (bpusd) in owens valley, located within study area will be developed and conducted. bpusd serves a student population that is ~50% native american and >40% latinx, two under-represented groups in geosciences. the ultimate goal is to increase participation and interest of under-represented students in geosciences through place-based and culturally appropriate lessons that successfully aligned indigenous ways of knowing and scientific practices with western science models the formation of high-silica arc batholiths is an enduring petrologic problem. during flux-melting of the mantle wedge at subduction zones primitive basalts are produced. upon ascent into the crust, further differentiation of these basalts is required to form more silicic derivative melts. although field and experimental studies highlight the importance of lower crustal (>0.7 gpa) fractional crystallization of primitive basalts in generating high-silica melts, this process in detail cannot produce the composition of arc batholiths. in particular, deep crustal fractional crystallization generates peraluminous intermediate and silicic melts, compositions that are not widely observed in arc batholiths. to reconcile these observations, this research will test the following hypothesis: deep crustal differentiation produces high-al, low-mg basalts, as well as, evolved mildly peraluminous granitic melts. these melts represent endmembers that can mix to form the compositional

**\*\*diversity\*\*** of granitoids observed in arc batholith. testing this mixing-model hypothesis has been limited due to the relative lack of studies focusing on the mafic endmember. although volumetrically minor and relatively less-studied compared to high-silica granodiorites to granites that dominate batholiths, mafic plutons (non-primitive gabbros and diorites) are widely present in the upper crust of accreted arc sections. through a collaboration between caltech and pomona college this research will investigate the bulk-rock and mineral major/trace element chemistry, geochronology, and oxygen & strontium isotopic compositions mafic plutonic bodies across a transect from a classic continental arc locality, the sierra nevada batholith. this data will be placed in the context of both existing and new granitoid data, as well as, quantitative geochemical and rheologic models to understand whether these mafic plutonic bodies represent suitable mixing endmembers in the production of batholithic granitoids. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Explaining Differential Success in Biodiversity Knowledge Commons

Awardee: Purdue University

Amount: \$103,752.00

Abstract: scientists increasingly rely on community-governed digital portals to store and access open data. while these digital portals have improved access to data and other scientific products, portals are expensive to implement, challenging to maintain, and often fail to have uptake among key stakeholders. like those working in other areas of the digital economy, scientists have increasingly adopted platforms to implement and tailor portals to particular communities and needs, a model that lowers infrastructure costs and enables benefits of scale across networked portals. yet portals built from the same platform nonetheless show a large variation in their outcomes. participation in any particular portal is often short-lived and the impacts of data portals on the scientific process are

challenging to evaluate; portal usage typically fails to map onto traditional measures of research productivity such as publications and citation counts. this project is the first to systematically investigate scientific data portals built from a common platform in order to understand portal communities and outcomes. the research design, which compares bio\*\*diversity\*\* data portals, will inform studies of other platforms and digital knowledge commons, such as open source software and peer-production communities. specific findings and recommendations will be shared with bio\*\*diversity\*\* portal stakeholders regarding the effective design and use of these portals in order to improve uptake and access to these important species data and facilitate science and decision making around environmental change. this project uses fuzzy set qualitative comparative analysis (fsqca) to analyze open data portals as a kind of knowledge commons that impose minimal restrictions on access or reuse. the study sample comprises the 37 active and 4 inactive bio\*\*diversity\*\* data portals built from the symbiota platform, one of the largest and earliest scientific data platforms still under continual development, with hundreds of participating bio\*\*diversity\*\* collections and several dozen individually managed portals. in 2020, symbiota portals collectively provided access to over 60 million bio\*\*diversity\*\* data records and accounted for 90% of web traffic accessing specimens digitized through the nsf's advanced digitization of bio\*\*diversity\*\* collections (adbc) program, which has invested over \$50 million in this area to date. the project synthesizes across multiple types and sources of quantitative and qualitative data to identify why some of these portals achieve sustained growth and others do not. to do so, the project collects and analyzes up to ten years of analytics and other information from the portals, including tracked usage data, community building activities, features of portal governance, and resource inputs, as well as observation data collected during portal site visits and interviews with a stratified sample of portal managers. the fsqca approach enables comparative inferences about those portal features most likely to foster productive and sustained outcomes, including collective benefit and building inclusive scientific communities. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review

criteria.

Title: Collaborative Research: A Data-Driven Employer-Academia Partnership for Continual Computing Curricular Change

Awardee: University of New Hampshire

Amount: \$101,794.00

Abstract: this project aims to serve the national interest by improving the supply of well-prepared computer science professionals capable of addressing the needs of american employers in the public and private sectors. this project intends to build a national partnership between employers and academia to help identify and mitigate gaps between the competencies of computing graduates and the expectations of potential employers. the project will survey computer science educators and practitioners to develop a model that defines the competencies expected by potential employers. the project team then plans to test the model at three institutions of higher education in alabama ? the university of alabama, tuscaloosa, tuskegee university, and shelton state community college. finally, the project team intends to develop tools and methods for institutions to identify and implement competency-based educational approaches for computer science across the nation. the project plans to use three interconnected strands of evidence-based activities to institute transformational change in the involved communities. first, a national strand will engage u.s. faculty in developing competency-based curricula informed by industry practitioner feedback. second, a local pilot strand intends to create transformative curricular change based on student competencies using an evidence-based change model in the three alabama institutions. sociologists and computing faculty on the team will help to understand, predict, and reduce barriers to competency-based employment of computing graduates from marginalized communities in the heart of the impoverished alabama black belt. the unique perspective relative to **\*\*diversity\*\***, equity, and inclusion needs should serve as a model for other computing departments. the third strand will

develop competency-based surveys for practitioners and academics to identify and refine specific competencies that are hoped to drive continual curricular change. outcomes, including the change process, national workshops, and experiences from the local process will help with transferability in the computing education community. in addition to informing curricula, the project will provide valuable data for educational researchers to help close the gap between employers and higher education. finally, as the competency approach to curricular design is relatively new in computing and engineering disciplines, lessons from this project will have the potential to transform curricular review and design in other stem disciplines. the nsf iuse: ehr program supports research and development projects to improve the effectiveness of stem education for all students. through the institutional and community transformation track, the program supports efforts to transform and improve stem education across institutions of higher education and disciplinary communities. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: SPARC: Facilitating Research, Experimentation, and Education in Spatial Archaeometry

Awardee: Dartmouth College

Amount: \$101,572.00

Abstract: the spatial archaeometry research collaborations (sparc) program promotes the use of spatial analysis, 3d modeling, as well as satellite, aerial, and terrestrial remote sensing in archaeological research projects. the things archaeologists study?from artifacts to sites to landscapes?almost always have a spatial component and spatial analysis is therefore central to contemporary archaeological investigations. today, the increasing availability and sophistication of geospatial technologies is not merely generating new data but is facilitating entirely novel means of engaging with the archaeological record and exploring the human past. however, the high costs of

instrumentation and software, combined with the expertise they require, create hurdles for many archaeologists who aim to deploy geospatial technologies in research projects. sparc 1) facilitates high-impact spatial archaeometric research, 2) advances emerging methodologies towards greater community use, 3) promotes this new knowledge across the discipline, and 4) promotes inclusion of junior and underrepresented scholars and institutions in leadership roles and in its training schema. through its innovative approach to supporting collaborative archaeological research, the sparc program makes costly geospatial technologies and specialized domain expertise available to researchers from a wide range of backgrounds, including early career scholars and those at minority serving institutions, enhancing **\*\*diversity\*\***, equity, and inclusion within archaeological research. the program also provides education and training opportunities for students and professionals seeking to use geospatial techniques in their own research, broadening the impact of the program far beyond individual supported projects. the sparc program supports archaeological researchers seeking to integrate geospatial technologies and methods into their investigations by facilitating collaborations with research faculty and staff and the technological infrastructure from the university of arkansas' center for advanced spatial technologies (cast), dartmouth college's spatial archaeometry lab (sparcl), and the university of arkansas' microct imaging consortium for research and outreach (micro). researchers apply to the program through a competitive, peer-reviewed process, and successful proposals receive support from geospatial technologies experts in both field and lab settings, access to specialized equipment and software, and intensive training opportunities.

this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Planning Grant: Engineering Research Center for Green and Climate Resilient Built Environments (Green CRiB)

Awardee: North Carolina State University

Amount: \$100,000.00

Abstract: the vision of the proposed ERC for green and climate resilient built environments (green cribs) is to enhance the climate-resilience of our society by improving indoor temperature stability as a means of dramatically increasing passive survivability, environmental justice, and providing a pathway to accelerate energy system decarbonization. The Green Cribs ERC planning grant activities will focus on identifying cutting-edge, sustainable, engineering-based innovations in transparent envelope materials and enabling smart manufacturing technologies that will transform how natural and artificial light, heat and energy are managed in the built environment. Window and transparent envelope technologies leveraging innovations in super-insulating materials and novel light management paradigms will enable dramatic reduction of the overall need for active cooling/heating in buildings and agricultural greenhouses, while maximizing access to safe temperatures for both human living and economic activity, including food production. Green Cribs is envisioned as an essential strategy for addressing climate change and environmental equity through energy savings and grid protection, while catalyzing innovation in the \$0.42 trillion glass/window industry and multiple sectors it serves, and training the next generation of diverse, convergence- and innovation-minded engineers to solve complex societal problems. In this ERC, we aim to dramatically improve indoor temperature stabilization against outdoor temperature variations, which will lead to residual load reductions essential for grid decarbonization using an entirely new approach predicated on dynamical management of heat, light and energy at the level of the built environment. A diverse ERC team in terms of expertise, gender, race, geographic location, and career stage will be formed to establish an integrated research, innovation, learning, and mentoring environment with broad participation to produce a highly diverse group of convergent thinkers and problem solvers that reflect the increasing **diversity** of our society. System-level implications on safety, climate resilience, environmental equity and justice, reduction in greenhouse gas emissions and grid decarbonization will be sought and enabled through enabling technologies, fundamental research, smart manufacturing innovations and stakeholder engagement. Intellectual merit

outcomes of this planning grant are to: i) establish linkages between how multi-functional and dynamic transparent envelope technologies and innovations therein will impact climate resilience, energy equity, and grid decarbonization, ii) identify system-level and technology-level testbeds (residential and commercial buildings, greenhouse agriculture, etc.) that will maximize system-level benefits and societal impacts, iii) chart a path towards developing enabling technologies that advance thermal and light management properties well beyond the current state-of-the-art to become responsive to system-level needs, iv) identify critical pathways for advancement of aerogel thermal insulating windows, macroelectronic devices in fundamental areas of reversible electrodeposition, light energy modulation required for optimal plant growth and human comfort, on-glass energy harvesting and storage, and v) improve sustainable, low-cost and large scale manufacturing of advanced technologies on glass and other envelopes. system-level evaluations in primary testbeds in conjunction with stakeholders will be identified to guide research with an eye on minimizing cost and maximizing acceptance, adoption and societal impact. the green cribs planning activities will also seek to identify the broadest possible stakeholder community and foster convergence of diverse disciplines related to systems, technologies and fundamental knowledge. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Planning Grant: Engineering Research Center for Electrosymbiotic Engineering, Design, and Technology (CEED-TECH)

Awardee: Washington State University

Amount: \$100,000.00

Abstract: the center for electrosymbiotic engineering, design, and technology (ceed-tech) will investigate the design rules of recognition, organization, and performance that allow electrochemically active microorganisms to interact with inert electronic materials through a process

called electrosymbiotics. the center seeks to harness bioprocesses through technologies designed to address pressing issues in water security, renewable energy, and green manufacturing. currently, there are knowledge, training, and technical gaps that limit our ability to diversify and scale up these technologies for industrial applications. without multidisciplinary efforts, the field has lagged in the workforce training and diversification that is critical for building productive partnerships, collaborative infrastructure, and large-scale networks between academia and industry that are needed for technology development. this engineering research center (erc) planning grant will bring together a diverse team of scientists, engineers, and relevant stakeholders (academia, industry, and policymakers) and prioritize efforts through in-person and remote planning meetings to develop a full erc proposal. specifically, we will (1) identify key stakeholders for pressing sustainability issues in electrosymbiotic engineering, (2) reach consensus on the significant bottlenecks in advancing electrosymbiotic technologies, (3) refine proposed solutions for developing large-scale electrosymbiotic technologies, (4) build technical and administrative teams, and (5) develop a shared vision across all center participants with a commitment to **\*\*diversity\*\***, equity, and inclusion.

electrosymbiotic engineering is a new field of science that integrates many stem disciplines in engineering and life sciences to actualize technologies critical for economic integration and growth. advancing technology transfer in the field requires a convergent and innovative research and education plan across all science and engineering areas influencing electrosymbiotics and between academia and industry. the center will leverage the **\*\*diversity\*\*** required by this field to create engineering platform designs for market-ready technologies modeled as integrated systems for stable performance and scalability. overcoming the scalability bottleneck will bring transformative electrosymbiotic platforms to the testbed stage. the testbeds will provide integrated environments for problem-solving and new product development. the planned research efforts will be sustained by the targeted and inclusive training program that is needed to develop a workforce with the core competencies, intellectual versatility, and industry knowledge required for long-term professional success and technology implementation. this dynamic and integrated approach will diversify the

economic technology portfolio, promoting growth in 1) sustainable manufacturing, 2) greenhouse gas sequestration, 3) cost-effective wastewater treatment, 4) reclamation of strategically important metals, 5) sensors innovation, and 6) enhanced methods for contaminant removal. industries built on this new center-created knowledge will contribute to our shared economic prosperity and security. this planning grant will allow us to bring together a team of scientists, engineers, and stakeholders to strategically integrate center-driven activities for sustained growth and innovation within the emerging field of electrosymbiotic engineering. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Planning Grant: Engineering Research Center for Electrosymbiotic Engineering, Design, and Technology (CEED-TECH)

Awardee: Washington State University

Amount: \$100,000.00

Abstract: the center for electrosymbiotic engineering, design, and technology (ceed-tech) will investigate the design rules of recognition, organization, and performance that allow electrochemically active microorganisms to interact with inert electronic materials through a process called electrosymbiotics. the center seeks to harness bioprocesses through technologies designed to address pressing issues in water security, renewable energy, and green manufacturing. currently, there are knowledge, training, and technical gaps that limit our ability to diversify and scale up these technologies for industrial applications. without multidisciplinary efforts, the field has lagged in the workforce training and diversification that is critical for building productive partnerships, collaborative infrastructure, and large-scale networks between academia and industry that are needed for technology development. this engineering research center (erc) planning grant will bring together a diverse team of scientists, engineers, and relevant stakeholders (academia, industry, and

policymakers) and prioritize efforts through in-person and remote planning meetings to develop a full  
erc proposal. specifically, we will (1) identify key stakeholders for pressing sustainability issues in  
electrosymbiotic engineering, (2) reach consensus on the significant bottlenecks in advancing  
electrosymbiotic technologies, (3) refine proposed solutions for developing large-scale  
electrosymbiotic technologies, (4) build technical and administrative teams, and (5) develop a  
shared vision across all center participants with a commitment to **\*\*diversity\*\***, equity, and inclusion.

electrosymbiotic engineering is a new field of science that integrates many stem disciplines in  
engineering and life sciences to actualize technologies critical for economic integration and growth.  
advancing technology transfer in the field requires a convergent and innovative research and  
education plan across all science and engineering areas influencing electrosymbiotics and between  
academia and industry. the center will leverage the **\*\*diversity\*\*** required by this field to create  
engineering platform designs for market-ready technologies modeled as integrated systems for  
stable performance and scalability. overcoming the scalability bottleneck will bring transformative  
electrosymbiotic platforms to the testbed stage. the testbeds will provide integrated environments for  
problem-solving and new product development. the planned research efforts will be sustained by the  
targeted and inclusive training program that is needed to develop a workforce with the core  
competencies, intellectual versatility, and industry knowledge required for long-term professional  
success and technology implementation. this dynamic and integrated approach will diversify the  
economic technology portfolio, promoting growth in 1) sustainable manufacturing, 2) greenhouse  
gas sequestration, 3) cost-effective wastewater treatment, 4) reclamation of strategically important  
metals, 5) sensors innovation, and 6) enhanced methods for contaminant removal. industries built  
on this new center-created knowledge will contribute to our shared economic prosperity and  
security. this planning grant will allow us to bring together a team of scientists, engineers, and  
stakeholders to strategically integrate center-driven activities for sustained growth and innovation  
within the emerging field of electrosymbiotic engineering. this award reflects nsf's statutory mission  
and has been deemed worthy of support through evaluation using the foundation's intellectual merit

and broader impacts review criteria.

Title: EVO-LTER: Building collaborations to investigate the effects of urbanization on eco-evolutionary dynamics across the LTER network

Awardee: Rutgers University Camden

Amount: \$99,969.00

Abstract: living organisms are strongly shaped by both ecological and evolutionary forces. because ecological and evolutionary processes are constantly interacting, it can be difficult to fully understand their effects on the biology of organisms. eco-evolutionary dynamics theory provides a powerful framework for understanding interactions between ecology and evolution on contemporary time scales. the long-term ecological research (lter) network, which was launched in 1980 and has over two dozen geographic research sites, has rich historical and contemporary data for many species across a **\*\*diversity\*\*** of biomes. importantly, many lter sites are embedded in urbanizing landscapes, where eco-evolutionary dynamics may be particularly strong. there is a need to bring together scholars with research expertise in urban eco-evolutionary dynamics and lter researchers to (i) integrate lter approaches and the eco-evolutionary dynamics framework in an explicitly urban context, and (ii) train future lter eco-evolutionary dynamics researchers in an integrative science approach. the intention of this project is to develop research initiatives that promote inclusion and equity while advancing the science of ecology and evolutionary biology. two workshops will be hosted to meet these goals. anticipated outcomes include the preparation of several manuscripts that summarize data synthesis activities and outline the future of eco-evolutionary research at lter sites. another outcome is the formation of new hypotheses about the effects of urbanization on eco-evolutionary dynamics across the lter network to stimulate plans for future collaborative and transformative research. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review

criteria.

-----  
Title: Planning Grant: Engineering Research Center for Employment of Persons with Disabilities through Inclusion Engineering (EDIE)

Awardee: Vanderbilt University

Amount: \$99,910.00

Abstract: adults with neurodevelopmental disabilities (e.g., autism spectrum disorder; asd) and/or motor impairments (e.g., multiple sclerosis; ms) have the lowest rates of any type of employment in the us (unemployment rate of 63-68%). the potential economic benefits of improving employment outcomes for these individuals are enormous. for example, the current economic opportunity cost to the us economy of unemployed individuals with asd is estimated at \$90 billion per year, to say nothing of the immeasurable human costs; for individuals with ms, the estimated loss to the economy is approximately \$25 billion per year. this national science foundation engineering research center (erc) planning grant award to vanderbilt university will address this potential by creating the capacity for a future nsf erc for the employment of persons with disabilities through inclusion engineering (edie). edie would seek to create engineered systems to lower barriers to employment for neurodiverse and motor-impaired individuals, such that they can more readily maintain or pursue meaningful employment. to be fully ready for erc scale, we need to more fully develop a number of critical elements through this planning grant, specifically: (1) an erc work plan guided by a 5-year timeline for deliverables that emphasizes (a) stakeholder engagement and assessment of user needs, (b) pilot testing of technologies with and through partner organizations, (c) development of technologies to minimum viable product (mvp) stage, (d) testing through large-scale deployment, and (e) sustainability through commercialization of the technologies. (2) commercialization strategies (e.g., start-ups and licensing agreements) that would create a self-sustained innovation ecosystem. (3) a plan to gradually expand the center's scope to include a

wider range of both technologies and disabilities, consistent with the mission of creating a more inclusive workforce. the proposed vision of the planned edie erc is to create intelligent, adaptive technologies that enable employment and workplace success for individuals with neurodevelopmental and/or motor disabilities, increasing human productivity and economic impact, and leading to a more fully inclusive workforce and society. guiding these engineered systems would be the enabling idea of inclusion engineering, an emerging research paradigm representing the convergence of engineering with implementation science, labor and economic policy, and commercial innovation, toward enabling full societal inclusion of all individuals. multiple technological innovations will need to be pursued in concert toward a truly systems-level solution for full inclusion of motor-impaired and neurodiverse individuals for the future of work. thus, we envision that surrounding and supporting edie's core research thrusts will be an innovation ecosystem that includes commercialization efforts coupled to key stakeholder needs and feedback, a culture of **\*\*diversity\*\*** and inclusion with regards both to center personnel and end-users, and a multi-pronged effort toward developing a future engineering workforce that is trained, equipped, and inspired to advance the future of inclusion engineering. the preliminary convergent research thrusts that we have identified are: (1) workplace disability inclusion and employment nondiscrimination policy to ensure these individual technologies and the resulting engineering systems are based on participatory action research (par) to have real-world uptake and societal impact; (2) social human-machine interaction (shmi) to support neurodiverse individuals; and (3) physical human-machine interaction (phmi) to support motor-impaired individuals. the second and third thrusts map directly into engineered systems, while the first guides them and also addresses issues that are not directly addressable via technological solutions. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Defining research and educational priorities in Near-Surface Geophysics: a workshop and survey in light of the Vision for NSF 2020-2030 Earth in Time report

Awardee: American Geophysical Union

Amount: \$99,892.00

Abstract: human society, and all life of earth, depends on earth's near-surface environment. the soils, water, ground water, microbes, and rock provide resources, allow construction, and shape local environments and their resilience. this is the locus of diverse natural hazards, such as landslides, volcanic hazards, earthquakes, and floods, and persistent soil and water pollution. geoscientists have recently developed a diverse range of techniques to probe and study this environment in increasing detail, to help understand it and improve responses to these hazards and challenges. there is huge potential benefit in integrating these approaches and standardizing and sharing broadly and collectively the diverse data and observations of these studies both for advancing science questions and for immediate societal uses and benefits, for example in planning and resilience to climate change. this proposal will survey the full near-surface research community and support a workshop to plan and develop this integration of approaches, data, and training for the future. this proposal will thus support a recommendation from the national academies on future earth science priorities for nsf outlined in the earth-in time consensus report. high-priority questions about the shallow subsurface (or uppermost ~100 m) of the earth, where lithosphere, hydrosphere, biosphere, and atmosphere meet, could be addressed with integrated near-surface geophysics instrumentation, data, and training. we propose to survey diverse scientists and bring them together in a town hall discussion and virtual workshop series to create and disseminate such an inventory and plan for future integration of diverse approaches and data, including around training to address scientific targets as well as societal needs and challenges while stressing **diversity** and equity broadly. the products of this work would help define the merits, and roadmap, of this integration, including the recommendation of the national academies report earth-in-time for a near surface geophysical center to facilitate integrated near-surface studies. a

goal of the workshop's outcomes is to identify what the near-surface earth science community considers the highest-value scientific research targets as well as provide recommendations to improve education and outreach on near-surface geophysics topics to the geoscience community and related communities such as engineering and those involved in natural hazard mitigation. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Workshops: Broadening Participation of Historically Black Colleges and Universities in the NSF Research Traineeship and Innovations in Graduate Education Programs

Awardee: Jackson State University

Amount: \$99,879.00

Abstract: this award to jackson state university is supported by the national science foundation research traineeship (nrt) and innovations in graduate education (ige) programs. the project team will bring together members of the carnegie doctoral universities high research (r2) historically black colleges and universities (hbcus), experts in graduate education, graduate students, other hbcus, and nsf program officers. two workshops will be organized to address challenges related to increasing the number of stem ph.ds. from underserved populations and providing support and

training to investigators from the participating institutions to generate creative proposals for the nrt and ige programs. the workshops are intended to provide information, understanding, and training on how new graduate models can be created to increase the recruitment, retention, and graduation of minority ph.d. students. this project endeavors to develop strategies and critical recommendations that will address growing national concerns about the number of african americans applying to ph.d. programs in stem. by promoting the close interaction of nsf program officers with a coalition of r2 hbcu graduate education stakeholders, the workshops are intended to increase interest in and awareness of the nrt and ige programs and the number of proposals submitted by r2 hbcu institutions. the specific goals of the workshops are to 1) understand and investigate how to leverage relationships between r2 hbcu institutions and the nrt and ige programs; 2) investigate current models and best practices between the coalition of r2 hbcus that may support recruitment, retention, and positioning of ph.d. stem students into the u.s. workforce, and 3) provide proposal writing training to support the production of competitive proposals to the nrt and ige programs to support these models. additionally, this project will be a path forward to filling in the gaps in outreach to and communications with r2 hbcus by the nsf, which can lead to greater **\*\*diversity\*\*** in the stem fields. the model that results from this project can then be tested and applied to other nsf programs where r2 hbcus are underrepresented in funding. the nsf research traineeship (nrt) program is designed to encourage the development and implementation of bold, new potentially transformative models for stem graduate education training. the program is dedicated to effective training of stem graduate students in high priority interdisciplinary or convergent research areas through comprehensive traineeship models that are innovative, evidence-based, and aligned with changing workforce and research needs. the innovations in graduate education (ige) program is focused on research in graduate education. the goals of ige are to pilot, test, and validate innovative approaches to graduate education and to generate the knowledge required to move these approaches into the broader community. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the

foundation's intellectual merit and broader impacts review criteria.

Title: Creating inclusive workspaces that foster and support BAJEDI leaders in the Big Ten Academic Alliance of geoscientists

Awardee: Ohio State University

Amount: \$99,806.00

Abstract: this award is funded in whole or in part under the american rescue plan act of 2021 (public law 117-2). this project will advance knowledge of the barriers within geoscience academia that prevent the development of \*\*diversity\*\* champions, and help identify strategies to create and sustain cohorts of \*\*diversity\*\* leaders in geoscience at the ohio state university and the wider big ten academic alliance (btaa). the pi will organize a set of convenings of geoscientists with strong engagement from social and behavioral science experts to create and administer institutional climate surveys with an eye towards results-based action plans, developing bajedi faculty leaders in the geosciences, and providing professional development training in bajedi for graduate students and postdocs who will soon be on the job market. studies have demonstrated that \*\*diversity\*\* sparks innovation with underrepresented groups producing higher rates of scientific novelty. yet, there is an innovation-\*\*diversity\*\* paradox because the underrepresented groups that diversify scientific organizations have less successful careers within academia (hofstra et al. 2020). geoscience in particular continues to lag behind other stem fields in creating an inclusive community of diverse scholars. the main objective of this project is the creation of results-based implementation that focuses on training and support of bajedi (belonging access justice equity \*\*diversity\*\* inclusion) leaders at ohio state and the broader big ten academic alliance (btaa). the activities outlined in this project will address two key questions. (1) what barriers exist within geoscience academia that prevent the development of \*\*diversity\*\* champions? (2) what strategies could be employed to create and sustain cohorts of \*\*diversity\*\* leaders to maximize collective impact? this award

reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Planning Grant: Engineering Research Center for Symbiotic Systems

Awardee: Carnegie-Mellon University

Amount: \$99,481.00

Abstract: this planning grant will support efforts to create a new nsf engineering research center on symbiotic systems. symbiotic systems are machines and robotic systems that assist humans with daily tasks in a harmonious manner that does not create unnecessary physical impediments, constraints, or distractions. the purpose of these systems is to improve productivity, mobility, health, and quality of life through the aid of assistive robotics and wearable technologies. an important scientific challenge in developing these technologies is to introduce new types of soft material motors, sensors, and electronics that mimic the properties of natural muscle, skin, and nervous tissue. another challenge is to introduce integrated material architectures, models, and data-driven algorithms that allow these robotic systems to provide active support and motor assistance only when intended by the human user. beyond its potential impact on human well-being, the intelligent symbiotic systems developed by this center also represent opportunities for interdisciplinary scientific education and workforce training as well as broadened inclusion. such opportunities leverage the rich **\*\*diversity\*\*** of stakeholders, societal endeavors, and technical disciplines that relate to human-centered wearable technologies. the proposed erc will establish a scientific and technological framework for creating assistive robotic technologies that will be personalized, dynamically responsive and reconfigurable, and compatible with daily human activity outside of a laboratory or clinical setting. such systems will be *?symbiotic,?* engaging in intimate physical interaction with the body and assisting in rehabilitation, neuromuscular function, disease screening and diagnostics, and therapy without impairing natural bodily function. this will be achieved through

the use of soft material architectures that allow for selective mechanical impedance and actuation along with shape reconfigurability and reversible stiffness tuning. achieving these goals requires the convergence of several disciplines, including materials science and engineering, robotics, medicine, biomechanics, mechanical engineering, human-computer interaction, electrical and computer engineering, human psychology, and artificial intelligence. during the planning phase of this effort, we will pursue the following objectives: (i) identify and engage with stakeholders in research, healthcare, industry, and society to refine the erc vision; (ii) establish partnerships to create a diverse, interdisciplinary team of experts to tackle the various facets of scientific challenges and discovery, technology translation, and societal impact; and (iii) create a framework for workforce training, entrepreneurial activity, and educational outreach to ensure comprehensive and sustainable impact. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: RAPID: Impacts of high magnitude wildfire on volcanic (lava tube) cave water chemistry, nutrient transport, activity and diversity of cave microbiome

Awardee: University of Texas at San Antonio

Amount: \$99,394.00

Abstract: wildfires of high magnitude are known to cause destruction of surface vegetation, soil sterilization, and alteration of soil chemical and hydraulic properties; whereas their effects on subsurface environments are relatively unknown. recent caldwell and antelope wildfires in northern california burnt over hundreds of acres of landscape which included 97% of the area in lava beds national monument (lava beds) that protects volcanic (lava) caves. the volcanic caves provide a unique habitat for bacteria and archaea, and morphologically diverse secondary mineral features (speleothems) in the presence of water. this study investigates the impacts of intense wildfires on volcanic cave ecosystems by sampling cave water and microbial mats, and analyzing them for detailed inorganic and organic chemistry, microbial **\*\*diversity\*\*** and activity. this data from fire-affected caves will be compared with pre-fire data from earlier studies, and the control caves from the unburnt areas, to quantify the changes occurred within the caves due to wildfires. this rapid project supports one minority graduate student at the university of texas at san antonio, a leading hispanic serving institution (hsi) and several undergraduate students (hispanic, minorities, women and first generation). in collaboration with the national park service, the findings of this study will help inform protection of the sensitive natural heritage at lava beds national monument, and important scientific findings will be made available to the visitors of the park. impacts of high magnitude wildfires on surface environments are well documented such as complete destruction of vegetation, soil sterilization, and alteration of physical, chemical and hydraulic soil properties. however, their effects on subsurface environments like vadose zones, shallow aquifers, and caves are relatively understudied. the caldwell fire in 2020 and antelope fire in 2021 in northern california have affected 97% of lava beds national monument (california, usa) landscape that hosts numerous volcanic (lava) caves. volcanic (lava) caves are nutrient-poor, aphotic environments, and yet they

host a rich **diversity** of bacteria and archaea which often utilize reduced energy sources (e.g., reduced iron, sulfur, manganese, or nitrogen compounds) available within the host rock and mineral deposits within the caves. availability of nutrients in caves greatly depends upon the interactions between host rock (basalt) and meteoric water that infiltrates through surface soils into caves through fractured cave walls. this rapid study will obtain water and microbial samples from volcanic caves in wildfire affected and unaffected areas at lava beds, during a post-fire hydrologic response time, and correlate it with chemical and molecular signatures in the samples. post-fire changes in cave water chemistry will be quantified by measuring concentrations of cations, anions, trace metals, and dissolved organic matter, and comparing with pre-fire data from earlier studies, and from control caves. analysis of 16s rna gene sequencing and atp will be used to track changes in microbial **diversity** and activity within the caves during the post-fire period. one graduate student and several undergraduate students from the university of texas at san antonio and university of new mexico will perform samples collection and subsequent laboratory analyses. these results will provide a key information regarding impacts of surface wildfires on subsurface ecosystems. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: TOWARDS A SUSTAINABLE MANAGEMENT OF INSECT COLLECTIONS IN THE U.S. THROUGH THE ENTOMOLOGICAL COLLECTIONS MANAGEMENT WORKSHOP

Awardee: Entomological Society of America

Amount: \$99,000.00

Abstract: natural history collections are an archive of earth's bio**diversity**, informing our understanding of the planet and ecological interactions that impact society. recent global initiatives to digitize biological collections have transformed the scope and scale of how these biorepositories contribute to integrative biological research. interest in collections and their data is increasing,

however much of the workforce capacity remains the same. entomological collections are especially important because insects represent the most diverse and abundant group of animals with over one million known species. insects are ubiquitous in our everyday lives and an essential part of most ecosystems. they are also important to human health, as the majority of plant pollinators, disease vectors, and agricultural pests are insects. collections are organized and maintained only through the specialized knowledge and experience of museum personnel, generally passed directly from one generation to the next, as no formal program has existed to do this across the community. this generational knowledge transfer has been especially important in smaller collections with limited staff, which represent ~70% of all u.s. insect collections. despite their size, these collections are often extremely valuable due to their strong regional holdings. this effort will produce a comprehensive program to provide formal best-practices training, both in-person and online, to collections personnel, as well as providing much-needed networking opportunities for collections workers across career stages and institutions to share their knowledge and experience with the broader collections' community. this award supports the progressive advancement of the entomological collections management workshop series, including virtual participation and material, co-sponsored by the entomological collections network (ecn) and the systematics, evolution, and bio\*\*diversity\*\* (syseb) section of the entomological society of america (esa). the workshops are scheduled to take place annually in summer 2022 to 2024, with hosting rotating between the yale peabody natural history museum, cleveland museum of natural history, and arizona state university. the workshop will be developed as a hybrid virtual and in-person event. during the 3-4 day workshop, participants will receive training in entomological collections management covering a wide range of topics, various topics including policies, specimen handling, curation, conservation, and digitization. this project will encourage the participation of collections staff managers and students associated with smaller collections, as they often have with more limited resources for training and collection development. this workshop will also help fund participation by students and early career researchers, the largest and most diverse (in terms of gender, ethnicity, and

socio-economic background) segment of the collections management community. the professional development opportunities provided by this workshop will thus lead to a more highly skilled and integrative community of collections management personnel. the virtual components of this workshop will be shared to the broader community through the ecn website, with the results of in-person workshops also presented at the ecn annual meetings. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: BEE: IMEMEBA Workshop: Insights from Macro-Ecology and Macro-Evolution for Biodiversity Assessment

Awardee: University of California-Berkeley

Amount: \$98,860.00

Abstract: the earth's ecosystems are under serious threat due to ongoing stressors of the anthropocene. presently, we have no reliable way to assess the overall health of an ecosystem, and the bio\*\*diversity\*\* therein, let alone to identify thresholds of change beyond which a complex ecosystem cannot recover. much needed are insights into how patterns of species \*\*diversity\*\* that we understand to emerge at small scales are propagated up to shape entire ecosystems: what are the drivers, and what aspects impart resilience to perturbations such as those from invasive species or climate change? three rather disparate research areas have started to examine how large scale ecological and evolutionary patterns emerge through time, notably in the context of fossils, where changes in communities can be studied through the geological record; remote archipelagoes in which different ages of component islands can be used as snapshots of community composition through geological time; and microbial systems, where large scale patterns emerge relatively quickly. this project brings researchers from these different disciplines together, along with others who are developing theory focused on emergent patterns that can apply to any or all of these systems. the primary goal is to identify commonalities across systems and build a unified theory that describes large scale patterns of ecosystems and attributes that promote resiliency to change. the outcomes will have broad societal impact for understanding ecosystem response to changing climate. in addition, the workshop will contribute to the training and scholarly advancement of diverse early career investigators. the project has three organizers and an additional six core participants. there will be a preliminary planning workshop held for the core participants. this small workshop will be short and focused, based at blue oak field station, california in fall 2021, and geared towards expanding on concepts at the intersection of the different disciplines and planning for the main workshop. the primary workshop will be held at schoodic, maine and will be longer, larger, and more integrative, tentatively scheduled for june 7-13, 2022. for the main workshop the organizers have identified 30 key participants who are active in developing insights into large scale

ecological and evolutionary properties within each of the fields of paleoecology, island community ecology, and microbial systems, as well as researchers who are developing theory at the intersection of these disciplines. participants have been targeted with an eye to gender equality and **\*\*diversity\*\*** of career stages. for the primary workshop, eight slots have been reserved for applications from graduate students and early career scientists. this workshop was funded through the bridging ecology and evolution category in the biological sciences directorate, division of environmental biology. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Planning Grant: Engineering Research Center for Environmentally Applied Refrigerant Technology Hub (EARTH)

Awardee: University of Kansas Center for Research Inc

Amount: \$98,615.00

Abstract: abstract for planning grant: engineering research center for environmentally applied refrigerant technology hub (earth) part 1: pg: earth will bring together leaders from the research community, industry, and educational institutions to address critical scientific, engineering, workforce development, and policy issues related to the future of refrigeration and air conditioning (rac). rac systems are widespread throughout modern society, enabling transportation of fresh foods, storage of medicines, and cooling of buildings. the u.s. is a global leader in designing and manufacturing rac systems, and the u.s. chemical industry has been a major innovator in creating the hydrofluorocarbon (hfc) refrigerants that replaced ozone-depleting chlorofluorocarbons (cfcs). given that rac now accounts for nearly 20% of worldwide energy consumption, there is an urgent need to develop new and more energy efficient cooling technologies. at the same time, current hfc refrigerants are being phased out due to global warming concerns. there is thus a need to develop

innovative new refrigerants and cooling technologies that are safe for the environment and efficient processes that enable the economical and safe recovery and reuse of millions of kilograms of deployed hfc refrigerants. earth will be a critical national resource to address these challenges. this planning grant will enable stakeholders to assess a variety of important topics impacting the development of alternative refrigerants and novel cooling cycles. innovation in the global refrigerants market is often led by major u.s. companies, but the markets for their products are global and growing rapidly. understanding this global market landscape and developing cutting edge technologies in this space are critical components of earth and will help the u.s. maintain its leadership in innovation and manufacturing in the strategically important refrigerants industry. earth will facilitate the formation of partnerships between educational institutions, industry, national labs, trade groups, and policy makers. the phase down of hfcs over the next two decades is estimated to create 150,000 new jobs and increase manufacturing by \$39 billion in the u.s. while preventing global temperature from rising by 0.5 °c. the erc's foundational components will go beyond research to include technical training and workforce development at all participant stages. it will foster a culture of **\*\*diversity\*\*** and inclusion and create value within an innovation ecosystem that will extend beyond the lifetime of the erc. part 2: the erc we envision will address the basic science, engineering, education, and policy issues that are essential for meeting the many challenges facing the rac infrastructure. three major issues will shape the thrusts of earth. first, the high global warming potential of the current generation of refrigerants (hfcs) is requiring the rac industry to again consider new fluids that balance performance, efficiency, safety, environmental concerns, and a host of other factors. the number of small molecules and their mixtures that could potentially be used in rac cycles is almost limitless, but only a small subset have been synthesized and tested. second, the vast majority of rac systems are based on hundred-year-old vapor-compression technology, but new approaches including solid-state technologies that utilize magnetocaloric, electrocaloric, and mechanocaloric effects could revolutionize the field. third, millions of kilograms of high global warming potential hfcs valued in the billions of dollars are currently in use around the world, and

most consist of azeotropic mixtures. there is currently no means of separating and recovering these valuable compounds. earth will bring together experts in high fidelity experiments, advanced atomistic simulations, data science methods, and process design to develop novel refrigerants, energy-efficient cooling designs, and optimized hfc recovery processes. the core planning group from the university of kansas, university of notre dame, university of maryland, lehigh university, and university of south dakota has the needed expertise and experience to bring together a multi-disciplinary team composed of participants from academia, industry, national laboratories, professional organizations, and policy makers to prepare this proposal. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: MRA: Elucidating Plant and Mycorrhizal Fungal Relationships and Consequences Across Space and Time

Awardee: Smithsonian Institution

Amount: \$98,247.00

Abstract: many plants are dependent on belowground fungi to help them obtain nutrients and respond to environmental stress. revealing the patterns and drivers of these interactions is important for understanding forest ecology and improving management practices. plant-fungal associations in the soil can dramatically influence plant growth and terrestrial ecosystem function. this research will take the advantage of several existing datasets, including those collected by national ecological observatory network (neon) and the u.s. forest service (usfs), to understand: 1) nation-wide patterns of plant-fungal associations; 2) key factors that influence these associations; and 3) how plant-fungal interactions influence key ecosystem functions such as carbon cycling. this research project will contribute to the fields of microbial ecology, ecosystem science, and global change biology by formulating and testing new theories about plant-fungal associations. results of the

project will inform forest managers, policymakers, and other stakeholders on how to improve ecosystem management of plant and fungal bio\*\*diversity\*\* to promote sustainable ecosystems. the project will contribute to the professional development of diverse students at several stages. the goal of this project is to understand the patterns, drivers, and consequences of the linkages between plant and mycorrhizal fungal \*\*diversity\*\* across spatial and temporal scales. this information will enable better predictive understanding of essential ecosystem functions which they control. the project will use a holistic, scale-dependent framework that forecasts the strength and direction of arbuscular mycorrhizal (am) and ectomycorrhizal (em) fungal-plant associations, and provides greater insight about the consequences for ecosystem functioning across space and over time. specific objectives of the project include: 1) elucidation of patterns of plant and mycorrhizal fungal \*\*diversity\*\* across scales by extensive dna sequencing and analysis; 2) determination of key abiotic and biotic drivers of observed co-occurrence patterns; and (3) forecasting the effects of plant-mycorrhizal fungal couplings on tree productivity and soil c storage, two key forest ecosystem functions. by linking multiple facets of both above- and belowground \*\*diversity\*\* in a scale-dependent context, the project will produce robust continental-wide distribution maps of am and em fungi for the first time. leveraging data-rich sampling of putative biotic and abiotic drivers of plant and fungal \*\*diversity\*\* by neon and the usfs, the project will also provide broad-scale understanding of when and where these drivers serve to couple or decouple plant and mycorrhizal fungal \*\*diversity\*\*. finally, by linking plant and mycorrhizal fungal \*\*diversity\*\* to the consequences they have for plant productivity and soil c storage and stability, the project will improve understanding of ecosystem resilience to environmental stress. the project will train diverse undergraduate and graduate students, postdoctoral scholars, and will enhance the development of three early-career scientists. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: LEAPS: Enabling Scientific Societies to Support Inclusive, Diverse, Equitable & Accepting (IDEA) Scientific Environments

Awardee: American Institute of Biological Sciences

Amount: \$96,488.00

Abstract: Scientific institutions increasingly recognize the need to remove barriers for individuals historically underrepresented in science and to improve **diversity**, equity, and inclusion (DEI). A wider breadth of scientific competencies, achieved by improving DEI, is needed to address many critical scientific concerns with global impacts. However, improving DEI requires a significant cultural shift, and scientific societies provide a unique platform to lead these cultural changes in the biological sciences. Scientific societies represent a wide variety of individuals and institutions; they

have access to multiple fields of biology to impart resources and education; and they can enable networking and idea sharing across many disciplines and organizations to empower new approaches. the american institute of biological sciences (aibs) was founded with the goal of unifying the individuals and organizations that collectively represent the biological sciences, so that the community could address matters that impact life on earth. aibs brings together 115 member societies and organizations that represent the full spectrum of the life sciences to address matters of collective concern. it is critical that scientific societies create inclusive, diverse, equitable and accepting (idea) scientific environments to ensure that science is equipped to address 21st century grand challenges. creating idea scientific environments requires an iterative process of top-down and bottom-up approaches that rely on sharing information and experiences, analyzing personal assumptions and expectations, communicating with honesty and openness, and committing to change.

this project will engage and create a collaborative network of majority- and minority-serving biological scientific societies to foster cultural change through two virtual workshops. these workshops will engage scientific society leadership to collaboratively understand the components of idea cultures, assess the current culture in biology, identify barriers to enabling idea environments, create action plans to overcome these barriers, and commit to long-term cultural change. the first workshop will provide a forum for leaders of scientific societies to engage in shared learning, discussion, and reflection on three topics: (1) culture, (2) bias and stereotypes, and (3) equity. the workshop will offer tools for participants to develop action plans to enable idea scientific environments and to take the knowledge, resources, and tools they have gained back to their organizations. a second workshop will occur 6 months later and will be informed by a webinar and a participant survey to assess early implementation of the action plans. the workshop will result in longer-term steps to continue progress in creating idea scientific environments. among the intended project outcomes is a "tool kit," a repository of tools, templates, resources, and other information that will be available to scientific societies, other institutions, and the public. this tool kit will be curated over time as a place to share information and help cultivate the large-scale changes needed

to create idea scientific environments. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Mass transport in Jupiter's magnetosphere -- driven by internal or external processes?

Awardee: Trustees of Boston University

Amount: \$94,720.00

Abstract: the sun emits a stream of particles called the solar wind. the solar system presents a wide variety of obstacles to the solar wind in the form of planetary magnetospheres. magnetospheres arise from the internal magnetic field of a planet and serve to deflect the solar wind from the surface of the planet. mass from the solar wind hits the magnetosphere and is diffused toward the poles and then carried out behind the planet in a structure called the magnetotail. io is a moon of jupiter that also provides particles to its magnetosphere from within, and so it can be used to trace the flow of particles from within the magnetosphere. this project will use observations of sulfur and sodium ions to trace out the diffusion of particles from within jupiter's magnetosphere to better understand the process of diffusion in magnetospheres. the project will use a dedicated telescope for their observations. the project will also create a children's book, 'the misfit telescope' with a companion website and social media stream that use the benefits of \*\*diversity\*\* in scientific instrumentation as a parable to illustrate the benefits of racial and cultural inclusivity. the proposed project will study the io plasma torus (ipt) around jupiter in order to gain insight into the jovian magnetic field. the project will use the io input/output observatory to make time domain observations of s ii and na lines in the ipt to determine the nature of diffusion of material. ioio is a small-aperture robotic coronagraph that operates nightly, contemporaneously recording narrow-band images of the ipt ins s ii. combined with a model of the ipt, the observations will show whether diffusion is driven by mass loading from

io or by activity in the middle jovian magnetic field. the project's children's book will show the value of both being in the minority and havingg a different point of view and of being in the majority and accepting and respecting the minority point of view. the book will be produced by the planetary science institute's award winning public outreach team. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: NSF Postdoctoral Fellowship in Biology FY 2021: Convergent Evolution of Development and Feeding Biomechanics in Weakly Electric Fishes from South America and Africa

Awardee: Ford, Kassandra

Amount: \$93,000.00

Abstract: this action funds an nsf postdoctoral research fellowship in biology for fy 2020, broadening participation of groups under-represented in biology. the fellowship supports a research and training plan for the fellow that will increase the participation of groups underrepresented in biology. the project incorporates multiple scientific fields and examines the concept of "convergent evolution," or similar characteristics in unrelated organisms. this research addresses the lack of clear terminology associated with the term "convergent evolution" by investigating the question: at what point are organisms considered convergent? the fellow will use integrative methods to study two groups of diverse fishes and obtain training across scientific disciplines. this work is important preparation for the fellow's future research program that will be focused on convergent evolution research. the sponsor will provide extensive training on teaching and mentoring so the fellow will be a well-rounded academic with experience with advising, lecturing, and leading students in research projects. the fellow will interact with underrepresented students at all educational levels during the broader impacts activities: k-12 students, stem undergraduates, and graduate students. these efforts address the lack of representation in stem at all levels, to increase the overall \*\*diversity\*\* at

the postdoctoral level and beyond. the fellow will take an integrative and interdisciplinary approach to examining convergence (and its terminology) in two charismatic groups of freshwater fishes. electric fishes, gymnotiformes (south america) and mormyridae (africa), are generally deemed convergent in many ways, including genes, sensory systems, and ecology. previous work showed that while these two groups are indeed similar in these aspects, they are not identical. the project will use methods to quantify head and skull shape, characterize feeding modes, and measure feeding success for comparisons across electric fish species. the results of this work will allow the fellow to understand the degree to which species in these two groups are convergent in developmental processes and/or functional behaviors. the fellow aims to diversify the field of ichthyology through her research, collaborations, and mentorship of underrepresented students. the fellow will mentor undergraduates at a historically black college & university, advise a student during a research experiences for undergraduates project, lead scientific lessons at k-12 schools, and host workshops for graduate students aimed at increasing \*\*diversity\*\* at the postdoctoral level. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Expanding The Capacity Of The Center for Infrastructure Transformation and Education Through Integrating Diversity, Equity, and Inclusion into Infrastructure Education

Awardee: University of Wisconsin-Platteville

Amount: \$92,074.00

Abstract: this project aims to serve the national interest by expanding the capacity of the center for infrastructure transformation and education (cit-e) to support civil, construction, and environmental engineering faculty members in their efforts to integrate \*\*diversity\*\*, equity, and inclusion (dei) into infrastructure education. the causes of inequitable infrastructure are many; however, given its leading role in infrastructure-related education and research, the civil and environmental engineering

(cee) faculty has an obligation to recognize and address the need for systemic change. historically, cee faculty members have not received formal training on dei issues. while such training is becoming more common, a gap remains. this level 1 capacity building project will support cit-e, an existing and thriving community of practice (cop), through providing the foundation for future work in developing a multi-institutional effort to transform the cee education community into a community that can sustain growth in dei integration. the collaborative research project is a joint effort by the university of wisconsin, platteville, lafayette college, colorado state university, and virginia polytechnic institute and state university. with the increased capacity generated by this expanded network and a shared vision, the cit-e cop work will be transformative. leveraging the cit-e and the cop, the project frames the work through the lens of two continua: race neutral/race conscious and inclusion infrastructure/exclusion infrastructure. this project will develop i) cit-e communal understanding of how dei and infrastructure are related; ii) what the interaction among members reveals about dei; iii) how members of the cop can educate one another by addressing dei issues in education, research, and professional practice; and iv) how the cop can inspire real and lasting change. specifically, this project will increase the capacity of cit-e through the following project objectives: i) gather evidence by compiling a list of non-normative examples of successful institutional efforts that positively impact dei; ii) assess cit-e resources and needs via asset mapping; iii) evaluate community of practice as an appropriate change theory; iv) recruit additional stakeholders and organizations to cit-e based on the gaps identified in previous project objectives; v) identify, cluster, and prioritize ways of integrating dei into cee education using group concept mapping (gcm); and vi) provide the foundation for developing a multi-institutional effort to transform the cee education community into a community that can sustain growth in dei integration. the research team will ensure that key stakeholders, including experts in change theory, dei strategies, and curriculum development are invited to provide external peer review of the project. the research team will facilitate working sessions to address larger tasks such as gcm and asset mapping. through a collaboration with the institute for research in the social sciences (iriss), the project will i)

build the capacity of the geographically-dispersed research team by accelerating the team's integration to operate as a highly-functioning team and ii) explore how team science might add value to efforts to expand the work. the nsf iuse: ehr program supports research and development projects to improve the effectiveness of stem education for all students. through the institutional and community transformation track, the program supports efforts to transform and improve stem education across institutions of higher education and disciplinary communities. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Linguistics: Reconstructing the Discipline through Universals Research

Awardee: Philadelphia Area Center for History of Science

Amount: \$91,674.00

Abstract: this project is a historical investigation of modern linguistics, embracing anthropological and cognitive traditions in the discipline. linguistics is strikingly heterogeneous, consisting of sub-fields that touch on almost every aspect of human life?from the study of human genealogy to the development of twentieth-century computer science. accordingly, there are few comprehensive accounts of the discipline, a gap that this project will help to fill. as contemporary society is grappling

with questions about who should have the authority to research and manage human **diversity**, there is an urgent need to understand the tension between particular and general approaches at the heart of linguistics, rather than focusing exclusively on one or the other. funding will support archival visits, conference participation, and translation services, and it will lead to the production of a book, scholarly papers, teaching materials, and community development initiatives that will shed light on the stakes and scope of linguistics as a discipline. correspondingly, the project will give practicing linguists historical insights that may inform policies around the preservation of linguistic **diversity**.

two prominent, yet mutually isolated, research programs dedicated to language universals emerged during the 1960s. one was empirical, and associated with joseph greenberg; the other was logical, with noam chomsky at the fore. drawing on archival materials at stanford university and the massachusetts institute of technology, this project will characterize these two programs in full. it will use them to reconstruct a maximally inclusive history of modern linguistics via patterns of citation, collaboration, and subsequent engagement. through the prism of language universals, it will survey major schools and developments in the history of modern linguistics including structuralism, machine translation, typology, and transformational-generative grammar. informed by recent work in science and technology studies concerned with the nature and historicity of data, research praxis, scientific communication, and the organization of knowledge, the project will promote understanding of the processes by which modern disciplines have taken shape and defended their societal relevance over time. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: PPOSS: Planning: A Disciplined Approach to Scaling in the Post-Moore's Law Era

Awardee: Northwestern University

Amount: \$91,300.00

Abstract: general-purpose processor speeds have not increased at their historical rates for over 15 years. designers have instead offered scalable computing systems with additional barriers to realizing the performance gains that once came "for free" with each processor generation. this situation has slowed the progress of all endeavors that involve scalable computing. a disciplined approach to reversing this trend must start and end with a direct engagement with the scalable-system users and programmers faced with these barriers. with this goal, the investigators are performing in-depth face-to-face interviews with a broad set of users. in addition, with these users, the project team is also examining codes, exchanging ideas, and offering assistance. this is producing a deep understanding of how users are coping with their growing demands for computing while computing is placing more demands upon them. the project's novelties are this in-depth study and the resulting formulation of an approach to address the limitations of scalable computing based on real users' needs. the project's impacts are the dissemination of the survey results and a recommended approach forward that restores meaningful layers of abstraction to scalable systems, freeing programmers from being drawn deeper into the complexity of scalable computing while delivering higher performance to them. the investigators performed a similar study in 2011. with this planning grant: (1) they are conducting a more ambitious study with a greater **\*\*diversity\*\*** of subjects. by re-engaging as many 2011 subjects as possible, this becomes a longitudinal study capable of revealing trends not visible in any single point-in-time study. (2) the investigators are using these interactions to explore transitioning their foundational work to practice, to build a larger team, and to expand the scope of future work. the results of the 2011 study inspired the

investigators to produce breakthroughs in speculation, dependence handling, latency tolerance, and automatic parallelization. the 2021 study serves as a vehicle to explore ways to transition these results to practice. (3) the investigators believe that hardware can be more domain-adept without being domain-specific. using prior insights, they are exploring hardware/software concepts that deliver top performance levels without undue programmer burden. by testing these ideas in the context of the study, the investigators can best frame the problem, refine approaches, and test hypotheses in the context of actual needs, opportunities, and constraints. all of these activities ensure that future work in scalable systems will have greater impact. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Proposal for a SUMMIT to Plan a Conference Workshop for Minoritized Geoscientists

Awardee: University of California-San Diego Scripps Inst of Oceanography

Amount: \$90,866.00

Abstract: this project aims to host a four-day summit with fifteen leaders from geoscience organizations with a demonstrated interest in improving belonging, accessibility, justice, equity, **\*\*diversity\*\***, and inclusivity (beajedi). the summit will provide these leaders with opportunities to share successful strategies for improving beajedi in geoscience. leaders at the summit will design a conference where ~100-300 geoscientists network, present their research, and share successful strategies for improving beajedi in geoscience. the summit will thus begin the process of increasing interagency and interpersonal sharing, design, and refinement of the strategies used to strengthen beajedi in geoscience. the main goal of this project is to host a four-day summit with 15 leaders from the largest and or influential geoscience organizations with a demonstrated interest in improving belonging, accessibility, justice, equity, **\*\*diversity\*\***, and inclusivity (beajedi) in

geoscience. summit participants will collaboratively design a conference workshop while sharing successful strategies for improving beajedi for geoscientists of color. this designed workshop will be primarily attended by geoscientists and will allow attendees to present research and network. the workshop will also include surveying and interviewing attendees to collect information that are germane for successfully recruiting and retaining people of color within geoscience. the questions that the surveys and interviews seek to answer are: 1. what attracts people of color to geoscience? 2. what are the experiences of geoscientists of color? 3. what do full belonging, accessibility, justice, equity, **\*\*diversity\*\***, and inclusivity look like to geoscientists of color? alongside developing a novel method of answering the questions listed above, this project's broader impacts are strengthened by including a mentorship component. the summit will pair early-career researchers interested in beajedi issues with established and experienced individuals. the early-career researchers will gain conference proposal writing experience while expanding their network. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: 3 Myr of Laurentide Ice Sheet History Inferred from Cosmogenic Nuclides in Ice-Rafted Debris

Awardee: University of Vermont & State Agricultural College

Amount: \$88,394.00

Abstract: the laurentide ice sheet over north america caused large changes in climate and sea level as it grew and shrank over ice age cycles during the past three million years, but little is known

about the ice sheet's detailed history throughout this interval. this project will determine how big the ice sheet was through time using chemical markers in layers of sand on the seafloor that melted out of icebergs drifting from north america. this method provides a new way to learn about past changes in the laurentide ice sheet and test ideas for how climate change and ice sheets affect each other. the results should help with predictions of sea-level rise far into the future due to global warming and melting polar ice sheets. this project will also educate and involve a wide range of people in climate science in several ways. videos about the research will be sent to boston public schools through the bostem organization to help students in the area learn about careers in science. the researchers will participate in activities through the mcauliffe center for integrated science learning at framingham state university to teach middle and high school students and teachers about climate change. college students will help with the research during summers through the integrated science for society nsf research experience for undergraduates at boston college, which tries to find students from underrepresented minority groups or who are the first in their family to go to college and that do not have research possibilities at their school. lastly, the project will support a female ph.d. student already at boston college and an m.s. student at the university of vermont.

the laurentide ice sheet over north america was one of the largest drivers of climate and sea level over the ice age cycles of the past three million years, but its history over this interval is shrouded in uncertainty largely due to limitations of conventional geologic records. this project will take a new approach, measuring the concentrations of rare chemicals in quartz sand layers from ocean sediment cores that melted out of drifting north american icebergs. the chemistry of the sand reflects the history of north american ice sheet cover because the chemicals accumulate in land surfaces exposed to the atmosphere but radioactively decay away when the surfaces are buried by ice. four sediment cores will be analyzed to reconstruct long-term laurentide ice sheet evolution, and analyses of sand samples collected across eastern canada will show how their chemistry records ice sheet variations over the most recent ice age cycle. together with similar reconstructions produced over the past five years from greenland and antarctica, these records will provide a comprehensive picture of how

these three ice sheets varied in the past and contributed to global sea level. the results will offer much-needed constraints to test theories and models of paleo-ice sheet change, useful for improving long-term future projections of ice sheets on earth today. this project will increase literacy and **diversity** in climate science in multiple ways. ?science bites? videos about the research will be distributed to boston public schools through bostem to demystify careers in science. participation in ongoing efforts through the mcauliffe center for integrated science learning at framingham state university will help educate middle and high school teachers and students on climate change. this project will support an existing female ph.d. student at boston college and an m.s. student at the university of vermont. summer undergraduate research assistants will be recruited through the integrated science for society nsf reu at boston college, which seeks to attract underrepresented minority and first-generation college students from schools with limited research opportunities. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Expanding The Capacity Of The Center for Infrastructure Transformation and Education Through Integrating Diversity, Equity, and Inclusion into Infrastructure Education

Awardee: Virginia Polytechnic Institute and State University

Amount: \$87,045.00

Abstract: this project aims to serve the national interest by expanding the capacity of the center for infrastructure transformation and education (cit-e) to support civil, construction, and environmental engineering faculty members in their efforts to integrate **diversity**, equity, and inclusion (dei) into infrastructure education. the causes of inequitable infrastructure are many; however, given its leading role in infrastructure-related education and research, the civil and environmental engineering (cee) faculty has an obligation to recognize and address the need for systemic change. historically, cee faculty members have not received formal training on dei issues. while such training is

becoming more common, a gap remains. this level 1 capacity building project will support cit-e, an existing and thriving community of practice (cop), through providing the foundation for future work in developing a multi-institutional effort to transform the cee education community into a community that can sustain growth in dei integration. the collaborative research project is a joint effort by the university of wisconsin, platteville, lafayette college, colorado state university, and virginia polytechnic institute and state university. with the increased capacity generated by this expanded network and a shared vision, the cit-e cop work will be transformative. leveraging the cit-e and the cop, the project frames the work through the lens of two continua: race neutral/race conscious and inclusion infrastructure/exclusion infrastructure. this project will develop i) cit-e communal understanding of how dei and infrastructure are related; ii) what the interaction among members reveals about dei; iii) how members of the cop can educate one another by addressing dei issues in education, research, and professional practice; and iv) how the cop can inspire real and lasting change. specifically, this project will increase the capacity of cit-e through the following project objectives: i) gather evidence by compiling a list of non-normative examples of successful institutional efforts that positively impact dei; ii) assess cit-e resources and needs via asset mapping; iii) evaluate community of practice as an appropriate change theory; iv) recruit additional stakeholders and organizations to cit-e based on the gaps identified in previous project objectives; v) identify, cluster, and prioritize ways of integrating dei into cee education using group concept mapping (gcm); and vi) provide the foundation for developing a multi-institutional effort to transform the cee education community into a community that can sustain growth in dei integration. the research team will ensure that key stakeholders, including experts in change theory, dei strategies, and curriculum development are invited to provide external peer review of the project. the research team will facilitate working sessions to address larger tasks such as gcm and asset mapping. through a collaboration with the institute for research in the social sciences (iriss), the project will i) build the capacity of the geographically-dispersed research team by accelerating the team's integration to operate as a highly-functioning team and ii) explore how team science might add value

to efforts to expand the work. the nsf iuse: ehr program supports research and development projects to improve the effectiveness of stem education for all students. through the institutional and community transformation track, the program supports efforts to transform and improve stem education across institutions of higher education and disciplinary communities. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Population Dynamics in Random Environments: Theory and Approximation

Awardee: Texas A&M University

Amount: \$85,829.00

Abstract: this project will formulate and analyze a general mathematical framework to facilitate understanding the persistence and extinction of species affected by random environmental fluctuations. global climate change models predict increasing temporal variability in temperature, precipitation and storms in the next century. random environmental fluctuations have been shown to drive populations extinct, promote persistence, change genetic **diversity**, and modify the spread of infectious diseases. it is therefore urgent to develop tools for understanding the effects of random temporal fluctuations in environmental conditions on species. the pis will develop mathematical theory, in conjunction with analytical and numerical approximation methods, to help theoretical ecologists pinpoint how environmental fluctuations affect the long-term dynamics of ecological communities. in collaboration with the gore lab at massachusetts institute of technology the pis will test theoretical results by comparison with microbial ecology experiments. the investigators plan to involve high school and undergraduate students in projects allowing them to develop programming skills and diversify their mathematical and ecological knowledge. for outreach, the investigators will organize seminars and conferences and promote the participation of women and members of traditionally underrepresented minorities within the sciences. the pis will investigate continuous and discrete time models of interacting populations that experience random temporal environmental variations. in the continuous time setting the research will focus on piecewise deterministic markov processes - processes that switch between different systems of ordinary differential equations at random times. in the discrete time setting stochastic difference equations will be analyzed. new methods for checking when species persist and converge to their invariant probability measures (which describe the 'random equilibria' of subcommunities of species) will be developed, and

conditions under which species go extinct exponentially fast determined. since all theoretical models are merely approximations of natural systems, the pis will study how the persistence/extinction results change under small, density-dependent, perturbations of the model parameters. the extinction/persistence criteria will involve lyapunov exponents, which usually cannot be computed explicitly. in order to resolve this issue analytical and numerical approximation methods for estimating the lyapunov exponents will be developed. finally, together with the gore lab at massachusetts institute of technology, the pis will run experiments in order to see how analytical results qualitatively compare with multi-species microbial systems under environmental fluctuations. this project is jointly funded by the division of mathematical sciences mathematical biology program the established program to stimulate competitive research (epscor). this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: LightningBug, An Integrated Pipeline to Overcome The Biodiversity Digitization Gap

Awardee: University of Florida

Amount: \$84,226.00

Abstract: insects are the largest and most diverse class of animals on our planet where they play essential roles in ecosystems and the services those provide to society. entomologists have long been engaged in collecting, preserving and depositing nearly one billion insect specimens at natural history museums around the globe. these collections form the basis for much of our knowledge about insects and provide critical information about the past from which scientists can assess current and future global change impacts. to fully realize the value of these collections, data from insect specimens must first be digitized. however, their small size, delicate structures, and traditional storage and labeling methods creates enormous challenges for large-scale digitization.

consequently, at present, only 5% of specimens have transcribed labels and less than 1% of specimens are imaged. the lightningbug project will break through this digitization bottleneck by establishing a semi-automated workflow involving advancements in robotic multi-view imaging, information extraction and 3d reconstruction. results from this work will provide researchers with the unprecedented capability to capture specimen metadata representing time, place and taxonomic identity along with accurate three-dimensional surface morphology representing color and shape. we expect lightningbug and related technologies will promote ecomorphological studies at a scale that has not been possible to date. the lightningbug project seeks to create an end-to-end pipeline for high-throughput data acquisition from pinned insects in entomological collections. to accomplish this goal, we will: (1) further develop an existing hardware and software platform to capture multi-view imagery of both labels and specimens; (2) build robust algorithms to automatically process fragmentary views of multiple labels into separate integrated "virtual labels;" (3) connect virtual labels to structured text extraction services; and (4) apply photogrammetric analysis to assemble the 3d shape and structure of specimens. guided by real-world science use cases that highlight the use of specimen-based multi-view imaging in studies of global change and functional morphology, the entomological collections of the yale peabody museum and the harvard museum of comparative zoology will be used in rigorous test-case implementations. results will include robust sets of annotated multi-view images, 3d models of specimens (point clouds, textured meshes), 2d reconstructed "virtual labels" and digitized specimen metadata generated from those labels. these digital specimens will present new challenges for data preservation and access, but they will also catalyze new solutions for large-scale storage and delivery of research imagery. this challenge will be addressed via a partnership with morphosource to develop a linked institutional repository model for data access to large digital assets such as those produced by multi-view imaging. ultimately, the ability to capture multi-view image suites and generate virtual specimens at scale will permit new avenues for remote access to research resources, and enable the application of computer vision and machine learning to trait identification and evolution, species recognition and new species

discovery. label data from pinned insects will give researchers access to critical temporal and geospatial information necessary for relating changes in bio\*\*diversity\*\* to other biotic and environmental variables. it will also provide collections staff with a complete digital portrait of their holdings, which can enable historical research, streamline collections use and tracking, and improve data quality control. results from this project will also have applications beyond the natural history collections and research communities, such as computer graphics, product imaging, motion pictures, 3d animation, virtual and augmented realities, and education. more information and results from this project can be found at <http://lightningbug.tech> this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Building consensus around the quantification and interpretation of Symbiodiniaceae diversity

Awardee: Trustees of Boston University

Amount: \$82,230.00

Abstract: single-celled microorganisms are highly diverse and play various roles in the function of natural ecosystems, but it is challenging to recognize how genetic, morphological, and physiological \*\*diversity\*\* relate to each other in microbial groups. in an exemplary case, micro-algae in the family symbiodiniaceae comprise many species that can only be distinguished using molecular data. symbiodiniaceae function as symbionts of various marine invertebrates, but are perhaps best known as the key to coral reef ecosystem health and persistence. the team is hosting a virtual workshop in august 2021 to identify and build further consensus among experts regarding the assessment of symbiodiniaceae \*\*diversity\*\*. by formalizing consensus approaches and disseminating them broadly, this workshop is creating a more collaborative and welcoming research community and ensuring that all current researchers, as well as those entering the field, feel confident applying for

grants, conducting research, and publishing papers that incorporate work on symbiodiniaceae **\*\*diversity\*\***. this workshop is defining additional forward-thinking research priorities that anticipate methodological advances over the next 5-10 years. resolving the molecular **\*\*diversity\*\*** of microorganisms is a major technical challenge, particularly for dinoflagellates in the family symbiodiniaceae. these micro-algal endosymbionts that associate with corals and other marine invertebrates feature massive genomes, high repeat content, and other unique aspects that have hindered their molecular characterization. as sequencing technologies have advanced, so too has our understanding of symbiodiniaceae **\*\*diversity\*\***, which has grown from the presumption of one widespread species in the 1960s to now encompass fifteen divergent genera and likely hundreds of species. this process of discovery has been fraught with controversy, as the most useful phylogenetic marker?the hyperdiverse internal transcribed spacer 2 (its2) region?is frustratingly difficult to interpret in a consistent manner. the ribosomal array is multicopy, it evolves at different rates in different lineages, and it is subject to concerted evolution, all of which complicate phylogenetic reconstructions. moreover, sampled coral tissues contain populations of symbiont cells that can potentially be from multiple symbiodiniaceae taxa, complicating efforts to characterize partner specificity. early debates focused on the extent to which unique its2 sequences indicated the presence of multiple symbiont species or simply multiple intraspecific variants. this central conflict has led to different schools of thought about how flexible coral-algal associations can be, and how they might respond to ongoing climate change. next-generation sequencing has provided more data, but the same foundational interpretive issues remain. this team is gathering pioneering symbiodiniaceae experts from around the world (ranging from seasoned veterans to newly-minted phds) who all collectively agree that a consensus interpretive framework can and must be identified and advanced in order to move the field forward. the participants are generating a ?consensus road map? leading to two workshop products: 1. an nsf white paper; and 2. an open-access, peer-reviewed manuscript. through pre-workshop surveys, four workshop sessions, post-workshop collaboration, and publication, the team is summarizing current practices and recommending key

methods for identifying and analyzing symbiodiniaceae genetic **\*\*diversity\*\*** across three ?umbrellas?: 1. communities, 2. populations, and 3. strains. the written products from this workshop are being distributed to the wider reef and conservation community by leveraging a separate mini-workshop previously developed for the 2022 international coral reef symposium. workshop participants are also highlighting new technologies and research priorities for the next decade that should help fill some of the remaining knowledge gaps. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: RCN-UBE Incubator: Course-based Undergraduate Research Experiences for Students Underrepresented in Biology

Awardee: Edward Waters College

Amount: \$75,000.00

Abstract: the goal of this project is to establish multi-faceted course-based undergraduate research experiences in cellular genetics and socio-biology for students underrepresented in biology. community colleges serve almost half of the undergraduates in the u.s., including many minority low-income, first-generation, and underrepresented students, and many of these students are pursuing careers in biology. in this rapidly changing field, it is important that community college faculty have up-to-date teaching materials that reflect the most recent discoveries in biology and innovative data-analysis approaches. this network will bring appropriate teaching materials and offer professional development with the goal of incorporating cutting-edge biology research and high-impact teaching practices to improve student outcomes. empowering community college faculty to increase student success will have a significant impact on the qualifications and **\*\*diversity\*\*** of the science and technology workforce. this project will take place at edward waters college, distinctively the state of florida's first independent institution of higher learning as well as florida's first institution established for the education of african americans. the wide-spread use of dna sequence data to enhance biological understanding, brings unique challenges for biology educators.

skills from computer and data sciences have become core competencies for students even though many biology faculty completed formal training without the computational expertise needed to effectively engage in this field. this network will bring together members of omics ((proteomics, transcriptomics, metabolomics)) education networks, leveraging their combined expertise to identify and curate common analysis tools, associated curricular and assessment materials, and faculty training strategies to facilitate the adoption of omics instruction. by making existing resources accessible, the network will enable current faculty to guide undergraduate biology students participating in authentic research projects. such work will enhance the ability of students to become productive members of the technological work-force, to succeed in post-graduation studies in biology and related disciplines, and to be better informed citizens and decision makers. the network will develop a consensus set of vetted resources and training materials to be disseminated to the education community through a single web portal for use in undergraduate classrooms. the network will also advance preparation of adjunct biology faculty and recruitment of future junior faculty, who might not otherwise have the opportunity to build relationships with tenured faculty around the country. this project is being jointly funded by the directorate for biological sciences, division of biological infrastructure, and the directorate for education and human resources, division of undergraduate education as part of their efforts to address the challenges posed in vision and change in undergraduate biology education: a call to action (<http://visionandchange/finalreport/>). this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: EAGER: Collaborative Research: Development of an Energy-Harvesting Real-time Under-ice Monitoring System in the Arctic Ocean

Awardee: University of Alaska Fairbanks Campus

Amount: \$75,000.00

Abstract: the arctic is home to some four million people comprising a diverse range of cultures and an economy worth about \$230 billion annually. with global concerns spanning climate change, energy resources, freshwater supplies, and sustainable economic growth, the arctic has sparked intense research and public interest. international efforts to establish sustained arctic observing systems, especially for long-term arctic ocean monitoring with near-real-time data transfer, are urgently needed. the harsh and remote conditions constraining year-round observation sites present significant logistical challenges and energy needs for sustained arctic observations. in addition, monitoring of the arctic ocean using bottom-anchored stationary platforms is limited by a lack of real-time communication between the sensors deployed and arctic operators. the ultimate goal of this project is to develop new energy harvesting and communication solutions so that it is feasible to have a real-time under-ice monitoring system in the arctic ocean. this eager project tests the capacity to address three key challenges, including sustainable power supply through energy harvesting, near-real-time data communication under the sea ice, and survivability under harsh environmental conditions. specifically, the project aims to develop novel techniques to harvest ultra-low-speed oceanic current energy using a two-level diffuser augmented turbine and a novel transverse flux generator. the harvested energy will be used to support sensors and power a novel real-time communication system through the sea ice. the proposed communication system adopts a novel antenna design that overcomes seawater attenuation effects on radio waves and creatively leverages satellite protocols to ensure the under-ice communication unit can transmit observational data to satellites. the project also explores techniques to enhance the survivability of the under-ice monitoring system, such as robust material choice and ice ridge/keel detection and avoidance systems and extends science and engineering education among k-12 and phd-level students in arctic research with an emphasis on **\*\*diversity\*\*** including female and underrepresented students. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Awardee: Texas A&M University-San Antonio

Amount: \$74,208.00

Abstract: research has shown that under-served students typically have few opportunities to engage in high-impact research activities and that first-generation college students want their learning to be connected to their home communities. when educators attempt to improve upon undergraduate research opportunities they frequently focus on placing only select students in one-on-one faculty mentored research and fail to link the research to the students' daily lives. all students should have an opportunity to participate in research in ways that make explicit connections between the content, process, and application of research, or they risk not being able to see the relevance of biological science to their own lives. this rnc-ube incubator network will remove these barriers by developing course-based opportunities for students to engage with real-life data sets provided by regional organizations whose work is informed by biological research. therefore, all students taking introductory biology courses will build research skills within a socially meaningful and applied community context. furthermore, by participating in the course-based research modules developed by this regional network, students will gain a greater understanding of job market \*\*diversity\*\* as it pertains to skills gained during biological research. this network brings together educators from different universities, community colleges, as well as research scientists from an urban health department, a nationally recognized primate research center, and a major regional river authority

tasked with ecological stewardship. the network members will participate in workshops designed to develop course-based undergraduate research experiences (cures) which will be implemented as pilot modules in introductory biology courses. workshops will also identify alignment of modules with core curriculum learning objectives, community partner needs, and potential barriers to implementation. during the pilot cure modules students will collect and analyze data sets on the prevalence and disparities of heritable genetic disorders, diabetes, cancer or environmental threats to the community, many of which disproportionately burden the network?s predominately hispanic population. this rcn-ube incubator will increase collaborative research among students, academia, industry, and community civic services and thus enhance the **\*\*diversity\*\*** of the future stem workforce. students participating in the modules will develop skills in science communication by sharing their results with public groups, family members and network representatives. the impact of the network will extend beyond students and faculty to include members of the community who might otherwise have limited exposure to scientific research, thereby nurturing positive attitudes towards biological research and increased engagement and support of family members with their children?s stem education. this project is being jointly funded by the directorate for biological sciences, division of biological infrastructure, and the directorate for education and human resources (ehr), division of undergraduate education as part of their efforts to address the challenges posed in vision and change in undergraduate biology education: a call to action (<http://visionandchange/finalreport/>). this project is also supported by the nsf hsi and iuse:ehr programs. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Biocultural Heritage and Social-Ecological Resilience

Awardee: Esbach, Michael

Amount: \$74,000.00

Abstract: this award was provided as part of nsf's social, behavioral and economic sciences postdoctoral research fellowships (sprf) program. the goal of the sprf program is to prepare promising, early career doctoral-level scientists for scientific careers in academia, industry or private sector, and government. sprf awards involve two years of training under the sponsorship of established scientists and encourage postdoctoral fellows to perform independent research. nsf seeks to promote the participation of scientists from all segments of the scientific community, including those from underrepresented groups, in its research programs and activities; the postdoctoral period is considered to be an important level of professional development in attaining this goal. each postdoctoral fellow must address important scientific questions that advance their respective disciplinary fields. under the sponsorship of dr. joão biehl at princeton university and dr. flora lu at the university of california, santa cruz, this postdoctoral fellowship award supports an early career scientist examining the mechanisms through which indigenous governance and stewardship fosters social-ecological resilience. in numerous locations and contexts, indigenous institutions and cultural practices have resulted in positive environmental outcomes, such as promoting biological **\*\*diversity\*\***, maintaining ecosystem services, and curbing deforestation. these outcomes are important globally because indigenous peoples manage over 25 percent of the world's land surface. this study explores these dynamics through a partnership with indigenous communities, where accelerating deforestation and degradation, linked to resource extraction and urbanization, threaten their health, well-being, and sovereignty. through a combination of ethnographic, human ecological, and spatial methodologies, this research will examine the connections between indigenous biocultural heritage, institutions, and cultural values and their ecological impacts. a robust communication strategy ensures that results will inform both academics and the general public about how indigenous practices build resilience and support conservation. interdependent relationships over millennia between humans and their surroundings gave rise to a **\*\*diversity\*\*** of indigenous territories across the planet. drawing on rich biocultural heritage, indigenous peoples have developed sophisticated institutions that simultaneously maintain ecosystem services and

relationships with territory. this study investigates features of biocultural heritage, including the knowledge, innovations, and practices used by indigenous peoples to gauge, interpret, and respond to internal and external feedbacks, transmit knowledge, and adapt to changing social, environmental, and political contexts. how do indigenous peoples utilize their biocultural heritage in this manner, what limitations do they face in doing so, and why? this research will address such questions by leveraging a long-term partnership, where threats such as climate change and extractivism represent a microcosm of those impacting the broader region. a multi-methods approach (quantitative, qualitative, ethnographic, participatory) will support an examination of the coupling, decoupling, and potential for recoupling of biocultural heritage with specific territories. results from this research will describe how diverse threats impact the resilience of indigenous territories, and support how we theorize and understand territory. this work will contribute to the fields of human ecology, landscape ecology, land education, and social-ecological systems theory. more broadly, this research will support biological and cultural conservation by highlighting the importance of diverse indigenous values and approaches, and inform the on-going production of a participatory planning instrument for territorial governance. the project also builds local capacity, training, and mentoring by including indigenous researchers. finally, the project has built in mechanisms for research dissemination, for academic and policy audiences, including engaging media sources to broadly communicate research findings. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Belmont Forum Collaborative Research: Pacific Ocean Pathways in Support of Sustainable

Development: An Integrated Approach

Awardee: University of Maryland Center for Environmental Sciences

Amount: \$71,421.00

Abstract: this award provides support to u.s. researchers participating in a project competitively

selected by a 55-country initiative on global change research through the belmont forum. the belmont forum is a consortium of research funding organizations focused on support for transdisciplinary approaches to global environmental change challenges and opportunities. it aims to accelerate delivery of the international research most urgently needed to remove critical barriers to sustainability by aligning and mobilizing international resources. each partner country provides funding for their researchers within a consortium to alleviate the need for funds to cross international borders. this approach facilitates effective leveraging of national resources to support excellent research on topics of global relevance best tackled through a multinational approach, recognizing that global challenges need global solutions. this award provides support for the u.s. researchers to cooperate in consortia that consist of partners from at least three of the participating countries. the teams will establish transdisciplinary networks to develop innovative solutions for sustainable development pathways and seek to assess the positive and negative inter-linkages between the economy, technology, institutions with the environment, climate, bio\*\*diversity\*\*, and human well-being to understand potential pathways to a sustainable world. this project seeks to establish cost-effective, efficient, and sustainable transdisciplinary processes, methods and networks to assist stakeholders, scientists, public officers and citizens of the pacific islands to share common objectives and actions to achieve environmental sustainability. the project will build a network focusing on two pilot sites, fiji and new caledonia. the project will examine the impacts of climate change and other stressors on the ocean environment and ecosystem services. the team will investigate the consequences of these impacts on the environment, society, and economy, to develop sustainable and complementary pathways for future development and sustainable ocean stewardship. these pilot sites will create the framework and methodology and serve as a guide for application and adaptation to other interested pacific island countries. pacpath will integrate a broad range of existing data sets, generate new data sets, and develop new, locally relevant products that will rely on freely available sources such as from the copernicus marine service. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the

foundation's intellectual merit and broader impacts review criteria.

Title: LEAPS: A Diversity, Equity, and Inclusion Workshop at the Joint Aquatic Sciences Meeting

Awardee: Western Washington University

Amount: \$70,532.00

Abstract: scientific societies play an important role in engaging young scientists and creating opportunities that lead to stem careers. because of this role, these societies can help the nation increase the participation of students of color and other underrepresented groups in science and science careers. at the same time, scientific societies also present barriers to inclusion because their leadership, policies and practices have solidified over decades without consideration of the need to be inclusive and welcoming of underrepresented groups. this project develops a process to begin to examine the practices, procedures, and policies within scientific societies that may create an atmosphere of non-inclusivity, non-engagement, and an unfriendly environment for underrepresented groups. an inclusivity, **\*\*diversity\*\***, equity, and access (idea) audit tool will be developed for the consortium of aquatic science societies (cass), an affiliation of nine scientific societies (american fisheries society; association for the sciences of limnology and oceanography; coastal and estuarine research federation; freshwater mollusk conservation society; international association for great lakes research; north american lake management society; phycological society of america; society for freshwater science; and the society of wetland scientists), the majority of whom work in the biological sciences. the idea audit tool will be constructed to be able to identify (1) policies and procedures that perpetuate status quo culture, policies, and procedures (2) specific barriers to broadening participation to diverse populations, specifically black and indigenous people of color, communities from tribal colleges, and historically black colleges and universities, and (3) practices and programs that have been successful within the cass societies. leaders from the cass member societies will engage with leaders from societies and organizations that advance the

participation of underrepresented students in stem to develop the audit tool over the course of a year and a series of facilitated meetings and workshops. this process will include an in-person workshop meeting at the joint aquatic sciences meeting (jasm), as well as a series of remote meetings both before and after the in-person meeting. jasm2022 is expected to be the largest gathering of aquatic scientists to date and thus an opportunity to engage diverse societies and their leadership in collective planning. the development of the audit tool will be the first step in creating cultural change, by helping cass societies determine where barriers to participation exist. the audit tool and a compilation of current best practices for engaging members of underrepresented groups in aquatic sciences will be disseminated widely on our websites, through the nsf includes network, and conference presentations and publications. the idea audit tool, as well as lessons learned from the development process, will be shared with other societies wanting to broaden participation among their professional members. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Varieties of Crises, Elite Responses, and Executive Approval

Awardee: University of Mississippi

Amount: \$70,176.00

Abstract: this award is funded in whole or in part under the american rescue plan act of 2021 (public law 117-2. this project examines four major types of crises -- economic, security, natural disaster, and public health crises ? and how they influence public support for political leaders in contemporary democracies. this is important to understand because leader approval is a key barometer of policymaker accountability and democratic stability, both of which can be undermined by crises. this project analyzes the interplay of four factors which vary systematically across these different types of crises and how, in turn, these shape public evaluations of political executives: (1) the ability of

citizens to assign responsibility for policy decisions and outcomes; (2) the degree of expert consensus on effective policy response; (3) how much a given crisis in one area generates acute challenges or crises in other areas; and (4) the extent to which an effective response depends on citizens acting collectively. several data sets including (quarterly) measures of executive approval and crises; the tone and salience of leader messaging about the crises; the media's treatment of leader messaging; and (monthly) leader approval for a smaller number of countries for which such data is available; and survey-based experiments in three countries are collected and made publicly available. the award supports education and **\*\*diversity\*\*** by building the research capacity of a student project lab at georgia state university, a minority serving institution, in coordination with pisa at four other universities who will also engage graduate and undergraduate students in this work.

puzzling divergences across countries in public reactions to leader responses to the covid-19 public health crisis have revealed major gaps in our understanding of how crisis events translate into public assessments of leaders. to resolve these puzzles, this project advances a unifying theoretical framework that identifies four major types of crises: economic, security, natural disaster, and public health. it then locates these crises on four key dimensions which should condition public support of top officials: the institutional and political context and other factors that impact attribution of responsibility, degree of expert consensus and incentives for politicians to follow expert recommendations, the likelihood and nature of spill-over to other crisis types, and the degree to which citizen action is required for an effective response. the project collects data to test theoretically-motivated hypotheses using: 1) a macro time-series cross-national data set to study the effects of crisis type on public approval for political executives for 48 countries, 2) a high-frequency time-series data set appropriate to test how approval dynamics reflect leader responses, as well as messaging choices and media effects for 18 countries for which this data is available, and 3) conjoint experiments in france, italy, and mexico, countries with different political and institutional settings, to assess the validity of the links between crisis types and dimensions as well as to validate proposed individual-level mechanisms. this project is supported by the accountable institutions

and behavior program and the sbe build and broaden program. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Belmont Forum Collaborative Research: Residual Risk of Extreme Floods: a challenge for achieving sustainable development goals

Awardee: University of California-Berkeley

Amount: \$70,000.00

Abstract: this award provides support to u.s. researchers participating in a project competitively selected by a 55-country initiative on global change research through the belmont forum. the belmont forum is a consortium of research funding organizations focused on support for transdisciplinary approaches to global environmental change challenges and opportunities. it aims to accelerate delivery of the international research most urgently needed to remove critical barriers to sustainability by aligning and mobilizing international resources. each partner country provides funding for their researchers within a consortium to alleviate the need for funds to cross international borders. this approach facilitates effective leveraging of national resources to support excellent research on topics of global relevance best tackled through a multinational approach, recognizing that global challenges need global solutions. this award provides support for the u.s. researchers to cooperate in consortia that consist of partners from at least three of the participating countries. the teams will establish transdisciplinary networks to develop innovative solutions for sustainable development pathways and seek to assess the positive and negative inter-linkages between the economy, technology, institutions with the environment, climate, bio\*\*diversity\*\*, and human well-being to understand potential pathways to a sustainable world. the project will create an international network of experts and a community of practice to address the residual risk of flooding damage to help inform sustainable development. the exposure of human populations to flooding has increased in the last several decades, but many people are unaware that they reside in flooding risk zones. residual risk of extreme floods (rreflood) project aims to help manage this risk and increase communication with the public by creating a network focused on the interplay among residual risk and its management. the project members will collaboratively design a framework to integrate

residual risk in local planning efforts, create a platform to facilitate advances in basic knowledge and tools to reduce residual flood risk, and identify research needs that will be beneficial to countries worldwide. this project will promote mechanisms to raise capacity for effective climate change-related planning and management and will identify effective ways to communicate the residual flood risk to residents and stakeholders, with the goal to reduce the adverse effects of natural disasters. the international scientific community will be enhanced by the addition of a novel network of experts on residual flood risk; this network will facilitate exchanges and mutual learning to improve methods in global practice. the rreflood project will thus create a new community around global flood risk and engage in pathways to sustainability through global research and community support. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Understanding How Students' Sense of Belonging Develops During Undergraduate Field Experiences: Supports, Barriers, and Implications for Faculty

Awardee: Regents of the University of Michigan - Ann Arbor

Amount: \$68,875.00

Abstract: this project aims to serve the national interest by addressing a critical need in the scholarship of stem teaching and learning. specifically, it is designed to advance understanding about how students' sense of belonging develops in undergraduate learning experiences outside of the traditional classroom. the project will focus on residential undergraduate field courses, a pivotal learning experience in stem disciplines such as ecology, geology, and geography. a sense of belonging plays an important role in students' mental health and well-being, academic achievement and motivation, and institution-level retention. it is also pivotal for the persistence of students from communities that are underrepresented in stem disciplines. the overarching goal of the project is to build the capacity of geosciences and biology faculty to support the development of students' sense of belonging. in this way, it can help to improve the inclusivity of courses that are a critical pathway for thousands of undergraduate students in field-based stem disciplines. this project has the potential for broad reach and impact on student engagement and learning in multiple stem disciplines and is likely to have a positive impact on the inclusivity of undergraduate field education. it may be especially important for students from communities that have been historically excluded from field-based stem disciplines, whose persistence is strongly linked to sense of belonging in the scientific community. the project focuses on advancing understanding about how students' sense of belonging develops in residential field experiences and builds capacity for faculty from geosciences and biology to support the growth of students' sense of belonging. the following objectives will guide the project study: 1) identify factors that contribute to and hinder the development of students' sense of belonging during residential geosciences and biology undergraduate field courses; 2) characterize the design and implementation of geosciences and biology undergraduate field courses, specifically what practices faculty are using and what challenges and needs exist for the development of students' sense of belonging during undergraduate field courses; 3) create an empirically-based framework of how students' sense of belonging develops during residential undergraduate field courses; 4) facilitate a community of practice that uses and contributes to promising practices for the design and assessment of inclusive field courses that support the

development of students' sense of belonging; and 5) articulate a suite of promising practices that have the potential to promote the development of students' sense of belonging during a range of formats of undergraduate field courses and for students from different backgrounds. using innovative and robust mixed methods research approaches, this work will contribute to the wider body of evidence-based, student-centered practices in undergraduate stem education. the work has the potential to provide a deep and impactful contribution to the fields of discipline-based education research (particularly in geosciences and biology), higher education, education and social psychology, and **\*\*diversity\*\***, equity, and inclusion. the nsf iuse: ehr program supports research and development projects to improve the effectiveness of stem education for all students. through the engaged student learning track, the program supports the creation, exploration, and implementation of promising practices and tools. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Research Initiation: Social Engagement & Belonging in Academic Makerspaces

Awardee: University of Texas at Austin

Amount: \$68,205.00

Abstract: academic makerspaces provide students with open access to resources that help them develop their problem solving skills, provide opportunities for collaboration, and encourage experimentation and discovery. however, recent research has shown that many makerspace environments do not readily support diverse populations, create tensions between different student groups, and can sometimes lead to a work environment that feels exclusive and unwelcoming. it is essential that our academic makerspaces are welcoming and that all students feel a sense of belonging and acceptance in these spaces. this project will use the flexible nature of an academic makerspace as the framework to provide students with the opportunity to connect socially in ways that have been shown to increase sense of belonging. this will be accomplished by integrating social engagement activities into a university affiliated makerspace. the engagement activities will be designed to support students' social and emotional development, which is an essential component to creating culturally competent, well-rounded engineers. due to the flexible and informal nature of the makerspace environment, it is an ideal place to build and create social connections between students. makerspaces provide a venue for informal learning and student connection that inspires

attributes associated with the professional formation of engineers: creativity, discovery, lifelong learning, teamwork, and critical thinking. this study will lay the foundation for future research that will inform strategies to create an equitable and inclusive makerspace culture with a focus on better supporting non-dominate students. this project aims to increase student sense of belonging in undergraduate engineering students through the integration of social engagement activities into an academic makerspace. the objectives of this project are to (1) strategically integrate social engagement activities that have been shown to contribute to increased sense of belonging and student persistence into an academic makerspace; (2) research the effects of the social engagement activities on student sense of belonging; and (3) increase engineering education research capacity at western washington university. the outcomes of this work will lead to identification of best practices for improving student sense of belonging in a makerspace environment. this research will investigate the impact of carefully designed social engagement activities on development of student sense of belonging. within the recent context of the covid-19 pandemic, social support and positive sense of belonging have been shown to counter the adverse social emotional effects of the experience. engagement activities will focus on supporting student social and emotional development, providing peer support, and building awareness of the importance of equity, inclusion, and **\*\*diversity\*\*** in engineering. the activities will be designed so that any student can participate regardless of ability level, time availability, or physical location. the research questions that will guide this work are (1) to what extent do students participate in the engagement activities within the makerspace and in which formats, and does this level of engagement vary based on student demographics? and (2) to what extent does participation in the engagement activities lead to an increased sense of belonging? these research questions will be investigated through a communities of practice theoretical framework using a two-year mixed methods research that includes survey development, analysis, student reflections, and focus groups. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Characterizing Inclusive Strategies that Retain Black Students in Computer Science to Graduation and Beyond

Awardee: Morehouse College

Amount: \$66,464.00

Abstract: this iuse project aims to serve the national interest by identifying factors that lead to the lack of **\*\*diversity\*\*** in computing professions. research has shown that the first two years of science, technology, engineering, and mathematics (stem) majors are often where students are lost in the pipeline. this project will identify factors that affect the retention and graduation of under-represented minority students in the computing major. the goals are to identify inclusive strategies for success in computing programs and investigate ways to increase the retention and post-graduation success of black students in computing. of particular interest are strategies that are transferable to different types of institutions and stem fields in general. this project features a collaboration between two historically black colleges/universities and a primarily white institution that will work together to understand the challenges facing each institution and the strengths each institution brings to addressing this problem. through detailed transcript analysis, this research will take an asset-based approach, focusing on the strengths of students succeeding in the major. two cohorts of lower division (freshman and sophomore) black cs students from two historically black colleges/universities (hbcus) and one primarily white institution (pwi) will be studied to measure perceived societal impacts and their understanding of content through conceptual assessment instruments. a cohort of upper division students will be studied to measure the factors that led to their success using surveys, a content assessment, and interviews. using a mixed methods analysis approach, white students will be compared to black students at the research intensive pwi and then the principal investigators will compare black students at the pwi to black students at the two hbcus. the goal is to expand knowledge of inclusive teaching strategies and provide institutional awareness

of factors that can go beyond recruiting urms to focus on retention in the major and student success post-graduation. the nsf iuse: ehr program supports research and development projects to improve the effectiveness of stem education for all students. through its engaged student learning track, the program supports the creation, exploration, and implementation of promising practices and tools. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: ABI Innovation: FuTRES, an Ontology-Based Functional Trait Resource for Paleo- and Neo-biologists

Awardee: Battelle Memorial Institute

Amount: \$65,744.00

Abstract: physical characteristics of animals can help determine which ones survive and flourish, especially in a changing environment. these characteristics, also known as functional traits, include features such as length, height, shape, weight, growth rate, sex, and reproductive state. studying these traits provides insights into how communities of different types of animals come together and how species and communities respond to changes in their environment over time, which is critical for conservation efforts. however, very little information about functional traits is available, and what is available is difficult to combine with other data. how these traits are influenced by environmental changes - such as climate change, pollution, urbanization and human predation - and how they shift over longer timescales are poorly understood, and the need for this information is outstripping the speed with which scientists can collect these data. digitized collections of animals representing life from the past two million years contain a treasure trove of information about these individuals' functional traits, but these data are stored in multiple places and in different formats. researchers may have recorded dates differently, for example, or used a variety of terms to describe a single physical feature. making these data widely available in standardized formats could help scientists

study changes in functional traits through time, linking their observations of traits of modern animals to those from fossil and archaeological records. the functional trait resource for environmental studies (futures) project will gather trait data from digitized records; to engage communities of researchers to make these data available, standardized, and useable; and to develop a more complete workflow for using these data in research. functional trait data have revolutionized ecology and are transforming paleontology, but acquiring them requires extensive labor, not only in measuring traits but in managing and communicating the resulting data. when trait data are lacking, researchers substitute average values, or other characteristics like behavioral or dietary categories. these substitutes - assigned at the species level - obscure intraspecific changes in traits. futures fills the clear need for informatics tools that give researchers access to existing trait data and a place to store new data as they are generated. futures is assembling a varied collection of existing trait data, building a pipeline that converts data to an integrated, semantically enriched form, and developing an application programming interface (api) and web platform to serve the data. one of the key innovations of futures is the use of ontologies, an information science approach that creates computer-readable definitions of traits and describes the interrelationships of traits, organisms, collecting events, and other entities. in this way, futures will make functional trait data searchable through reference to time, space, and vertebrate anatomy. futures will also provide access to trait data via popular data portals (e.g., vertnet) and software such as r, opening the data to scientists in bio\*\*diversity\*\* and other domains. the toolkit will be tested with mammalian use cases that leverage the massive scale of the unlocked data. in sum, newly created access mechanisms and tools will provide novel approaches for analyses of trait variation across space and time, providing researchers in disparate fields discovery capabilities for relevant data that would otherwise have been invisible to them. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Belmont Forum Collaborative Research: AWERRS Arctic Wetlands Ecosystems ? Resilience through Restoration & Stewardship

Awardee: University of Alaska Southeast Juneau Campus

Amount: \$65,378.00

Abstract: this award provides support to u.s. researchers participating in a project competitively selected by a 9-country initiative on global change research through the belmont forum. the belmont forum is a consortium of research funding organizations representing over 55 countries focused on support for transdisciplinary approaches to global environmental change challenges and opportunities. it aims to accelerate delivery of the international research most urgently needed to remove critical barriers to sustainability by aligning and mobilizing international resources. each partner country provides funding for their researchers within a consortium to alleviate the need for funds to cross international borders. this approach facilitates effective leveraging of national resources to support excellent research on topics of global relevance best tackled through a multinational approach, recognizing that global challenges need global solutions. this award provides support for the u.s. researchers to cooperate in consortia that consist of partners from at least three of the participating countries. the research teams will address key areas of arctic resilience understanding and action. this collaboration of academic and non-academic knowledge systems constitutes a transdisciplinary approach that will advance not only understanding of the fundamentals of arctic resilience but also spur action, inform decision-making, and translate into solutions for resilience. the project seeks to address the challenge of building resilience in a rapidly changing arctic by focusing on human activities that impact arctic wetlands ecosystems. the project will support and help communities to strengthen their capacity to engage in wetlands restoration and stewardship. at a local scale, wetlands buffer heavy precipitation and snowmelt and filter and store water. they provide crucial habitat for bio\*\*diversity\*\*, providing nesting and breeding areas for migratory bird species and spawning areas for fish species. as such, they support

traditional livelihoods activities including reindeer husbandry, hunting and fishing, other cultural and recreational activities, and tourism. less widely known is that intact wetlands store a large amount of global carbon. while they make up only about 3% of the earth's land area, wetlands store an estimated 20% of the worlds terrestrial carbon ? the largest regional store of carbon on the planet. identifying and testing approaches for strengthening the engagement of local communities and other actors in the restoration and stewardship of arctic wetlands ecosystems helps increase community resilience though shared engagement - and through the ecosystem service benefits derived from improving wetlands ecosystems' resilience. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: ISS: Collaborative Research: Individual and Collective Behavior of Active Colloids in Microgravity

Awardee: Colorado Mesa University

Amount: \$60,971.00

Abstract: this nsf-casis project involves microgravity experiments on the international space station (iss), complementary terrestrial experiments and theoretical/numerical modeling to improve understanding of active colloid transport. active colloids move by extracting energy from their surroundings and transforming it into mechanical work. these materials have similarities with biological matter, especially for concentrated suspensions where particle-particle interactions yield collective behaviors similar to those found in nature such as swarming flocks of birds, schools of fish and bacterial colonies. although most theoretical models pertain to an isolated particle traveling in the bulk, the weight of active colloids on earth causes them to settle at the bottom of the experimental chamber where they translate parallel to the surface. long term microgravity conditions on the iss offer a unique opportunity to mitigate buoyancy and sedimentation and obtain bulk

measurements that can be compared with theoretical models and elucidate the role of particle-wall interactions, which complicate terrestrial experiments. the results of this project may transform a variety of applications in biomedicine and applications at the food-water-energy nexus including colloidal assembly and bubble/droplet transport. the project is a collaboration between colorado mesa university (cmu) - a primary undergraduate institution with a diverse student body and florida international university (fiu) - a research intensive minority serving institution (msi). it offers a unique opportunity to promote **diversity** through exposure of undergraduate students to timely research and industry collaboration with the implementation partner space tango. the research team will develop a module for fiu's "engineers on wheels" program, which visits local schools, and will collaborate with the eureka science museum and maverick innovation center in colorado. this nsf-casis project will provide a comprehensive understanding of complex physical mechanisms controlling the mobility of individual active colloids and their collective behavior with two distinct goals: (1) optimizing active colloid transport, and (2) understanding effects of microgravity on collective dynamics and non-equilibrium interactions of active matter. the absence of buoyancy in microgravity is expected to resolve a conundrum in terrestrial experiments wherein theoretical models of these systems are derived for isolated particles in the bulk while experimental measurements are almost always made near a wall owing to gravity-induced sedimentation. proximity to a wall and the accompanying particle-wall interactions (hydrodynamic, phoretic, electrostatic etc.) are often invoked as corrections to explain discrepancies between theory and experiment. however, the precise roles of particle-wall interactions cannot be isolated without comparable measurements far from the wall. sustained microgravity conditions will enable measurement of particle mobility in the bulk, providing an experimental reference for theoretical models and insight into competing buoyancy effects and wall-particle interactions. comparison of particle-particle interactions on earth and on the iss will also elucidate effects of microgravity on collective behavior in active matter and dense colloidal systems including 3d phase separation. microgravity experiments will be complemented with terrestrial bulk measurements using optical

tweezers as an external forcing mechanism, which will provide insight into other active colloid transport mechanisms (e.g., catalytic) and the applicability of such external forcing for future fundamental studies. the collaboration between fiu and cmu and the partnership with space tango offers a unique opportunity to engage students. undergraduate students will participate through capstone projects at fiu, while cmu students will travel to fiu and gain exposure to a research intensive institution. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Expanding The Capacity Of The Center for Infrastructure Transformation and Education Through Integrating Diversity, Equity, and Inclusion into Infrastructure Education

Awardee: Lafayette College

Amount: \$60,899.00

Abstract: this project aims to serve the national interest by expanding the capacity of the center for infrastructure transformation and education (cit-e) to support civil, construction, and environmental engineering faculty members in their efforts to integrate **\*\*diversity\*\***, equity, and inclusion (dei) into infrastructure education. the causes of inequitable infrastructure are many; however, given its leading role in infrastructure-related education and research, the civil and environmental engineering (cee) faculty has an obligation to recognize and address the need for systemic change. historically, cee faculty members have not received formal training on dei issues. while such training is becoming more common, a gap remains. this level 1 capacity building project will support cit-e, an existing and thriving community of practice (cop), through providing the foundation for future work in developing a multi-institutional effort to transform the cee education community into a community that can sustain growth in dei integration. the collaborative research project is a joint effort by the university of wisconsin, platteville, lafayette college, colorado state university, and virginia

polytechnic institute and state university. with the increased capacity generated by this expanded network and a shared vision, the cit-e cop work will be transformative. leveraging the cit-e and the cop, the project frames the work through the lens of two continua: race neutral/race conscious and inclusion infrastructure/exclusion infrastructure. this project will develop i) cit-e communal understanding of how dei and infrastructure are related; ii) what the interaction among members reveals about dei; iii) how members of the cop can educate one another by addressing dei issues in education, research, and professional practice; and iv) how the cop can inspire real and lasting change. specifically, this project will increase the capacity of cit-e through the following project objectives: i) gather evidence by compiling a list of non-normative examples of successful institutional efforts that positively impact dei; ii) assess cit-e resources and needs via asset mapping; iii) evaluate community of practice as an appropriate change theory; iv) recruit additional stakeholders and organizations to cit-e based on the gaps identified in previous project objectives; v) identify, cluster, and prioritize ways of integrating dei into cee education using group concept mapping (gcm); and vi) provide the foundation for developing a multi-institutional effort to transform the cee education community into a community that can sustain growth in dei integration. the research team will ensure that key stakeholders, including experts in change theory, dei strategies, and curriculum development are invited to provide external peer review of the project. the research team will facilitate working sessions to address larger tasks such as gcm and asset mapping. through a collaboration with the institute for research in the social sciences (iriss), the project will i) build the capacity of the geographically-dispersed research team by accelerating the team's integration to operate as a highly-functioning team and ii) explore how team science might add value to efforts to expand the work.

the nsf iuse: ehr program supports research and development projects to improve the effectiveness of stem education for all students. through the institutional and community transformation track, the program supports efforts to transform and improve stem education across institutions of higher education and disciplinary communities. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the

Title: Annual REU Site Intersection of Linguistics, Language and Culture Conference

Awardee: MOLLOY UNIVERSITY

Amount: \$58,364.00

Abstract: this award is funded in whole or in part under the american rescue plan act of 2021 (public law 117-2). the nsf reu ilc annual 2021 and 2022 conferences will coincide with and complement the 2nd cycle of the nsf research experience for undergraduates site 'intersection of linguistics, language and culture' (ilc) housed by molloy college, long island and cuny brooklyn college, both in new york. the conferences aim at increasing **\*\*diversity\*\*** among emerging researchers and among the projects undertaken by future researchers and professionals in linguistics and speech-language-communication sciences. they will involve five components: (i) undergraduate projects by members of cultural, ethnic and linguistic groups underrepresented in higher education,

with a focus on novel findings in their language/language varieties, and on stem-based innovative methodologies and explanations of broader impacts; (ii) participation of high school students so that they discover linguistics and the research areas and professions associated with linguistics, before they enter college; (iii) empowerment of undergraduate and high school students, especially members of groups underrepresented in higher education, to become emergent scholars and valued members of higher education institutions in the process of the organization of the conference; (iv) dissemination of the conference oral and poster presentations during and beyond the conference through two complementary platforms: open-access publications of proceedings and video presentations; (v) recognition and valuing of college and high school participation and work through the competitive awarding of travel expenses and prizes. the proposed conferences will disseminate novel findings that reflect the u.s. and world cultural, ethnic and linguistic **\*\*diversity\*\*** and that are needed to advance the field. the proposed conferences will have three sets of broader impacts including (i) the clinical, educational and technological implications of the findings that emerge from the projects conducted by the nsf reu illc site fellows and the poster presenters, (ii) the increase of **\*\*diversity\*\*** of the workforce among researchers and professionals in speech-language-hearing-communication sciences, (iii) the increase of knowledge in the general population of the significance of linguistics, the fact that it is a stem-based discipline and that various professional sectors exhibiting rapid growth value both linguistic training and the ethnic, cultural and linguistic heritage of minority students from groups underrepresented in higher education this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: RAPID: REU Site: A Virtual Research Experience in Macromolecular Structure and Function

Awardee: University of Illinois at Chicago

Amount: \$57,970.00

Abstract: the covid pandemic has caused closures of reu sites in summer 2020. the situation continues this summer 2021 with some reu programs already posting cancellations. this rapid proposal will mitigate the inadequate number of available opportunities for students. the university of illinois at chicago (uic), located in chicago, illinois, will support the training of seven students for eight weeks during the summer of 2021. research will be conducted online with faculty located in chicago, evanston (il), and dallas (tx). the students, who are from groups under-represented in science or from schools with limited research opportunities, will learn how research is conducted, and many will present the results of their work at scientific conferences. this program provides vital training, mentoring, and professional skills development to enable and encourage talented students to continue in degrees and careers in science, which is vital for the future of us science and the economy. students will participate in full-time mentored research projects using state-of-the-art computer-based methods to advance our understanding of the structure and function of dna, proteins and other macromolecules. assessment of the program will be done through the online salg urssa tool. students will be tracked after the program in order to determine their career paths. the scientific theme of the program is macromolecular structure and function. faculty mentors come from uic departments of biology, physics, and bioengineering, the university of chicago biological sciences collegiate division, the university of texas southwestern medical center green center for systems biology, and the northwestern university molecular biosciences department. the computer-based projects include elucidating protein functional sites, conformational changes involved in aggregation, cellular targeting signals, and mechanisms of nutrient uptake. program components include professional skills training in ethical issues, responsible conduct of research, **\*\*diversity\*\*** and inclusion, science careers, and oral and written scientific communication. participants will present their accomplishments at a research symposium. more information is available by visiting [/bios.uic.edu/profiles/jeffery-constance-j/](https://bios.uic.edu/profiles/jeffery-constance-j/), or by contacting the pi (prof. jeffery, [cjeffery@uic.edu](mailto:cjeffery@uic.edu)). this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review

criteria.

Title: Collaborative Research: BPC-AE: STARS: Catalyzing Action-Oriented Academic Communities for Broadening Participation in Computing

Awardee: Florida State University

Amount: \$57,000.00

Abstract: it is critical to address the longstanding issue of underrepresentation of women, black, and hispanic students in computing degree programs to provide an equitable foundation for all to participate in our society and the global economy as controllers and creators of technology, and to advance the preparation of a diverse, innovative, and competitive tech workforce. building on the prior success of the stars computing corps alliance for broadening participation in computing, the goal of the stars catalyst project is to: 1) increase the number of women, black, and hispanic students that persist in computing degree programs, and 2) advance the careers of students and faculty from groups that have been historically underrepresented in computing. through research and evaluation around stars catalyst activities, this project will advance knowledge about practices designed to increase persistence and support career advancement in computing for college computing students and faculty, particularly for those from underrepresented and intersectional groups in computing. the stars catalyst alliance is a collaborative effort across temple university, north carolina state, kent state, florida state university, morgan state, and university of north carolina charlotte. the stars computing corps alliance for broadening participation in computing (bpc) engages computing faculty and students at colleges, universities, and community colleges in a community of practice with a shared commitment to take action to advance **diversity**, equity, and inclusion in computing. stars computing corps conferences, communities, and networks create significant institutional and human resources that can expand bpc research to a larger audience of researchers, educators, administrators, cs departments, and k-20 students, and can dramatically

increase the number of people taking action in bpc efforts. prior results show that the stars computing corps alliance increases intentions to persist in computing among stars students and faculty, with enhanced outcomes for black students and faculty. this project will significantly extend the stars alliance to expand upon those impacts, by 1) including new partners that expand the reach of stars and that emphasize participation of black and hispanic students and faculty, particularly from emerging hispanic serving institutions and community colleges, 2) creating new program elements that test new and propagate evidence-based bpc practices within computing departments, and 3) leveraging partnerships to support identity-focused affinity groups, and 4) developing stars alumni groups employed in industry positions to promote transition to and retention within the tech workforce. extensions to the stars leadership corps program, stars launch program, and the stars celebration conference will serve to develop and propagate evidence-based approaches aimed at improving the teaching and learning of computing for black and hispanic students and build evidence of their effectiveness, and the respect research conference will continue to advance peer-reviewed bpc scholarship. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Linking predator functional diversity to prey dynamics through the functional response

Awardee: Florida Atlantic University

Amount: \$56,741.00

Abstract: human activities such as habitat modification, harvesting and species introductions are rapidly changing the type and number of predators in aquatic and terrestrial ecosystems. these changes in predator communities can have significant ecological and socio-economic impacts. however, our ability to predict and manage the effect of predator loss or introduction on prey populations on ecosystems remains limited. this study will integrate experimental and mathematical approaches to improve existing tools for predicting the consequences of predator loss or introduction in aquatic ecosystems. the investigators will conduct a series of observations and experiments in rock pools in streams to document the responses of prey to changes to multiple predator populations. the responses include patterns of prey mortality, and alterations in prey behavior or morphology. the data generated from this phase of the study will be used to test the ability of existing and improved models to predict the long- term consequences of predators on prey populations and overall ecosystem function. collectively, the results of this research will significantly advance our ability to predict the consequences of predator loss or invasion. the project will also integrate education with outreach activities in two ways: 1) the investigators will partner with high school teachers to create teaching modules and field labs focusing on predator-prey interactions. 2)

the investigators will participate as mentors in a faculty-mentoring network (nsf-quantitative undergraduate biology education and synthesis project). this network provides support to k-12 teachers and college faculty around the country seeking to implement more rigorous quantitative components in their courses. additionally, the study will provide research training for post-doctoral, graduate and undergraduate students. this project will support an early career investigator, and two investigators at primarily undergraduate institutions. this research will advance our ability to predict how predator loss or introduction affect prey populations and influence other ecosystem functions by focusing on the overall effect of multiple predators. the study will combine theoretical, statistical and empirical approaches and will include the following activities: 1) field surveys to measure density, size and species composition of predator and prey communities in rocky pools. 2) experiments to measure prey survival, fecundity and growth as functions of prey density and size, predator identity and food resources. 3) use of the data and patterns observed in the field and experiments to develop new models for predicting prevalence and magnitude of emergent multiple predator effects. 4) experimentally test predictions of the existing and improved models to quantify the importance of predator species and functional **\*\*diversity\*\*** on prey population dynamics in rock pool food webs.

Title: Collaborative Research: Hominoid origins in a unique paleocommunity

Awardee: Oregon State University

Amount: \$54,580.00

Abstract: this project advances knowledge about a crucial time in primate evolution when the ancestors of apes and humans are thought to have first diverged from other primate lines. a team of experts in paleoanthropology, paleontology and geology are conducting excavations and analyzing fossils and paleoenvironmental data from a fossil-bearing site in order to better understand the environmental context for primate adaptations and ecological **\*\*diversity\*\***. the project offers invaluable research and training opportunities to scientists and students, including individuals from

groups underrepresented in stem, and provides opportunities for science outreach about human origins and climate change with local communities and the general public. an extraordinary new fossil primate site provides an opportunity to obtain new data related to the origins of the hominoids during the oligocene. the primary objective of the project is to characterize the species **\*\*diversity\*\*** and paleoenvironmental context for the site. the central hypothesis is that the earliest stem hominoids arose within unique ecological communities that were very unlike those of the later miocene hominoid radiations. the team of paleoanthropologists, geologists, and paleontologists carry out this work through additional fieldwork and analysis of the hundreds of fossils and geological samples already obtained. the goals are three-fold: (1) characterize the paleobiological disparity between hominoids and cercopithecoids in the mid-oligocene by analyzing functional disparity; (2) build out a robust geologic framework that integrates current and future fossil localities into a well constrained chronology; and (3) characterize the mammalian community **\*\*diversity\*\*** by contextualizing its taxonomic, functional, and phylogenetic composition. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: US GEOTRACES GP17-OCE: Mapping nitrous oxide sources and sinks through isotopic measurements in the Pacific Ocean

Awardee: University of South Carolina at Columbia

Amount: \$54,049.00

Abstract: nitrous oxide is a powerful greenhouse gas that is produced by microbial activity in soils and the ocean. the pacific ocean is an important component of oceanic nitrous oxide production and emission to the atmosphere due to its large area and pockets of low oxygen in the eastern tropical pacific. the largest amounts of nitrous oxide observed in the global ocean occur in these pockets of low oxygen. these regions appear to impact nitrous oxide distributions throughout the pacific ocean,

but the sources of nitrous oxide in these regions may be quite different. this work will provide a better understanding of both the natural distribution of nitrous oxide in the global ocean, as well as the mechanisms and controls on its production for future emission projections. this will be accomplished by collecting nitrous oxide isotopic measurements at different water depths from the central pacific, where relatively little work has focused. measurements of nitrous oxide isotopic composition is a powerful analytical tool that will help to answer these important questions about this powerful greenhouse gas. the stanford component of this project will be carried out primarily by a phd student, who will be trained in a variety of laboratory techniques, data analysis, and computer modeling. we will also use support from this project to increase **\*\*diversity\*\*** in the geosciences by providing first-time research experiences to underrepresented minority students through stanford's surge (summer undergraduate research in geoscience and engineering) program. one of the project's lead investigators, bourbonnais, will also give a series of introductory chemical oceanography lectures at benedict college, a private historically black, liberal arts college in columbia, sc and support two undergraduate students from benedict college through summer internships at the university of south carolina. this project will address three main questions related to n<sub>2</sub>o cycling in the pacific ocean: (1) what features of n<sub>2</sub>o distribution in the central pacific ocean are driven primarily through mixing and circulation vs. biological processes; (2) which biogeochemical processes control the distribution of biologically produced n<sub>2</sub>o in the central pacific ocean; and (3) how does the production (amount, mechanism, yield) of n<sub>2</sub>o relate to the availability of oxygen in situ? this collaborative project will be carried under the geotraces program, an international effort to understand the distribution of elements in the global ocean. with the synthesis of the geotraces gp17 and gp15 sections, we will have an opportunity to examine the distributions of n<sub>2</sub>o and its isotopes (an indicator of production mechanisms) relative to oxygen, trace elements, and water mass tracers. data from this project will be made available to the public through the biological and chemical oceanography-data management office ([www.bco-dmo.org](http://www.bco-dmo.org)). the data will also be compiled in geotraces data products that will be freely available. this award reflects nsf's statutory

mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: NSF-sponsored workshop: The cross-disciplinary study of post-transcriptional and post-translational modifications: Finding the commonalities of interests, approaches, and future di

Awardee: University of Pennsylvania

Amount: \$52,707.00

Abstract: every organism on earth relies on its dna content (i.e., genome) to direct its life, growth, and development. however, the genome is not the destiny of the organism. for example, caterpillars and butterflies have exactly the same genome, but distinct forms. the difference can be largely attributed to the other important biomolecules that are encoded by the genome. these biomolecules are rna and proteins, which can be modified in hundreds of different ways after their synthesis. recognition of the **\*\*diversity\*\*** and complexity of modifications of rna and proteins has changed how we think about their different functions of these molecules in fundamental ways in both large and small organisms, ranging from microbes to plants and humans. understanding how rna and proteins are modified, and their biological implications is very important in many areas of basic and applied biological and medical research. improving our understanding will require building community resources, technical breakthroughs, and cross-disciplinary research efforts to achieve cross-cutting advances in rna and protein biology. this project will support a virtual national workshop that will bring together 100-150 diverse participants that are actively involved in both the meeting and discussion sessions. in addition, all research talks, and discussion sessions will be open for anyone interested to watch through zoom. the participants are from many different disciplines and areas, including plant, animal, and human biology, and cover research areas such as chemistry, engineering, computer science, artificial intelligence, and systems and synthetic biology. keynote talks from leaders, small-group and interactive sessions will facilitate and stimulate researchers to

address the following key topics: 1) successes and failures in rna and protein modification research in a variety of research organisms; 2) experimental systems as well as research approaches that leverage all rna and protein-related scientific disciplines; 3) possible "rules of life" to guide baseline and comparative questions across the different realms of organisms; 4) advantages and disadvantages of currently available tools, consortia, and databases; 5) training needs for researchers capable of contributing to future advancement in rna and protein biology; and 6) short- and medium-term research and knowledge goals, noting potential strategies to reach these goals.

in the framework of our current understanding of genetic information flow, post-transcriptional modifications (prms) of rna molecules and post-translational modifications (ptms) of proteins are extremely important cellular regulatory moieties. yet significant gaps remain in the integrated understanding of these two regulatory moieties and their effects on overall cellular metabolism in different biological organisms. fragmented research efforts in different systems (e.g., microbe, plant, animal, and human) and using different approaches and standards, has prevented integrative analyses of different datasets and identification of common principles of prms and ptms. this workshop aims to fill these gaps and advance research from descriptive and specific mechanistic focus towards integration, general theory, modeling and prediction, and global understanding. moreover, this workshop will promote studying the functions and mechanisms of the key regulatory modifications, of their roles in cellular signaling and metabolism, as well as their impact on organisms. the workshop will provide significant opportunities for cross-disciplinary interactions to advance the field of rna and protein biology by identifying: 1) core questions driving/prm and ptm studies; 2) conceptual and theoretical foundations that provide a useful lens for hypothesis testing; 3) big ideas to drive advances in these areas and increased understanding of the rules of life; and 4) a path forward for collaborative research and synthetic analyses that will further integrate the two closely-related areas of research through multidisciplinary approaches. early-career post-doctoral scientists and graduate students will participate in the workshop organization and serve as virtual discussion leaders, providing them the opportunity to network with many of the

leaders in these cutting-edge fields. the workshop aims to increase broad participation of underrepresented groups in rna and protein modification research, and serves as a model for integration of inclusive and interactive online conference opportunities allowing participation from broader audiences. collectively, this workshop will identify critical gaps in resources and understanding of prms and ptms across disciplines, and importantly draft a path forward for community-wide collaborative research to advance these important areas of research that affect our understanding of human, plant, animal, and ecosystem biology. funding for this workshop was provided by the physiological and structural systems cluster, plant genome research program, and genetic mechanisms cluster in the bio directorate and the cellular and biochemical engineering program in the eng directorate. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Expanding Participation for Women and Minorities in the 2022 Neurobiology of Cognition  
Gordon Research Seminar & Conference

Awardee: Gordon Research Conferences

Amount: \$50,250.00

Abstract: the field of cognitive neuroscience has expanded by leaps and bounds over the past 20 years - the number of yearly publications has increased 20-fold over these two decades. bringing the cognitive neuroscience community together for focused and in-depth discussion of cutting edge research every two years is incredibly valuable (the 2020 gordon conference was not held because of the pandemic). meanwhile there has also been an explosion of information in molecular, cellular, circuit and systems neuroscience but little of that information has made significant inroads into our understanding of cognitive function. this gordon research conference on the neurobiology of cognition should help bridge the gap, at the very least by identifying the avenues for connection that

have the most potential for near-term traction and by linking scientist from disparate fields. the gordon conference (grs and grc) will take place in july, 2022. the emphasis of the workshop is to facilitate in-depth discussion between scientists working in divergent fields whose integration is essential to understanding the neurobiology of cognition. nsf support will enable graduate students and postdoctoral trainees and early investigators to participate in this high-profile workshop and will allow early stage investigators (non-tenured) to attend as speakers and full participants. trainee fellowships to cover travel and registration expenses will be preferentially given to women and under-represented minorities in order to enhance \*\*diversity\*\* in the field of cognitive neuroscience.

this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: 2022 Gordon Research Conference on Multifunctional Materials & Structures: Imparting Intelligence in and through Self-Learning Materials & Structures; Ventura, CA; 23-28 Jan 2022

Awardee: Gordon Research Conferences

Amount: \$50,000.00

Abstract: this award will provide financial support to the 2022 gordon research conference on multifunctional materials and structures: imparting intelligence in and through self-learning materials and structures to be held in ventura, california, 23-28 january 2022. this conference seeks to address fundamental scientific issues associated with hierarchical multifunctional material systems from the molecular scale to the structural scale, with principal considerations to intelligence and self-learning. the potential societal benefits and impact of multifunctionality are materials sustainability and energy resource management through material sustainability, recycling, and upcycling; safer systems through adaptive and self-aware capabilities, and improved energy efficiency through mass and/or volume reductions, energy recapture, and ambient harvesting. the conference will seek a broad balance in the speakers, discussion leaders, and attendees including

young and established scientists and engineers, national and international representation from academic, industry, and government institutions/groups, and gender and racial \*\*diversity\*\*. funding through this award would increase the number of graduate students and postdoc participants to prepare the next generation of scientific leaders in this field. in the ongoing series of biennial conferences on multifunctional materials and structures, the focus of this conference is on intelligence and self-learning. researchers will address key scientific issues associated with envisioning, designing, and creating synthetic multifunctional materials and structures with intelligence and self-learning. they will identify gaps and present potential solutions on the integration of these novel functionalities into engineering structures, e.g., how to optimize the disparate roles of interfaces and the design and fabrication approaches. the conference is being organized by leading researchers in this emerging field with deep ties to the worldwide community of scientists and engineers engaged in multifunctional research. the conference outcomes are expected to include novel concepts and mechanisms for achieving intelligence and self-learning, as well as new collaborations and ways of collaborating across disciplines. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Mathematics Leaders Exploring Racial Equity

Awardee: University of Texas at Austin

Amount: \$49,999.00

Abstract: this project aims to serve the national interest by increasing the number of and \*\*diversity\*\* of successful mathematics and stem students. students' experiences in higher education mathematics courses take place in departments. policies and practices relating to student and faculty experiences, admissions criteria and other aspects of departmental have too often contributed to longstanding inequities in representation and outcomes for minoritized students. in

the summer of 2020, amidst the larger national discussion on racial equity, a grassroots workshop brought together over 100 leaders in the mathematics community to understand these disparate racial impacts, brainstorm, and explore opportunities for positive change. participants built a shared understanding and commitment to promote greater racial equity for students and faculty in mathematics departments across the nation. this project looks to expand upon that initial work with a goal of encouraging further discussions and fostering wider transformation in the mathematical sciences community. department chairs, undergraduate and graduate directors, and national math organization leaders will gather regularly in facilitated groups to work through shared readings and analyze departmental policies and practices. each group will engage in conversations relevant to their experiences and institutions with a goal of identifying strategies to more equitably serve their students. some areas of focus for working groups will include mentoring and advising, graduate admissions, and both student-facing and faculty-facing policies. participants will be asked to select an "avenue of change", which is an explicit goal to bring about change in their department or at their institution, and will be held accountable by their peers to carry out this task. in addition to broader dissemination of workshop outcomes, each cohort of participants will share their activities through social media, publications, sessions at national meetings or other means chosen to maximize reach and potential replication. the nsf iuse: ehr program supports research and development projects to improve the effectiveness of stem education for all students. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Transforming Secondary Mathematics Teacher Preparation: A Conference to Focus on Recruitment and Equity

Awardee: University of Nebraska-Lincoln

Amount: \$49,967.00

Abstract: this project aims to serve the national interest by convening a conference focused on increasing the number of higher education institutions that are committed to improving secondary mathematics teacher recruitment and preparation programs, ultimately improving access to high-quality mathematics instructions for 6-12th grade students. the association of mathematics teacher educator?s (amte), get the facts out (gfo) taskforce, and the mathematics teacher education partnership (mte-p), will use this conference as a vehicle to address issues related to recruiting diverse mathematics teacher candidates, exploring transformational efforts relevant to teaching, and examining the role of equity in secondary mathematics teacher recruitment and preparation. new and existing partners will share tools and strategies for solving common challenges and develop ideas for local program transformation efforts. broadening participation in who becomes mathematics teachers is vital; therefore, the project will approach recruitment and program transformation efforts from an equity perspective. at the 2022 mte-p & gfo conference, participants will engage in focused discussions about the significant work of transforming preparation programs to more closely align with the amte?s standards for preparing teachers of mathematics. the conference will be offered in a hybrid format, with participants invited to fully engage either in-person or online. the in-person portion will be held in the same location as the 2022 amte annual conference, one day prior to the amte conference. an evaluation effort will examine (1) the ways in which the conference has expanded the network of partners who focus on secondary mathematics teacher preparation beyond the gfo and mte-p communities, and (2) the degree to which the sessions address equity, **\*\*diversity\*\***, and inclusivity; recruitment strategies; as well as supports for and dimensions of program transformation. information and materials from the mte-p & gfo conference themes and sessions will be disseminated through the amte newsletter and the teaching mathematics teachers podcast. by utilizing ideas of improvement science to support institutional transformation, participants will impact stem educational experiences across k?12 and post-secondary contexts. the nsf iuse: ehr program support research and development projects to improve the effectiveness of stem education for all students. through the engaged student learning

track, the program supports the creation, exploration, and implementation of promising practices and tools. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Cultivating Networks and Innovative Scholarship in Law and Courts, June 2022

Awardee: Wesleyan University

Amount: \$49,961.00

Abstract: in spite of efforts by both professional associations and other groups concerned about the **\*\*diversity\*\*** of the subfield, women and minorities are underrepresented among the scholars who study law and courts. we know that women scholars within the law and courts field, as compared to their male counterparts, face barriers to tenure and promotion due to disparities in resources for research, heavier teaching loads and service expectations, and a lack of parity in placement of law and courts-focused articles in top disciplinary and subfield journals. the effects of these barriers are amplified for those women scholars who are black, indigenous, or from another minority group. this project?a workshop and mentoring community?will serve as one targeted effort to improve representation in the law and courts field. in addition to serving as a space for junior women and nonbinary scholars to gather and receive feedback on their research, the workshop aims to facilitate connections between junior scholars and senior mentors in the field. further, this workshop will invite undergraduate and graduate researchers (those pre-ph.d.) to take part in the professional development sessions. the workshop thus serves a three-fold purpose: it aids in rectifying the ?leaky pipeline? problem for women and non-binary people, assists law and courts scholars in gaining acceptance in the top journals, and facilitates collaborative projects by bringing detached communities together. this workshop will provide a novel forum for cutting edge research on law and courts by junior women scholars to be shared with and reviewed by leading scholars in the field, thus advancing knowledge across a variety of topics within the subfield. this project grows out of a

successful pilot effort conducted over the past year where the researchers: (1) identified members of the community of junior women in law and courts through a widely distributed online survey, (2) developed a series of online peer-to-peer writing groups, and (3) engaged in outreach efforts to decrease the invisibility of research by members of the writing groups and other junior women scholars. the in-person workshop will continue these efforts by bringing together a community of junior women scholars and will augment the pilot efforts by engaging a group of leading women scholars in the subfield for professional development and networking. the workshop will be held in june 2022. participants will be selected through a multi-stage, competitive process which will evaluate the suitability of their projects for the workshop and will also take into account the global **\*\*diversity\*\*** goals of the workshop cohort. at the one-and-a-half-day workshop, scholars will receive feedback on their work from peers and senior scholars and will also participate in professional development and networking panels. workshop participants' progress will be tracked and promoted through the project's outreach channels. it is thus the aim of the proposed workshop and ongoing peer and senior mentoring to assist junior scholars in producing and publishing high-quality research in order to achieve professional success, both at their institutions and in the discipline. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Conference: Math for All

Awardee: Tulane University

Amount: \$49,951.00

Abstract: this three-year award provides support for the annual conference "math for all" in new orleans. the first of the three events will be held on february 4-6, 2022. the overall goal of this conference is to increase **\*\*diversity\*\*** in mathematics and expose mathematicians in the greater new orleans area to research and novel teaching practices as well as provide the opportunity for

networking and developing mentor-mentee relationships. the conference strives to make mathematics more accessible to underrepresented groups, ultimately increasing **\*\*diversity\*\*** in the field. the conference will have participants representing historically black colleges and universities (hbcus) and smaller universities in the new orleans area. one of the goals is to expose the participants to a broad mathematical research community. this aspect of the conference aims to help students transition to research-focused environments, which will increase retention of underrepresented groups in the mathematical fields. the conference will also stimulate discussions among faculty on inclusive pedagogy aimed at advancing students from underrepresented groups. the organizing committee is dedicated to amplifying the voices of underrepresented minorities in mathematics by highlighting the importance of representation, connections, and individual actions towards changing systemic forms of oppression in mathematics. the conference will include four broadly accessible plenary talks, six contributed research sessions, a diverse career panel, two workshops and a poster session. through these avenues, the conference is designed to engage undergraduate and graduate students into a community of mathematics and prepare them for future careers in the field. the plenary speakers and panelists come from around the united states, representing multiple ethnic and mathematical backgrounds, giving students visible role models in industry and academia with whom they can identify. participants will have the opportunity to present research and attend professional development workshops in a welcoming and inclusive environment. the conference will also support a few satellite events. at each of the satellite institutions, the organizers will set up a space for attendees to gather, watch and discuss the plenary talks. the pis will provide the foundation of the math for all conference to the satellite institutions but also allow them to plan their own activities. these satellite conferences will help engage a broader community and amplify the impact of the conference by sharing the resources of the math for all conference, in the hopes of reaching mathematicians who would otherwise not be able to attend the in-person conference. the conference website is: <http://www.math.tulane.edu/mathforallnola> this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation

using the foundation's intellectual merit and broader impacts review criteria.

Title: International Scientific Community Workshop Series on the Access and Benefit Sharing of Digital Sequence Information

Awardee: American Institute of Biological Sciences

Amount: \$49,932.00

Abstract: sequences of biological macromolecules, such as dna, rna, and proteins (collectively ?digital sequence information? or dsi) have become increasingly important to advancing scientific research and discovery worldwide. information of this kind helps scientists understand how genes affect organisms? shape, physiology, behavior, and function. in turn, this knowledge provides the raw material for innovations that will advance human health, food security, and the preservation of bio\*\*diversity\*\* as the climate changes rapidly. the free and unfettered exchange of non-commercial dsi enables the global community of researchers, educators, bio\*\*diversity\*\* collections managers, students, and innovators, including those in the united states, to work fluidly with each other to enable scientific progress. such free flow of information is not guaranteed. discussions have been taking place under the auspices of the united nations convention on biological \*\*diversity\*\* (cbd) and other multilateral bodies to apply a principle known as access and benefit sharing (abs), which was initially developed for physical biological specimens, such as a plant or an insect, to dsi as well. for the most part, the scientists whose research projects depend on openly sharing dsi do not have a seat at the table at which decisions about dsi are being made. this could result in limiting access to information that is currently freely available; indeed, many scientists are unaware that the conversations are even taking place. it is important, then, to ensure that scientists and scientific societies in the united states and elsewhere become more fully engaged in these deliberations, in part by highlighting the importance of transnational collaborations that depend on the exchange of dsi, and making recommendations for how related benefits can be shared. this project will engage

scientific societies, most of which have international memberships, to co-host a workshop series that will educate the community on the issues, perspectives, and requirements that are associated with discussions about dsi/abs in the context of the cbd. the workshops are slated to begin in late summer or early fall of 2021, before the major cbd bio\*\*diversity\*\* negotiations to be held in kunming, china (tentatively in october 2021), and will extend into 2022. activities will include talks from high profile us and international scientists and facilitated discussions tailored to the scientific societies? concerns, which will help to build capacity within societies to accelerate compliant and outstanding bio\*\*diversity\*\* science across geopolitical borders and to develop recommendations that may be helpful to parties to the cbd. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: RAPID: Quantifying Wetland Root Structure, Strength, and Uprooting due to Hurricane Ida

Awardee: Louisiana State University

Amount: \$49,770.00

Abstract: coastal wetlands are valuable ecosystems. they improve water quality, provide wildlife habitat and bio\*\*diversity\*\*, store organic carbon, and protect coastal communities from storms by dampening waves and reducing storm surge heights. yet, severe storms are one of the most common natural drivers of coastal wetland loss. for coastal louisiana, the combined impacts of hurricanes katrina and rita (2005) and then hurricanes gustav and ike (2008) converted nearly the area of new york city into open water. as a result, predicting wetland loss due to hurricanes is an important goal because of the significant consequences with respect to coastal populations. this rapid award will allow timely field testing and core sampling to quantify wetland root strength and structure in the barataria basin of coastal louisiana, which experienced extreme land loss from hurricane ida. this information will help inform the scientific community and public on how the

wetlands are eroded, what controls erosional resistance, why some hurricanes are more damaging than others, and what potential is for long-term recovery. hurricane ida made landfall on the southeastern louisiana coast, bringing storm surge and waves of approximately 4.5 m above the normal water level that caused immense damage to the natural and built environment, specifically undermining the wetland root systems and removing much of the marsh platform. current knowledge of the ability of the wetland platform to withstand hurricane-induced uprooting is limited, and the roles of wetland root structure, biomass volume, and strength need further research. the objective of this rapid research is to collect perishable data of wetland uprooting, including (i) quantifying the micro-scale live biomass, necromass, root structure, pore structure, and sediment density using x-ray computed tomography (xct) scans; (ii) measuring the macro-scale field strength of root systems using cone penetrometer tests (cpts); and (iii) assessing the resilience of wetland vegetation and root systems to recover from a disturbance. this award will develop new knowledge concerning how the wetland platform withstands storm surge and waves, how these systems could evolve over space and time (particularly in the face of sea level rise, restoration activities, and recovery after an extreme event), and how these changes could alter their ability to protect the coastline from further damage. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: The Geoscience Behind Critical Infrastructure Careers; Unlocking the Intrinsic Value of Diverse Communities - a GEO-STEM Learning Ecosystem in Practice

Awardee: LIMITLESS VISTAS, INC

Amount: \$49,710.00

Abstract: there is a well-documented lack of **diversity** in the geoscience classroom, faculty and geoscience professional ranks and environmental workforce. this workshop introduces a diverse population of high school and undergraduate participants to solution based geoscience and potential career pathways. the workshop will help increase the **diversity** in the educational and career pipeline of future geoscience professionals and show participants ways to become active in addressing the impact of public facilities on their communities. working with practicing geoscientists and educators, participants will develop and present on cutting edge environmental infrastructure (water, power, sewer, solid waste, etc.) issues, technologies and careers which affect their daily lives. they will learn the skill sets necessary to become more active participants and problem solvers who are focused on using geoscience to address the impact of public facilities on their communities. this workshop has the potential to increase participants' awareness of environmental infrastructure and the connection to community impacts and stem-related careers. the proposed workshop squarely addresses agu's **diversity** and inclusion strategic plan including to 1) promote and expand collaborative activities... with local community-relevant scientific endeavors, particularly in support of under-served and disadvantaged communities and 2) increase the visibility of education and career paths (in earth science) among diverse audiences and encourage participation in the geosciences. program participants will develop creative content for presentation at the 2020 agu virtual fall meeting - including virtual tours, videos, and interactive communication pieces to demonstrate how new orleans', san francisco's and los angeles' unique geology and seaport locations impact the critical infrastructure of those cities and respective communities. this award reflects nsf's statutory mission and has been deemed worthy of support

through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Awardee: LIMITLESS VISTAS, INC

Amount: \$49,710.00

Abstract: there is a well-documented lack of **\*\*diversity\*\*** in the geoscience classroom, faculty and geoscience professional ranks and environmental workforce. this workshop introduces a diverse population of high school and undergraduate participants to solution based geoscience and potential career pathways. the workshop will help increase the **\*\*diversity\*\*** in the educational and career pipeline of future geoscience professionals and show participants ways to become active in addressing the impact of public facilities on their communities. working with practicing geoscientists and educators, participants will develop and present on cutting edge environmental infrastructure (water, power, sewer, solid waste, etc.) issues, technologies and careers which affect their daily lives. they will learn the skill sets necessary to become more active participants and problem solvers who are focused on using geoscience to address the impact of public facilities on their communities. this workshop has the potential to increase participants' awareness of environmental infrastructure and the connection to community impacts and stem-related careers. the proposed workshop squarely addresses agu's **\*\*diversity\*\*** and inclusion strategic plan including to 1) ?promote and expand collaborative activities... with local community?relevant scientific endeavors, particularly in support of under-served and disadvantaged communities? and 2) ?increase the visibility of education and career paths (in earth science) among diverse audiences and encourage participation in the geosciences.? program participants will develop creative content for presentation at the 2020 agu virtual fall meeting - including virtual tours, videos, and interactive communication pieces to demonstrate how new orleans', san francisco's and los angeles' unique

geology and seaport locations impact the critical infrastructure of those cities and respective communities. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Developing Institutional Responsible Conduct of Research Training Plans that Reflect Best Practices

Awardee: University of California-Riverside

Amount: \$46,807.00

Abstract: the workshop is designed to identify and share best practices in the implementation of robust educational programming for responsible and ethical conduct of research [recr]. the workshop will focus on the achievements of peer model institutions and identify best practices for successful implementation at other institutions. by directly addressing common hurdles that institutions face and building on what has been successful, this workshop will produce a roadmap of resources and guidelines which can be widely distributed and adopted, as appropriate, across a **\*\*diversity\*\*** of other institutions. the outcomes will directly contribute to enriching recr programming and program implementation to support the progress of science by fostering responsible and ethical research. educators, university administrators, industry and scientific communities will be interested the outcomes of this workshop. this workshop will focus on 1) examining the elements that need to be addressed in an institutional recr plan, 2) identifying the key challenges and barriers to the creation and implementation of such programming, and 3) exploring strategies for how those challenges might be met. this goal of this workshop is to create a framework of best practices for implementing robust recr programs based on peer models of excellence. representatives from institutions will share opportunities and challenges in the implementation of recr programming on their campuses to find common ground for further exploration of best practices. the workshop will collect and disseminate practical advice for recr implementation that is not otherwise currently

addressed/available. the outcomes will directly contribute to knowledge of recr implementation by providing institutions with key factors and considerations for improving their recr programs based on peer examples of success, something that has not been previously collected or disseminated. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: GeoGaze: Gaze-Driven Adaptive Multimedia to Augment Geoscience Learning for Neurodiverse Learners

Awardee: University of Massachusetts Boston

Amount: \$46,758.00

Abstract: much of learning occurs today in multimedia environments. this project will design and test geogaze, a novel technology that uses eye tracking to augment learning with multimedia in real time. geogaze analyzes and predicts effective strategies for students based on differences in working memory capacity and changes the presentation of learning materials to help everyone view and learn information. investigators will first study what visual attention strategies work best for learners with different levels of working memory capacity. this information will be used to build a gaze-driven technology to help each learner use the most effective strategies by adapting the learning materials in real time and for each learner. examples of this include predicting where learners will look on the screen, what order they will explore the content, and then highlighting the most important elements in the sequence to be viewed or blurring the less relevant content before revealing when appropriate. the results of this project will help us understand how individual differences in visual attention and working memory capacity influence multimedia learning and how to adapt learning materials to improve learning in real time. this project seeks to engage more students in learning geoscience, a field not well represented by a **\*\*diversity\*\*** of students and researchers. studies of multimedia learning traditionally focus on final learning outcomes but what

happens during the learning process (e.g., visual attention strategies to integrate multimedia) is often unexplored. this project addresses these shortcomings to gain a robust perspective of how students with different working memory capacities learn authentic stem content (geoscience) in multimedia environments, and how their cognition can be enhanced using gaze-driven adaptive learning technology, geogaze. this approach is based on a novel integration of behavioral and psychophysiological data as well as multi-layer backpropagation neural network analysis to predict media integration strategies. geogaze represents a novel gaze-driven technology for adapting multimedia learning in real time based on effective media integration strategies for each learner. this research will generate new empirical evidence for using real-time gaze-driven adaptation of learning materials to augment cognition and improve learning. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: A Professional Learning Community for Advancing Community College Education and Student Success (ACCESS)

Awardee: University of California-Berkeley

Amount: \$46,575.00

Abstract: the university of california berkeley museum of paleontology (ucmp) will lead a one-year virtual conference to establish a professional learning community (plc) of community college instructors and graduate students to support the development of teaching resources for diverse audiences. the plc builds upon existing partnerships with community colleges and resources developed as part of the access (advancing community college education and student success) program to make the geosciences and practices of scientific inquiry more accessible to all learners. while earth science literacy and perspectives from diverse stakeholders are essential for addressing 21st century societal and environmental challenges, the geosciences remain one of the least

diverse stem disciplines. by partnering with community colleges, the program will serve students who identify as low-income, first-generation, or underrepresented minorities. the access program is uniquely positioned to help enhance online and in-person geoscience learning experiences for students while simultaneously helping community college instructors and uc berkeley graduate students develop inclusive pedagogical practices to enhance their teaching skills. the access plc will support the revision and implementation of inquiry-based lessons for diverse audiences using active, equitable, and inclusive learning practices known as model-based inquiry. through a year-long series of workshops and meetings, the plc will develop lessons that deepen students' understanding of the earth history and processes, which is necessary to contextualize the complexity and urgency of global climate and local environmental challenges. efforts to enhance stem education that focus on issues related to **\*\*diversity\*\*** and inclusive practices are typically one-time efforts and not a continual means of providing professional development and support for instructors. year-long support for instructors and iterative development of resources in the ucmp access plc will help transform and sustain shifts in teaching practices as we face the ongoing challenges of providing online and blended learning experiences for students. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Varieties of Crises, Elite Responses, and Executive Approval

Awardee: Indiana University

Amount: \$42,019.00

Abstract: this award is funded in whole or in part under the american rescue plan act of 2021 (public law 117-2. this project examines four major types of crises -- economic, security, natural disaster, and public health crises ? and how they influence public support for political leaders in contemporary democracies. this is important to understand because leader approval is a key barometer of policymaker accountability and democratic stability, both of which can be undermined by crises. this project analyzes the interplay of four factors which vary systematically across these different types of crises and how, in turn, these shape public evaluations of political executives: (1) the ability of citizens to assign responsibility for policy decisions and outcomes; (2) the degree of expert consensus on effective policy response; (3) how much a given crisis in one area generates acute challenges or crises in other areas; and (4) the extent to which an effective response depends on citizens acting collectively. several data sets including (quarterly) measures of executive approval and crises; the tone and salience of leader messaging about the crises; the media's treatment of leader messaging; and (monthly) leader approval for a smaller number of countries for which such data is available; and survey-based experiments in three countries are collected and made publicly available. the award supports education and **\*\*diversity\*\*** by building the research capacity of a student project lab at georgia state university, a minority serving institution, in coordination with pis at four other universities who will also engage graduate and undergraduate students in this work.

puzzling divergences across countries in public reactions to leader responses to the covid-19 public health crisis have revealed major gaps in our understanding of how crisis events translate into public assessments of leaders. to resolve these puzzles, this project advances a unifying theoretical framework that identifies four major types of crises: economic, security, natural disaster, and public health. it then locates these crises on four key dimensions which should condition public support of top officials: the institutional and political context and other factors that impact attribution of responsibility, degree of expert consensus and incentives for politicians to follow expert recommendations, the likelihood and nature of spill-over to other crisis types, and the degree to which citizen action is required for an effective response. the project collects data to test

theoretically-motivated hypotheses using: 1) a macro time-series cross-national data set to study the effects of crisis type on public approval for political executives for 48 countries, 2) a high-frequency time-series data set appropriate to test how approval dynamics reflect leader responses, as well as messaging choices and media effects for 18 countries for which this data is available, and 3) conjoint experiments in france, italy, and mexico, countries with different political and institutional settings, to assess the validity of the links between crisis types and dimensions as well as to validate proposed individual-level mechanisms. this project is supported by the accountable institutions and behavior program and the sbe build and broaden program. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: EAGER: Scaling Necessary Change, Coalitions and Community (SNC): brave leadership for better geoscience"

Awardee: Amherst College

Amount: \$41,819.00

Abstract: in 1972, geoscientist dr. randolph bromery chaired the "first national conference on minority participation in earth science and mineral engineering", a gathering of more than 300 representatives of academia, industry, government, and civil rights organizations. the goal of the conference was to broaden participation and support the success of black, native, and latinx geoscientists. despite this goal, the geoscience community remains a long way from achieving the level of \*\*diversity\*\* needed to tackle some of the nation's most pressing environmental challenges. this project will develop a scholarly, community-driven, forward-looking roadmap that institutions, funding agencies, industry, and the public can use to contribute to the universally beneficial goal of broadening participation in the geosciences over the next half century. training a diverse cohort of geoscientists is essential to meeting the growing demands for a robust geoscience workforce that

can address the societal challenges posed by natural hazards, global change, and energy in the 21st century. however, historical efforts to advance this goal have been ignored or forgotten among most geoscientists, the scientific community, and the broader public. to make substantive and lasting demographic change in the geosciences, the research community must understand past efforts to advance justice and use them to inform new ways forward and to establish mechanisms for accountability over the next fifty years. to develop the roadmap report, this project will first convene the geoscience community at a "second national conference" to examine the past fifty years of efforts to advance broadening participation in the geosciences. following the convening, the project will form a group of twenty early-career geoscientists that will co-author and deliver the roadmap report. this project has a novel approach as early-career scholars usually are not in the leading role of such large community-wide efforts. the project leads and the twenty-person writing team will be early career professionals. if successful, this project will provide the new and innovative ways forward towards achieving more justice, equity, **\*\*diversity\*\***, and inclusion in the geosciences.

this project advances a radically new strategy, centered on brave leadership, to achieve broadening participation goals in the geoscience community. by drawing on tenets of black studies and other frameworks from social science and humanities, this project will take a novel, interdisciplinary approach and establish evidence and experience-based strategies for broadening participation that expand the understanding of the history, current state, and future of geoscience. to ensure that progress is made on reaching the goals for broadening participation in the coming decades, the geoscience community needs a roadmap that will provide checkpoints, strategies, and accountability. to create this roadmap, principal investigators (pis) will (1) convene a conference with participation from stakeholders, representatives, and leaders across academia, industry, professional organizations, and government agencies. participants will reflect on past efforts to advance geoscience goals and cultivate partnerships to support new institutional and community goals. then, pis will (2) identify a team of twenty early-career leaders to develop "the 2072 report". developing the report will be a unique professional development experience that will equip the next

generation of geoscience leaders with tools, frameworks, and partnerships necessary for making lasting change in the field. this project has a novel approach as early-career scholars usually are not in the leading role of such large community-wide efforts. the project leads and the twenty-person writing team will be early career professionals. if successful, this project will provide the new and innovative ways forward towards achieving more justice, equity, **\*\*diversity\*\***, and inclusion in the geosciences. a primary outcome of this work will be the co-creation of a community-driven framework for achieving a just, diverse, and equitable geoscience community. it will include best practices, tools, and ideas for broadening participation; checkpoints and goals that will keep the community on track; and strategies for ensuring accountability over the next fifty years. this roadmap will provide the geoscience community with direct opportunities for reflection on what can be achieved in two years, what is feasible in a five- or ten-year strategic plan, and how those components can provide building blocks towards fundamental, sustainable, systemic change. another outcome will be the establishment of a cohort of early-career geoscientists who are committed to dedicating their careers to transforming the geoscience landscape while they pursue academic positions. this will encourage novel and interdisciplinary research directions across geosciences. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: 2022 CONFERENCE: A Workshop on Undergraduate Research for Faculty in Glass Science and Engineering (Cedar Rapids, Iowa)

Awardee: Coe College

Amount: \$40,876.00

Abstract: this workshop is supported by three programs: condensed matter physics (cmp), metals and metallic nanostructures (mmn), and ceramics (cer). non-technical description: this multiday workshop in may 2022 serves to encourage faculty who work with undergraduates to conduct

research in glass science and engineering. best practices are discussed and include what are suitable projects, funding opportunities and writing proposals, collaborating with r-1 institutions, and how research is best carried out with undergraduate students in the summer and in the academic year. building a diverse workforce in the field has high value. thus, various aspects of **\*\*diversity\*\*** and undergraduate research are discussed including its inherent importance, recruitment of diverse scholars, and encouragement and mentoring. follow-up with the faculty members participating in the workshop is taking place to ensure that the goals of undergraduate research are being reinforced. one important broader impact is that many coe college undergraduate students, with research experience, consistently over time enter graduate school and industry in the field at rates approaching 75%. technical details: there is a documented need for more glass scientists and engineers. a key element that encourages undergraduate students, in general, to engage at a high level is involvement in publishable research. this workshop, at coe college, involves twenty faculty who are working with undergraduates in glass science and engineering. the workshop is led by professors feller and affatigato and several nationally known experts in research with undergraduate students and **\*\*diversity\*\***. at coe college, nearly 400 students who perform publishable research enter the field in industry and graduate school at about the 75% level. this impact occurs while simultaneously increasing **\*\*diversity\*\***. workshop participants are benefitting from well over 100 years of hands-on experiences by the presenters. a transformational aspect of the activity is the multiplicative effect of having a large cadre of faculty geometrically increasing student involvement in the field at the undergraduate level. documentation of these efforts take place by presentations at meetings of the american ceramic society, the iowa glass conference, and the international congress on glass. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: 3 Myr of Laurentide Ice Sheet History Inferred from Cosmogenic Nuclides in Ice-Rafted Debris

Awardee: Purdue University

Amount: \$38,150.00

Abstract: the laurentide ice sheet over north america caused large changes in climate and sea level as it grew and shrank over ice age cycles during the past three million years, but little is known about the ice sheet's detailed history throughout this interval. this project will determine how big the ice sheet was through time using chemical markers in layers of sand on the seafloor that melted out of icebergs drifting from north america. this method provides a new way to learn about past changes in the laurentide ice sheet and test ideas for how climate change and ice sheets affect each other. the results should help with predictions of sea-level rise far into the future due to global warming and melting polar ice sheets. this project will also educate and involve a wide range of people in climate science in several ways. videos about the research will be sent to boston public schools through the bostem organization to help students in the area learn about careers in science. the researchers will participate in activities through the mcauliffe center for integrated science learning at framingham state university to teach middle and high school students and teachers about climate change. college students will help with the research during summers through the integrated science for society nsf research experience for undergraduates at boston college, which tries to find students from underrepresented minority groups or who are the first in their family to go to college and that do not have research possibilities at their school. lastly, the project will support a female ph.d. student already at boston college and an m.s. student at the university of vermont. the laurentide ice sheet over north america was one of the largest drivers of climate and sea level over the ice age cycles of the past three million years, but its history over this interval is shrouded in uncertainty largely due to limitations of conventional geologic records. this project will take a new approach, measuring the concentrations of rare chemicals in quartz sand layers from ocean sediment cores that melted out of drifting north american icebergs. the chemistry of the sand reflects the history of

north american ice sheet cover because the chemicals accumulate in land surfaces exposed to the atmosphere but radioactively decay away when the surfaces are buried by ice. four sediment cores will be analyzed to reconstruct long-term laurentide ice sheet evolution, and analyses of sand samples collected across eastern canada will show how their chemistry records ice sheet variations over the most recent ice age cycle. together with similar reconstructions produced over the past five years from greenland and antarctica, these records will provide a comprehensive picture of how these three ice sheets varied in the past and contributed to global sea level. the results will offer much-needed constraints to test theories and models of paleo-ice sheet change, useful for improving long-term future projections of ice sheets on earth today. this project will increase literacy and **\*\*diversity\*\*** in climate science in multiple ways. ?science bites? videos about the research will be distributed to boston public schools through bostem to demystify careers in science. participation in ongoing efforts through the mcauliffe center for integrated science learning at framingham state university will help educate middle and high school teachers and students on climate change. this project will support an existing female ph.d. student at boston college and an m.s. student at the university of vermont. summer undergraduate research assistants will be recruited through the integrated science for society nsf reu at boston college, which seeks to attract underrepresented minority and first-generation college students from schools with limited research opportunities. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Building consensus around the quantification and interpretation of Symbiodiniaceae diversity

Awardee: William Marsh Rice University

Amount: \$35,394.00

Abstract: single-celled microorganisms are highly diverse and play various roles in the function of

natural ecosystems, but it is challenging to recognize how genetic, morphological, and physiological **diversity** relate to each other in microbial groups. In an exemplary case, micro-algae in the family Symbiodiniaceae comprise many species that can only be distinguished using molecular data. Symbiodiniaceae function as symbionts of various marine invertebrates, but are perhaps best known as the key to coral reef ecosystem health and persistence. The team is hosting a virtual workshop in August 2021 to identify and build further consensus among experts regarding the assessment of Symbiodiniaceae **diversity**. By formalizing consensus approaches and disseminating them broadly, this workshop is creating a more collaborative and welcoming research community and ensuring that all current researchers, as well as those entering the field, feel confident applying for grants, conducting research, and publishing papers that incorporate work on Symbiodiniaceae **diversity**. This workshop is defining additional forward-thinking research priorities that anticipate methodological advances over the next 5-10 years.

Resolving the molecular **diversity** of microorganisms is a major technical challenge, particularly for dinoflagellates in the family Symbiodiniaceae. These micro-algal endosymbionts that associate with corals and other marine invertebrates feature massive genomes, high repeat content, and other unique aspects that have hindered their molecular characterization. As sequencing technologies have advanced, so too has our understanding of Symbiodiniaceae **diversity**, which has grown from the presumption of one widespread species in the 1960s to now encompass fifteen divergent genera and likely hundreds of species. This process of discovery has been fraught with controversy, as the most useful phylogenetic marker, the hyperdiverse internal transcribed spacer 2 (ITS2) region, is frustratingly difficult to interpret in a consistent manner. The ribosomal array is multicopy, it evolves at different rates in different lineages, and it is subject to concerted evolution, all of which complicate phylogenetic reconstructions. Moreover, sampled coral tissues contain populations of symbiont cells that can potentially be from multiple Symbiodiniaceae taxa, complicating efforts to characterize partner specificity. Early debates focused on the extent to which unique ITS2 sequences indicated the presence of multiple symbiont species or simply multiple intraspecific variants. This central conflict

has led to different schools of thought about how flexible coral-algal associations can be, and how they might respond to ongoing climate change. next-generation sequencing has provided more data, but the same foundational interpretive issues remain. this team is gathering pioneering symbiodiniaceae experts from around the world (ranging from seasoned veterans to newly-minted phds) who all collectively agree that a consensus interpretive framework can and must be identified and advanced in order to move the field forward. the participants are generating a ?consensus road map? leading to two workshop products: 1. an nsf white paper; and 2. an open-access, peer-reviewed manuscript. through pre-workshop surveys, four workshop sessions, post-workshop collaboration, and publication, the team is summarizing current practices and recommending key methods for identifying and analyzing symbiodiniaceae genetic **\*\*diversity\*\*** across three ?umbrellas?: 1. communities, 2. populations, and 3. strains. the written products from this workshop are being distributed to the wider reef and conservation community by leveraging a separate mini-workshop previously developed for the 2022 international coral reef symposium. workshop participants are also highlighting new technologies and research priorities for the next decade that should help fill some of the remaining knowledge gaps. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Island Population Responses to Environmental Stresses

Awardee: Florida International University

Amount: \$35,000.00

Abstract: large and unpredictable stressors like new diseases are impacting practically all species with increasing frequency and strength. understanding how species respond often relies on studies of genetics. islands are a good place to study such responses because a large fraction of resident species are usually impacted. the covid pandemic has disrupted the ability of many students ? especially those from underrepresented groups -- to get the training and mentoring they need to study genetic responses to stressors. this workshop will help fix that problem by providing students

from puerto rico and southern florida with cutting edge skills for analyzing and interpreting genetic data that they may find challenging. the workshop will help ensure the continued academic progress of participants from stem underrepresented communities by engaging them in research activities that can be undertaken when most laboratory and fieldwork is limited. workshop participants will acquire skills to analyze gene expression data from their independent research projects on response of organisms across the span of biological **\*\*diversity\*\*** to biotic and abiotic stressors. a high degree of ?hands-on? virtual interaction between participants and instructors will be used as a platform. this will be followed with email and chat group communications and coupled with posted recorded sessions and associated supporting instructional materials. results are likely to yield new insights about how organisms adapt to new environmental challenges. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: LTREB Renewal: Long-Term Dynamics of Amphibian Populations Following Disease-Driven Declines

Awardee: University of Tennessee Institute of Agriculture

Amount: \$34,837.00

Abstract: this project will examine the processes of invasion of a novel pathogen into a population for the case of a fungal pathogen that causes the disease chytridiomycosis in frogs and salamanders. outbreaks of emerging infectious diseases are increasingly recognized as major threats, not just to human populations but also to wildlife, and they increasingly threaten global bio**\*\*diversity\*\***. the initial invasion of a novel pathogen into a susceptible host population can cause a disease outbreak resulting in high levels of mortality and declines in population size. when this happens, natural selection can occur for both the host and pathogen populations resulting in evolutionary changes in the host's susceptibility and tolerance to infection by the pathogen and the

pathogen's ability to damage the host (virulence). these changes can in turn determine whether the host population can persist and recover from the disease. understanding these evolutionary processes is crucial in development of conservation strategies for threatened species. chytridiomycosis has had catastrophic effects on amphibians worldwide, and has been linked to numerous species extinctions in recent decades and many more species at risk. the researchers will investigate the patterns of evolutionary change in both the pathogen and the host (mountain yellow-legged frogs), following the invasion of the disease into hundreds of high elevation lakes in the california sierra nevada. this project will contribute to the understanding of the role of infectious diseases, such as chytridiomycosis, as agents of evolutionary change in natural populations. it will provide critical information to state and federal agencies, facilitating endangered species recovery and will train and educate undergraduates, graduate students, and the general public. this research builds on data from a long-term study of the population dynamics of mountain yellow-legged frogs (*rana sierrae* and *rana muscosa*) in the complex landscape of the california sierra nevada, and the affects of *batrachochytrium dendrobatidis* (bd) as it has invaded and spread through hundreds of frog populations. in most cases, invasion of bd results in outbreaks of the disease chytridiomycosis, rapid frog population declines, and local extinctions. in some cases, long-term persistence of frog populations occurs with bd in an enzootic state in which the impact of the pathogen is greatly reduced. the research will extend and leverage 25 years of host population and disease data and archived genetic samples from *r. sierrae*/*r. muscosa* and bd. these resources will provide insight into how populations of both host and pathogen change during the transition from pre-pathogen arrival, to disease outbreak, to enzootic disease, to potential recovery of the pre-disease host population abundances. this dataset will be used to investigate the genetic basis for differences in host resistance/tolerance and pathogen virulence. cutting-edge genomic analysis of existing frog and fungal samples will complement laboratory experiments on bd virulence and frog susceptibility using bd cultures and frog mucosal samples from wild host populations. continued surveys of wild host populations will identify new disease outbreaks and describe the transition from

initial outbreak to persistent enzootic state. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Tackling Functional Protein States at Atomic Detail by Integrating Weighted Ensemble Simulations with Magnetic Resonance Restraints

Awardee: Carnegie-Mellon University

Amount: \$34,334.00

Abstract: this project is designed to characterize the alternate structures of proteins?the workhorses of life whose functions in biology are determined by their structures. a major challenge to characterizing these so-called ?functional structures? is that these structures are often too diverse or fleeting to be captured by experimental techniques at the level of individual atoms. an unmet need is therefore a strategy that can determine the structures of functional protein structures at the atomic level and even more crucially, a strategy that can provide insights into how the functional structures interconvert. this project will develop a new software tool that can determine the functional structures of proteins, how the proteins move to convert from one structure to another, and the rates at which the structures interconvert. this tool combines the use of computer simulations with distances within proteins that are measured by experiments and will be made available through a popular, freely available westpa simulation software package. this interdisciplinary, collaborative project is providing a valuable training ground for graduate and undergraduate students participating in the research, and is supporting diverse educational and outreach activities, including biennial westpa software workshops to provide training to the scientific community in using the new tool for determining the functional structures of proteins. a new frontier in biophysics has been the structural characterization of protein functional states. proteins are the workhorses of life and their functions are determined by their structures. a major challenge to characterizing protein structures is

that many proteins adopt not just a single structural state, but alternate states that are relevant to the biological functions of the proteins. due to the **\*\*diversity\*\*** and often transient nature of such functional states, the determination of their structures at the atomic level has been elusive to experimental techniques. an unmet need is therefore a strategy that can generate atomically detailed structures of functional states, and even more crucially, a strategy that can provide detailed insight into the pathways for interconversion between the states and corresponding kinetics. a key advance of the project is the development of a general strategy that integrates sparse distance restraints from magnetic resonance experiments with rigorous simulations to provide atomic level structures and dynamics of functional protein states. this project will provide a new simulation tool that will be made available to the scientific community through the freely available westpa software. to further enhance the accessibility of the software, the westpa software will be integrated with the orion cloud-computing platform on amazon web services, the world's largest on-demand, cloud-computing facility. this project is funded by the molecular biophysics cluster in the division of molecular and cellular biosciences, with partial co-funding from the chemical measurement and imaging program in the division of chemistry. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: EAGER: Collaborative Research: Towards an Extensible Internet

Awardee: Mount Holyoke College

Amount: \$34,295.00

Abstract: the internet's basic design has remained largely unchanged since it first became commercial in the 1990s. now that the internet is the centerpiece of our global communications infrastructure, it is essentially impossible to alter its design in any significant way. unfortunately, such changes are needed to improve the internet's performance and security. this project aims to resolve

this paradox with a design called the extensible internet. this is a collaborative project which brings together investigators from mount holyoke college, new york university, the university of washington, and international computer science institute at the university of california at berkeley. in today's internet, layer 3 has two basic functions: (i) connect all layer 2 networks and (ii) provide the packet delivery services on which host applications are built. the key aspect of the extensible internet is that it splits layer 3 into two layers. the first, which remains layer 3 and can use the current internet protocol (ip), handles the first function of connecting layer 2 networks. the second requires a new layer (called layer 3.5) that supports an extensible set of packet delivery services, and thus handles the second function of providing the services on which host applications are built. in this way, the extensible internet design leaves the current internet unchanged but is able to provide an extensible set of new packet delivery services that will improve the internet's performance and security. the extensible internet design is incrementally deployable (i.e., no unchanged applications or domains would lose connectivity), compatible with economic incentives, and can continue to evolve as new requirements arise. as such, it provides a practical way for the internet to evolve far beyond its current design. if the extensible internet design is adopted, it would have a significant impact on the nature of the internet. in particular, transitioning to the extensible internet is not just a one-time change in functionality, but transforms the internet from a single and unchanging service model (best-effort packet delivery) to an evolving and expanding set of network-provided services. in addition, in pursuing this agenda, the investigators will work to increase the **diversity** of the stem workforce through ongoing efforts in their own research groups and the outreach programs in their respective departments. the investigators will also incorporate their results into their courses and make the material freely available. all of the code from this project will be available on the project's website at [extensibleinternet.org](http://extensibleinternet.org). this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: GP-UP: A near surface geophysics field experience to improve the recruitment and retention of under-represented minority students in the geosciences

Awardee: Dickinson College

Amount: \$32,834.00

Abstract: this award is funded in whole or in part under the american rescue plan act of 2021 (public law 117-2). undergraduate geoscience education in the united states lags behind other science, technology, engineering and mathematics (stem) fields when it comes to racial and ethnic **\*\*diversity\*\***. this deficit is particularly notable for students who come from communities that have been historically excluded in stem fields and translates to a larger gap in the workforce and at the graduate level. notably, there has been no improvement in the racial and ethnic **\*\*diversity\*\*** of students earning doctoral degrees in the geosciences over the past 40 years. research has shown that **\*\*diversity\*\*** has demonstrated benefits for scientific advancement, including that diverse perspectives provide unique approaches to problem solving; these perspectives are necessary to meet the challenges and to solve the complex problems of the geosciences. to address this gap, the pis have designed a field program: ?geophysics of the near-surface: an outdoor motivational experience for students? this project aims to inspire students to major in the geoscience and help these students develop some of the workplace skills necessary to succeed in geoscience careers. the project will provide an engaging outdoor field experience for the student participants that will influence their choice of major, provide mentorship opportunities for upper-level undergraduates, create positive and lasting student-student and student-faculty mentor relationships, provide meaningful research experiences for the students, and create a strong cohort of students across multiple institutions. the goals of the program are: (1) recruit a diverse cohort of undergraduate students; (2) support student learning in critical zone science and geophysics; (3) increase students? science communication, problem solving, teamwork, and leadership skills; (4) enhance psychosocial factors that are linked to retention in stem fields; (5) increase participation in

geoscience research; (6) increase positive attitudes towards geoscience careers and research; (7) increase mentors? leadership and professional skills. by attaining these goals, the pis propose to build a geoscience learning community of students across the participating institutions and within the broader scientific community and will increase recruitment and retention of these students in geoscience degrees and careers. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: REU Site: Collaborative Research: Research Opportunities in Rock Deformation

Awardee: University of Minnesota-Twin Cities

Amount: \$32,208.00

Abstract: rock deformation, a sub-discipline of earth science, uses geology and engineering methods to measure the strength of rocks. information about rock strength can be applied to a wide range of problems in engineering, natural hazards, and material science, as well as geology. however, very few scientists specialize in the field of rock deformation; thus, many important research questions remain unexplored or underexplored, slowing advances in science and engineering. geoscience departments at primarily undergraduate or primarily minority-serving institutions often do not have active rock deformation research programs and labs that deal with rock deformation are relatively rare. this reu site aims to increase access and exposure of a diverse population of students to career opportunities in this area. the project offers undergraduate students the unique opportunity to conduct summer research at one of eleven state-of-the-art, experimental rock deformation labs across the country. experts in rock deformation will serve as mentors to a cohort of 10 students each summer. this reu site provides access and training, professional and career development activities, and robust workforce development for students from all backgrounds.

the reu site will provide research and mentorship opportunities for undergraduate students in the

field of experimental rock deformation. the long-term objective is to increase the number and **\*\*diversity\*\*** of students pursuing research or industry careers in rock deformation. student participants will receive training in research methods and professional development topics that will provide a stable foundation for graduate school or related career paths. a large team of pis and senior participants ensures that students who participate in the program will have a deep professional network to support their future endeavors. students will be drawn from the full spectrum of higher education institutions. strong emphases will be placed on recruiting students from diverse and under-represented backgrounds, and smaller colleges and universities that do not have research programs in rock deformation. the reu site will include three integrated sessions: a field session to introduce students to the geological study of deformed rocks, a laboratory session where students conduct experiments on specimens collected during the field session, and a conference session where students can present the results of their research projects. the reu site will adopt a distributed model, leveraging the combined lab capacity of the pis and other senior participants to support 10 students per year. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: CAREER: Memory-Efficient, Heterogeneity-Aware and Robust Architecture for Federated Intelligence on Edge Devices

Awardee: George Mason University

Amount: \$31,592.00

Abstract: the recent trend of migrating computation from the centralized cloud to distributed edge devices is reshaping the landscape of today's internet, especially under the unprecedented challenges of the covid19 pandemic. with privacy being a critical concern in data aggregation, federated learning emerges as a promising solution to such privacy-utility challenge. it pushes the computation towards consumer's edge devices, where the data is generated. by exchanging statistical information, the participants perform collaborative learning in a distributed fashion. unfortunately, the original design still faces new system-architectural challenges from limited memory, software/hardware heterogeneity, security and statistical **\*\*diversity\*\*** from different edge devices. the overarching goal of this career project is to design, optimize and implement a memory-efficient, heterogeneity-aware and robust architecture for federated learning on consumer's edge devices. in particular, it aims to: 1) remove the memory barriers of running the computational-intensive learning tasks; 2) resolve the software and hardware heterogeneity among various kinds of devices; 3) secure the information exchange and the machine learning backend. the research will provide a stack of solutions to address the urging needs in realizing collaborative intelligence on edge devices with computation/memory/energy-efficiencies, security and robustness.

this research will address an urgent problem to bridge the gap between the vast data available from consumer's edge devices and the rising interest of utilizing such private data to improve our wellbeing. the algorithms and tools developed in this career project will lay the foundations to a plethora of new applications on massively distributed edge devices, as the essential elements for building a smart, connected and resilient community. the career program will advance stem education by developing new educational components related to machine learning, edge computing

and security. this includes diverse outreach plans of cybersecurity summer camps, junior research symposium, high school instructor mentorship, coding competitions and the inclusion of underrepresented minority and women engineers. the potential use cases will be also explored with the collaborating industrial partners to enrich their business models. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Doctoral Dissertation Research: The effects of forest habitat modification on hunting and prey abundance

Awardee: Ohio State University

Amount: \$31,500.00

Abstract: this award is funded in whole or in part under the american rescue plan act of 2021 (public law 117-2). the world's rainforest ecosystems are hotspots of global bio\*\*diversity\*\* and have extensive histories of occupation by indigenous peoples as locations for customary agriculture and subsistence foraging and hunting. with these reservoirs of bio\*\*diversity\*\* now showing signs of decline, we require a better understanding of how human-influenced forests can both support indigenous livelihoods and sustain diverse floral and faunal communities. while human use and modification of rainforests has historically been thought of as a potential driver of species loss,

recent research suggests that forest mosaics created by human activities harbor a substantial degree of habitat **diversity** and novel foraging opportunities that may benefit animal and plant communities. the purpose of this doctoral dissertation project is to study the relationship between customary agricultural practices and subsistence hunting to understand how these practices impact local faunal and floral **diversity** in a neotropical rainforest. in addition to training a doctoral student in anthropological science, the research helps local stakeholders manage natural resources and generalize these insights so they can be used to develop management designs that incorporate local practices to prevent wildlife loss. the central research question of this dissertation project is whether the human-influenced forests that are created by customary agriculture can support populations of wild game and enable sustainable harvests of wild game by subsistence hunters. the researchers test whether and how human disturbance precludes or facilitates resource conservation. integrating theory and methods from human behavioral ecology, wildlife management, and community ecology, this research documents hunter movements and harvest returns and links them to patterns of wildlife abundance along a disturbance gradient created by customary agricultural practices. the researchers use semi-structured interviews and participant observation to ethnographically contextualize the social and ecological dimensions of customary agriculture and subsistence hunting. by studying how humans and wildlife select and use habitat in a mosaic of cultivated, secondary, and climax forest, this study contributes theoretical insights about the mechanisms for sustainable harvest of wild game species and the coexistence of ecological communities with human communities. rather than study hunting and farming as distinct forms of human-environment relations, this study conceptualizes these practices as key parts of an integrated socioecological system. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Conference on Homological Commutative Algebra and Related Topics

Awardee: Georgia Southern University Research and Service Foundation, Inc

Amount: \$30,000.00

Abstract: this award funds the research conference "homological commutative algebra and related topics and their applications." this international conference will be held at georgia southern university's armstrong campus in savannah, georgia during may 13-15, 2022. the main goal of the meeting is to bring together a diverse group of researchers from a mixture of fields, and in different stages of their careers, in a forum where they will be able to exchange and build on their mathematical ideas and work. in particular, the conference will highlight the recent results and developments in homological commutative algebra and will further connect with several fields of mathematics, including combinatorics, geometry, number theory, and others. the event will include established and early-career mathematicians, as well as post-doctoral fellows and students, allowing collaborations, networking, and professional development between these different groups. special care will be taken to ensure participation from women and researchers in underrepresented groups to enhance and promote **\*\*diversity\*\*** and inclusion in the mathematical sciences. the expected outcome is to support and promote these mathematical topics for students and researchers in the southeastern region and beyond. homological algebra originated from algebraic topology as a tool used in the commutative algebra localization conjecture of regular local rings. subsequently,

homological algebra has become a major subdiscipline of commutative algebra. the conference activities will address many connections between homological commutative algebra and other mathematical disciplines. specifically, the event includes discussions on fundamental problems in commutative algebra, algebraic geometry, algebraic number theory, representation theory, combinatorics, deformation theory, category theory, rational homotopy theory, and other related areas. it will follow a typical format with research talks in conjunction with collaboration opportunities, and it will feature a mix of 50-minute research talks given by established mathematicians and 25-minute presentations from early-career researchers. for more information, see [the conference webpage](https://sites.google.com/georgiasouthern.edu/commutative-algebra-conference/home) <https://sites.google.com/georgiasouthern.edu/commutative-algebra-conference/home> this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Enhancing Diversity in Graduate Education: Research Results from More than Twenty Years of Empowering Women in Mathematics

Awardee: University of Wisconsin-Eau Claire

Amount: \$30,000.00

Abstract: this award supports participation of graduate students, postdoctoral researchers, and early-career faculty in the session titled "the edge (enhancing **diversity** in graduate education)

program: pure and applied talks by women math warriors? at the 2022 and 2023 joint mathematics meetings (jmm). the 2022 jmm session will be held in seattle, washington and the 2023 jmm session will be held in boston, massachusetts. the edge program was founded in 1998 to improve retention and completion rates for women and minorities in graduate programs and increase **\*\*diversity\*\*** in the mathematics community. the 2022 and 2023 sessions will showcase the research of women who are affiliated with the edge program. the session provides a platform for women in all areas of mathematics to present their research findings and generate ideas for new research techniques and directions. opportunities to strengthen participants' network of women mathematicians and establish new mentoring relationships with other women affiliated with the edge program are provided. the session benefits the larger mathematics community by increasing the visibility of women in mathematics by highlighting their research work, thereby creating opportunities for recruitment and retention of women in mathematics. further information about the edge program can be found at the link below. Title: Collaborative Research: Mass transport in Mass transport in the Jupiter magnetosphere: driven by internal # or external processes?

Awardee: University of Colorado at Boulder

Amount: \$30,000.00

Abstract: the sun emits a stream of particles called the solar wind. the solar system presents a wide variety of obstacles to the solar wind in the form of planetary magnetospheres. magnetospheres arise from the internal magnetic field of a planet and serve to deflect the solar wind from the surface of the planet. mass from the solar wind hits the magnetosphere and is diffused toward the poles and then carried out behind the planet in a structure called the magnetotail. io is a moon of jupiter that

also provides particles to its magnetosphere from within, and so it can be used to trace the flow of particles from within the magnetosphere. this project will use observations of sulfur and sodium ions to trace out the diffusion of particles from within jupiter's magnetosphere to better understand the process of diffusion in magnetospheres. the project will use a dedicated telescope for their observations. the project will also create a children's book, 'the misfit telescope' with a companion website and social media stream that use the benefits of \*\*diversity\*\* in scientific instrumentation as a parable to illustrate the benefits of racial and cultural inclusivity. the proposed project will study the io plasma torus (ipt) around jupiter in order to gain insight into the jovian magnetic field. the project will use the io input/output observatory to make time domain observations of s ii and na lines in the ipt to determine the nature of diffusion of material. ioio is a small-aperture robotic coronagraph that operates nightly, contemporaneously recording narrow-band images of the ipt ins s ii. combined with a model of the ipt, the observations will show whether diffusion is driven by mass loading from io or by activity in the middle jovian magnetic field. the project's children's book will show the value of both being in the minority and havingg a different point of view and of being in the majority and accepting and respecting the minority point of view. the book will be produced by the planetary science institute's award winning public outreach team. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Doctoral Dissertation Research: Paleontological and population genetics approaches for reconstructing hominin evolutionary history

Awardee: Washington University

Amount: \$28,998.00

Abstract: this award is funded in whole or in part under the american rescue plan act of 2021 (public law 117-2). this doctoral dissertation project reconstructs evolutionary relationships among

ancient populations of homo erectus, a pivotal human ancestor, using dental and skeletal data. the project integrates paleontological and population genetics approaches for reconstructing evolutionary history, thereby advancing knowledge about how hominins, including our species, homo sapiens, evolved. the project promotes interdisciplinarity by using approaches typically used in the field of bioarchaeology, increases **\*\*diversity\*\*** in the field of paleoanthropology by supporting the scholarship of a female paleoanthropologist, and fosters international research collaborations. the investigator conducts public and k-12 science outreach through a weblog about human evolution and through science activities with middle and high school students. homo erectus, represented in the hominin fossil record, is morphologically diverse through both time and space. the current understanding of how populations of h. erectus were related to each other is limited. bony and dental anatomy provide the primary basis for assessing evolutionary relationships between populations in the fossil record, but the genetic basis of anatomical traits is not always well understood. this research examines h. erectus temporal and geographic patterns in the relationships among past h. erectus populations using biodistance methods and comparative data. matrices of dental and neurocranial shape distances will be compared separately using mantel tests to a matrix describing the temporal, geographic, or genetic distances between populations. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Building consensus around the quantification and interpretation of Symbiodiniaceae diversity

Awardee: University of South Florida

Amount: \$28,222.00

Abstract: single-celled microorganisms are highly diverse and play various roles in the function of natural ecosystems, but it is challenging to recognize how genetic, morphological, and physiological

**\*\*diversity\*\*** relate to each other in microbial groups. in an exemplary case, micro-algae in the family symbiodiniaceae comprise many species that can only be distinguished using molecular data. symbiodiniaceae function as symbionts of various marine invertebrates, but are perhaps best known as the key to coral reef ecosystem health and persistence. the team is hosting a virtual workshop in august 2021 to identify and build further consensus among experts regarding the assessment of symbiodiniaceae **\*\*diversity\*\***. by formalizing consensus approaches and disseminating them broadly, this workshop is creating a more collaborative and welcoming research community and ensuring that all current researchers, as well as those entering the field, feel confident applying for grants, conducting research, and publishing papers that incorporate work on symbiodiniaceae **\*\*diversity\*\***. this workshop is defining additional forward-thinking research priorities that anticipate methodological advances over the next 5-10 years. resolving the molecular **\*\*diversity\*\*** of microorganisms is a major technical challenge, particularly for dinoflagellates in the family symbiodiniaceae. these micro-algal endosymbionts that associate with corals and other marine invertebrates feature massive genomes, high repeat content, and other unique aspects that have hindered their molecular characterization. as sequencing technologies have advanced, so too has our understanding of symbiodiniaceae **\*\*diversity\*\***, which has grown from the presumption of one widespread species in the 1960s to now encompass fifteen divergent genera and likely hundreds of species. this process of discovery has been fraught with controversy, as the most useful phylogenetic marker?the hyperdiverse internal transcribed spacer 2 (its2) region?is frustratingly difficult to interpret in a consistent manner. the ribosomal array is multicopy, it evolves at different rates in different lineages, and it is subject to concerted evolution, all of which complicate phylogenetic reconstructions. moreover, sampled coral tissues contain populations of symbiont cells that can potentially be from multiple symbiodiniaceae taxa, complicating efforts to characterize partner specificity. early debates focused on the extent to which unique its2 sequences indicated the presence of multiple symbiont species or simply multiple intraspecific variants. this central conflict has led to different schools of thought about how flexible coral-algal associations can be, and how

they might respond to ongoing climate change. next-generation sequencing has provided more data, but the same foundational interpretive issues remain. this team is gathering pioneering symbiodiniaceae experts from around the world (ranging from seasoned veterans to newly-minted phds) who all collectively agree that a consensus interpretive framework can and must be identified and advanced in order to move the field forward. the participants are generating a ?consensus road map? leading to two workshop products: 1. an nsf white paper; and 2. an open-access, peer-reviewed manuscript. through pre-workshop surveys, four workshop sessions, post-workshop collaboration, and publication, the team is summarizing current practices and recommending key methods for identifying and analyzing symbiodiniaceae genetic **\*\*diversity\*\*** across three ?umbrellas?: 1. communities, 2. populations, and 3. strains. the written products from this workshop are being distributed to the wider reef and conservation community by leveraging a separate mini-workshop previously developed for the 2022 international coral reef symposium. workshop participants are also highlighting new technologies and research priorities for the next decade that should help fill some of the remaining knowledge gaps. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Building consensus around the quantification and interpretation of Symbiodiniaceae diversity

Awardee: University of South Florida

Amount: \$28,222.00

Abstract: single-celled microorganisms are highly diverse and play various roles in the function of natural ecosystems, but it is challenging to recognize how genetic, morphological, and physiological **\*\*diversity\*\*** relate to each other in microbial groups. in an exemplary case, micro-algae in the family symbiodiniaceae comprise many species that can only be distinguished using molecular data.

symbiodinaceae function as symbionts of various marine invertebrates, but are perhaps best known as the key to coral reef ecosystem health and persistence. the team is hosting a virtual workshop in august 2021 to identify and build further consensus among experts regarding the assessment of symbiodiniaceae **\*\*diversity\*\***. by formalizing consensus approaches and disseminating them broadly, this workshop is creating a more collaborative and welcoming research community and ensuring that all current researchers, as well as those entering the field, feel confident applying for grants, conducting research, and publishing papers that incorporate work on symbiodiniaceae **\*\*diversity\*\***. this workshop is defining additional forward-thinking research priorities that anticipate methodological advances over the next 5-10 years. resolving the molecular **\*\*diversity\*\*** of microorganisms is a major technical challenge, particularly for dinoflagellates in the family symbiodiniaceae. these micro-algal endosymbionts that associate with corals and other marine invertebrates feature massive genomes, high repeat content, and other unique aspects that have hindered their molecular characterization. as sequencing technologies have advanced, so too has our understanding of symbiodiniaceae **\*\*diversity\*\***, which has grown from the presumption of one widespread species in the 1960s to now encompass fifteen divergent genera and likely hundreds of species. this process of discovery has been fraught with controversy, as the most useful phylogenetic marker?the hyperdiverse internal transcribed spacer 2 (its2) region?is frustratingly difficult to interpret in a consistent manner. the ribosomal array is multicopy, it evolves at different rates in different lineages, and it is subject to concerted evolution, all of which complicate phylogenetic reconstructions. moreover, sampled coral tissues contain populations of symbiont cells that can potentially be from multiple symbiodiniaceae taxa, complicating efforts to characterize partner specificity. early debates focused on the extent to which unique its2 sequences indicated the presence of multiple symbiont species or simply multiple intraspecific variants. this central conflict has led to different schools of thought about how flexible coral-algal associations can be, and how they might respond to ongoing climate change. next-generation sequencing has provided more data, but the same foundational interpretive issues remain. this team is gathering pioneering

symbiodiniaceae experts from around the world (ranging from seasoned veterans to newly-minted phds) who all collectively agree that a consensus interpretive framework can and must be identified and advanced in order to move the field forward. the participants are generating a ?consensus road map? leading to two workshop products: 1. an nsf white paper; and 2. an open-access, peer-reviewed manuscript. through pre-workshop surveys, four workshop sessions, post-workshop collaboration, and publication, the team is summarizing current practices and recommending key methods for identifying and analyzing symbiodiniaceae genetic **\*\*diversity\*\*** across three ?umbrellas?: 1. communities, 2. populations, and 3. strains. the written products from this workshop are being distributed to the wider reef and conservation community by leveraging a separate mini-workshop previously developed for the 2022 international coral reef symposium. workshop participants are also highlighting new technologies and research priorities for the next decade that should help fill some of the remaining knowledge gaps. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Doctoral Dissertation Research: Variation in Island Adaptations

Awardee: Texas A&M University

Amount: \$25,205.00

Abstract: this project will investigate the origins and development of island subsistence-based economies. in this dissertation proposal a case study is presented in which two atlantic islands were likely colonized multiple times by more than one cultural group. the islands also have varying environmental characteristics and human subsistence adaptations. the archaeological study of ancient islanders reveals novel information regarding the many ways in which humans adapt and prosper, as islands present often limited, marginal, and vulnerable landscapes. research on one island shows the arrival of iron age peoples who brought with them grains, herding animals, and

other cultural elements. in addition, recent excavations on the other revealed a roman factory where marine gastropods, stramonita haemastoma, were exploited for commercial purposes to obtain the highly prized royal purple dye. these findings may suggest that the human settlement occurred due to the expansion of ancient seafaring trading networks with the intent to exploit coastal natural resources. archaeology confirms the islands to have been a nexus of cultural exchange and **\*\*diversity\*\***. evidence from ancient material culture, linguistics, and genetics suggest the presence of a heterogenous sociopolitical and economic landscape in the archipelago; however, there is little scholarly consensus as to who exactly peopled the islands and why. a major obstacle to answering these questions is the deficit of reliable chronologies for the entire region ? a problem that will be tackled in this current research by developing a series of radiocarbon chronologies. the project will use stable isotope ratios of carbon, nitrogen, oxygen, and strontium coupled with ancient dna markers from archaeological human remains to better understand local adaptive strategies, social organization, and landscape management methods. the research will address unresolved questions such as the role of coastal resources in the aboriginal economies. through exploring diet and mobility, researchers will deepen into the issue of understanding aboriginal modes of production within such culturally diverse island communities. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Professional Experiences for Students in Plasma Science: Student Travel Support for 2021 and 2022 Gaseous Electronics Conferences

Awardee: University of Alabama in Huntsville

Amount: \$25,000.00

Abstract: this award will support student participation in the 74th annual gaseous electronics conference (gec) to be held october 4 - 8, 2021 in huntsville, alabama and the 75th gec to be held in

late 2022 in sendai, japan. the gec has a three quarter century history in pursuit of the foundational physical and chemical processes occurring in partially ionized, collisional plasmas, encompassing the interactions between atoms, molecules, charged particles, photons, waves, and fields. the gec has a strong tradition of encouraging and promoting student participation. the attendance at research conferences is an important educational experience for students that cannot be replicated at their home institutions. the gec provides opportunities for students to expand their networks both domestically and internationally, to learn about the most cutting edge research and discoveries, and to develop their professional communication skills. the gec is a conference that welcomes student participation and introduces them to the global professional community where they can envision themselves developing their careers. the gec program is organized with breaks mid-morning and mid-afternoon, as a way of facilitating conversation among participants. at the 2021 and 2022 gec, intentional steps are being taken to create a more inclusive conference atmosphere for those from groups not well represented at the conference. these steps include a reconsideration of the gec experience to add a commitment to **\*\*diversity\*\*** and inclusivity to its reputation as a premier venue for gaseous electronics and plasma research. although demographic changes in research communities have slower time constants than might be desirable, the student participation enabled by this award has the potential for long term impact on the **\*\*diversity\*\*** of the future gec community. this approach includes introduction of several tested professional development and social events intended to appeal to early career attendees such as student research competition, including students from underrepresented groups. questions added to the post-conference survey will help to assess need for, interest in and effectiveness of the added events, and responses will be used to guide planning for subsequent future conferences. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Doctoral Dissertation Research in Economics: The Effects of Gender and Racial Stereotypes on Math Confidence, Effort, and Achievement

Awardee: National Bureau of Economic Research Inc

Amount: \$24,984.00

Abstract: this award is funded in whole or in part under the american rescue plan act of 2021 (public law 117-2). there are large, persistent gender and race gaps in stem participation and achievement, as well as persistent academic stereotypes about race and gender. this project seeks to understand the effects of providing information to elementary and middle school students to counteract the negative stereotypes and social norms surrounding the participation and achievement of under-represented groups in stem ? particularly the effects of this information on students? confidence, stem engagement, and achievement. while research show that stereotypes about ability matter for adults? confidence and participation in stem, these stereotypes emerge at much younger ages. this study will evaluate the impacts of intervening against these negative stereotypes early in students? educational trajectory, which may be more effective and more long-lasting than intervening with adults. in addition to increasing **\*\*diversity\*\*** in stem and encouraging more equal opportunities for all students, closing the gender and race gaps in stem engagement is expected to improve productivity and innovation in the sector and reduce wage gaps, since more than 90 percent of stem occupations offer wages above the national average. closing gaps in stem participation is thus a top priority for the us government as well as business leaders and professional organizations in stem fields. the results of this research could guide policies to close the racial and gender stem gaps and thus increase the supply of stem workforce. this will increase economic growth, decrease poverty as well as decrease income inequality in the us. this study will provide the first experimental evidence on the role of stereotypes in creating gaps in stem achievement. it will also provide novel evidence on the mechanisms through which stereotypes cause these effects; specifically, the effects of stereotypes on confidence, engagement with and responsiveness to feedback, and effort. this research uses a randomized intervention ? a series of

videos and exercises that provide information to counteract prevailing negative academic stereotypes ? delivered to students on a leading online learning platform to study these issues. student behavior on the platform will provide high-frequency measures of student effort, learning strategies, and engagement with feedback. additional outcomes will be measured in a survey, also integrated into the platform, which will provide psychometric and revealed-preference measures of math interest, confidence, and endorsement of stereotypes. finally, student achievement will be measured using standardized test scores. differences in outcomes between treated and control students will deliver the effect of the intervention, and the large set of considered outcomes will be used to test various mechanisms that explain the effect of race and gender stereotypes on math achievement. the results of this research could guide policies to close the racial and gender stem gaps and thus increase the supply of stem workforce. this will increase economic growth, decrease poverty as well as decrease income inequality in the us. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: NSF Postdoctoral Fellowship in Biology FY 2021: Does genomic recombination stabilize populations and enhance ecosystems?

Awardee: Nadeau, Christopher Paul

Amount: \$24,800.00

Abstract: this action funds an nsf postdoctoral research fellowship in biology for fy 2021, integrative research investigating the rules of life governing interactions between genomes, environment and phenotypes. the fellowship supports research and training of the fellow that will contribute to the area of rules of life in innovative ways. ecosystems provide invaluable services to humans such as maintaining water quality and reducing coastal flooding effects. a key rule of life is that ecosystems with more species often provide better and more consistent services. the same rule might also apply

within species, where populations with a higher **diversity** of individuals ? that is higher genetic **diversity** ? are more stable and provide better ecosystem services. if this is true, managing communities of species to maintain high genetic **diversity** could provide significant benefits to humans. however, within a single species, sexual reproduction alters genetic **diversity** over time by producing offspring with new combinations of genes (a result of recombination). this project asks whether this circumstance breaks down the aforementioned rule of life by disrupting optimal states of genetic **diversity**. by answering this question, new insights will be made about how to appropriately manage genetic **diversity** across geographic regions that encompass multiple levels of biological organization. the fellow will provide outreach activities associated with this work by involving members of underrepresented groups in research and training activities. this project will address how recombination at the intraspecific level alters predictions from interspecific theory, and therefore contributes to a cross-scale synthesis in biology. specifically, interspecific theory predicts that communities with a mix of highly diverged species will have higher stability and function. recombination at the intraspecific level could change this prediction because it can produce offspring with low fitness and thereby reduce stability and function (outbreeding-depression hypothesis). conversely, recombination between highly diverged genotypes could increase genotypic **diversity** among offspring and thus increase stability and function (increased-**diversity** hypothesis). the fellow will use genomics, lab-based breeding experiments, and field-based mesocosm experiments in a model system - daphnia magna - to test how divergence and recombination interact to alter population stability and function. the fellow will learn, apply, and advance genomic techniques for measuring the various forms of genetic divergence within species. the fellow will also produce a guide to genetic management for conservation practitioners, provide training and research exposure to two technicians from underrepresented communities in biology, and continue outreach to k-12 educators. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Workshop: Halo-DaSH: The Deep and Shallow History of Aquatic Life's Passages between Marine and Freshwater Habitats

Awardee: University of Connecticut

Amount: \$24,365.00

Abstract: this award supports a symposium and workshop, the goal of which is to highlight how biological exchanges between salty and freshwater habitats have transformed the biosphere. life in the ocean and in freshwater habitats have long been intertwined. major branches of the tree of life originated in the oceans and colonized fresh waters, often adapting to the new regime and diversifying. similar exchanges continue to this day, including some species that continually migrate between salty and fresh waters. scientists who study these processes typically focus on a single group of living organisms, or on the fossil record that documents ancient colonizations. the purpose of the activities supported by this grant is to stimulate new research on the history of life and

present-day stresses to aquatic systems. planned activities will consist of a day-long symposium during the 2022 annual meeting of the society for integrative and comparative biology, and a one-day workshop designed to facilitate innovative thinking and the involvement of scientists who are diverse in disciplinary orientation, country of origin, and stage of professional development. these interactions will yield products including manuscripts that synthesize research findings across disciplines and grant proposals for new research on gaps in knowledge that have been highlighted by the workshop collaborations. because global conditions such as sea level that shaped ancient exchanges are currently changing at a rapid rate due to intensifying human impacts, the results of the symposium and workshop should help scientists understand emerging threats to bio\*\*diversity\*\* related to changes in aquatic habitat solute concentration and global climate change. the symposium and workshop will address several questions about how biotic exchange between salty and fresh habitats has transformed the biosphere: when did major colonizations of fresh waters happen? what circumstances facilitated the transition? how frequent have been returns to marine habitats? how porous is the boundary: is change in halohabitat routine, requiring few modifications, or does it rarely occur because it requires special conditions and substantial genomic alterations? what adaptive changes occurred to accommodate the physiochemical and ecological differences? how do marine and freshwater lineages differ in organism-level features, ecological relationships, evolutionary processes? to what extent has diversification been propelled by the transitions? what differences in ecosystem services arise from these transformations? in what ways are the freshwater and marine forms subject to different anthropogenic stressors? the symposium, workshop, and resulting products will integrate findings at multiple levels of biological organization and from disparate fields, and use this science to better understand responses to global change in each realm. the transdisciplinary approach will allow participants to establish new collaborations and address questions that cross disciplinary boundaries, thereby stimulating new research to fill identified gaps in knowledge. diverse scientists from a broad range of disciplines, including graduate students and individuals from groups under-represented in science, will participate, and results will

be disseminated in journal articles, white papers, and via a project website, twitter account and instagram feed. the resulting collaborations will enhance interactions across biological and geoscience disciplines and will impact interdisciplinary curricula for undergraduate and graduate students. this award is co-funded by the physiological mechanisms and biomechanics program in the division of integrative organismal systems, directorate for biological sciences, and the sedimentary geology and paleobiology program in the division of earth sciences, directorate for geosciences. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: EAGER: Collaborative Research: Enhancing Asian American and Pacific Islander Participation and Belonging in the Geosciences

Awardee: Pennsylvania State Univ University Park

Amount: \$23,695.00

Abstract: asian americans and pacific islanders (aapi) represent one of the fastest growing demographics in the u.s. today and yet lag in participation and representation in geoscience graduate programs compared to other stem fields. thus, new programs are needed that specifically recruit aapi stem undergraduates to geoscience graduate programs and enhance belonging of aapi geoscientists as a whole. the proposed activities will focus on minority serving institutions (msis) that serve aapi. this project will expose as many as 1,000 undergraduates from msis in geoscience-adjacent stem fields to geoscience research and careers, provide a new research internship opportunity and create national cross-career stage connections between aapi geoscientists to produce a cohort of geoscience leaders from a group often left out of \*\*diversity\*\* discussions. aapi scientists desire to relate their work to local populations and problems relevant to their communities; therefore, diversifying geoscience graduate programs with those identifying as aapi will have a direct impact on communities facing important geoscience problems of the 21st century such as climate change, natural hazards, and resource scarcity. this project supports pilot programs to enhance participation and belonging for asian american and pacific islander (aapi) communities in geosciences. the proposed activities include: 1) establishing a researcher visit program to recruit undergraduate aapi into geosciences via visits to aapi-serving msis from

geoscience researchers; 2) a pilot research internship program for undergraduates at these institutions to carry out research with aapi mentors; 3) organizing virtual and in-person events and a career development workshop to enhance belonging, identity, and leadership within the aapi geoscience community across career stages and sectors. the outcomes of this combination of the proposed activities will help to develop geoscience programs, and create a cohort and community of belonging, access, justice, equity, **\*\*diversity\*\***, and inclusion (bajedi) leaders of aapi geoscientists. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: The Role of Marketplaces in the Development of Complex Society

Awardee: Humboldt State University Foundation

Amount: \$22,007.00

Abstract: this multidisciplinary pilot project identifies prehispanic marketplaces and establishes a set of marketplace indicators that can be applied elsewhere in the world. in the process, the project works with students to train a new generation of archaeologists currently underrepresented in the field. the objectives address a research gap that impedes archaeology's contributions to economic theory. pre-modern markets offer particular promise for adding **\*\*diversity\*\*** to economic ideas. isolated from global capitalist forces, these markets allow researchers to re-examine foundational concepts ? such as money, credit, debt, and investment ? in non-western contexts, expanding understanding of how culture influences economic behavior. for both theoretical and methodological reasons, however, archaeologists have only recently begun to establish the undisputed existence of pre-modern markets. previously prevailing western theories created a false dichotomy between past and present economies and suggested that market exchange ? the transfer of alienable goods and services between strangers ? could not exist outside of capitalism. while recent research has challenged these theories, archaeologists still lack sound methods for investigating the physical

manifestations of markets, market systems and marketplaces, which are often ephemeral, barely leaving a material imprint. few archaeological projects worldwide have even tried to identify marketplaces, and their locations remain an important missing component in pre-modern market research. to help fill this gap, eight independent research programs are cooperatively investigating a possible prehispanic regional market system by identifying marketplace locations. economic investigations in the region have lagged due to several factors, including a historical mischaracterization of the past society which had been conceived as less complex than those of other neighboring groups. researchers now however have begun to search for marketplaces as a sign of economic complexity. while marketplace investigations across archaeological sites have already had some success, varying metrics have hindered the research. additionally, the dense vegetation covering sites makes it difficult to employ conventional approaches such as examining item distributions, which rely on surface collections. to ensure comparable results, collaborators on this project are examining marketplace indicators by using a cross-cultural set of marketplace indicators that depend on a combination of approaches from archaeology, botany, soil science, and physics. researchers are analyzing both old and new data according to common protocols to produce joint results that address the central research hypothesis: an integrated system of large and small markets existed in the region, allowing access to similar goods for households within it. these results will further establish precedents for future research in terms of both methodology and cross-program cooperation. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: EAGER: Collaborative Research: Towards an Extensible Internet

Awardee: University of Washington

Amount: \$21,566.00

Abstract: the internet's basic design has remained largely unchanged since it first became commercial in the 1990s. now that the internet is the centerpiece of our global communications infrastructure, it is essentially impossible to alter its design in any significant way. unfortunately, such changes are needed to improve the internet's performance and security. this project aims to resolve this paradox with a design called the extensible internet. this is a collaborative project which brings together investigators from mount holyoke college, new york university, the university of washington, and international computer science institute at the university of california at berkeley. in today's internet, layer 3 has two basic functions: (i) connect all layer 2 networks and (ii) provide the packet delivery services on which host applications are built. the key aspect of the extensible internet is that it splits layer 3 into two layers. the first, which remains layer 3 and can use the current internet protocol (ip), handles the first function of connecting layer 2 networks. the second requires a new layer (called layer 3.5) that supports an extensible set of packet delivery services, and thus handles the second function of providing the services on which host applications are built. in this way, the extensible internet design leaves the current internet unchanged but is able to provide an extensible set of new packet delivery services that will improve the internet's performance and security. the extensible internet design is incrementally deployable (i.e., no unchanged applications or domains would lose connectivity), compatible with economic incentives, and can continue to evolve as new requirements arise. as such, it provides a practical way for the internet to evolve far beyond its current design. if the extensible internet design is adopted, it would have a significant impact on the nature of the internet. in particular, transitioning to the extensible internet is not just a one-time change in functionality, but transforms the internet from a single and unchanging service model (best-effort packet delivery) to an evolving and expanding set of network-provided services. in addition, in pursuing this agenda, the investigators will work to increase the **diversity** of the stem workforce through ongoing efforts in their own research groups and the outreach programs in their respective departments. the investigators will also incorporate their results into their courses and make the material freely available. all of the code from this project will be available on the

project's website at [extensibleinternet.org](http://extensibleinternet.org). this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: IRES Track II: Rivers of the Andes Field Training

Awardee: University of Colorado at Boulder

Amount: \$21,094.00

Abstract: this project will train students in interdisciplinary, international river sciences and prepare them for the stem workforce, for their research, and for applying river science toward developing sustainable solutions to the human-induced stresses on rivers in the andes and globally. the proposed 12-day advanced studies institute will immerse 14 us-based graduate students in innovative field training in hydrology, geomorphology, and ecology for, in each of two years. working in the magdalena river basin, colombia, students will learn cutting-edge field, remote sensing, and computational tools, develop critical and systems thinking, and complete team-based research projects. students will work with instructors from university of montana, university of colorado, and colombia, taking advantage of long-term research sites in the magdalena river basin and broad expertise. the rivers of the andes field training course will recruit a diverse group of students that broadens participation in sciences, and course materials and lessons learned will be shared openly and widely. river systems are under stress from climate change and growing demands for water, energy, and food. there is a strong disconnect, however, between where research and teaching about fluvial processes is concentrated, and where stresses on river systems such as new dam construction and associated impacts on humans and bio\*\*diversity\*\* are more recently evolving, such as in the andes. moreover, innovative and interdisciplinary approaches are needed to address challenges such as those surrounding river systems and to prepare students for the 21st century workforce. to address these challenges, we propose rivers of the andes field training (raft), a course

to be taught in colombia that will provide field-based training in river sciences. course content will focus on hydrology and fluvial geomorphology, especially river mechanics, floods, and sediment regimes, and complementary content in tropical fish ecology and basin-scale, cumulative-impact and decision-support analysis. raft will use the magdalena river and its tributaries as a field site to illustrate broader content about river processes and andean rivers. the course will augment field training with classroom teaching about fluvial processes and observational, measurement and modeling approaches for understanding river processes. raft will provide a transformative experience for graduate student participants by combining innovative approaches and technologies with evidence-based best practices to not only advance knowledge of river sciences and associated tools, but also to promote critical and systems thinking and observational, interdisciplinary, and teamwork skills. raft will include international and multicultural experience, interdisciplinary teaching on cutting-edge process knowledge and tools, training in cross-scale and systems thinking, team-based projects, and practice in science communication. participants will be equipped to tackle wicked problems at the nexus of water, energy, and food systems and to apply science toward sustainable solutions to the challenges surrounding rivers in the andes and in the anthropocene. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: 2021 NSF Student Poster Competition at the ASME International Mechanical Engineering Congress and Exposition (ASME-IMECE); Virtual; November 1-5, 2021

Awardee: University of Arkansas

Amount: \$19,900.00

Abstract: the objective of this researched effort is to provide support for 100 students who are currently working with principal investigators through nsf funding from the directorate for engineering (eng) or research experiences for undergraduates (reu) programs to attend the 2021 asme

international mechanical engineering congress and exposition (asme-imece) virtually and participate in a student poster competition. the awardees will be selected based on application including a brief resume, a one-page statement of why they want to attend the conference, and a statement of support from their faculty advisor. consideration in the selection process will be given to inclusion of members of underrepresented groups, **\*\*diversity\*\*** of institutions that the students represent, and **\*\*diversity\*\*** of programs within engineering. the competition is divided into the topics of (1) nsf-funded research grants/programs and (2) research experience for undergraduates (reus). this award will benefit the nation through the education of a skilled and diverse engineering workforce better prepared to provide transformative solutions the challenges of their chosen fields. this participation support is expected to benefit students' professional, scientific and technical development as they present their nsf funded research projects to the broad mechanical engineering community. attendance at the conference will provide the students a wonderful opportunity to learn about the engineering profession and state-of-the-art research in their fields via access to technical and professional development talks by domestic and international speakers. students will enhance their communication skills via lively discussions of their work with the top researchers in their fields during the society-wide poster symposium. they will also have an opportunity to attend many technical presentations, join the keynote and plenary sessions featuring technological pioneers, and network with potential mentors, colleagues, and employers. this interactive experience will significantly broaden their education, increase their enthusiasm for their research topic, acquaint them with expectations for scientific careers, and expose them to new avenues for innovative research. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Doctoral Dissertation Research: Articulatory Dynamics and Stability of Multi-gesture

## Complexes

Awardee: University of Southern California

Amount: \$18,962.00

Abstract: this award is funded in whole or in part under the american rescue plan act of 2021 (public law 117-2). spoken language production involves combined and coordinated articulatory actions of the tongue, lips, nasal port, and larynx; yet the natural variation in speech and the difficulty of "seeing" events occurring inside the human vocal tract mean that the elegant choreography of these articulatory events critical to the formation of spoken words remains mysterious. this project is a study of speech production using real-time magnetic resonance imaging (rtmri)?a technique that can image vocal tract movement during speech. the project's goal is to characterize the dynamics of articulatory actions as they are organized into coordinated complexes such as speech segments (roughly ?alphabetic-sized? units). the investigation of stabilities in coordination will help scientists understand the cognitive representation of the linguistic units that are used to structure and say the words we know. ultimately such an understanding has implications for language in breakdown (e.g., due to stroke or disease), for language acquisition, for language and dialect **\*\*diversity\*\***, and for technologies that synthesize and recognize human speech. this dissertation undertakes real-time mri experiments on speech production and concomitant computational modeling to examine how the smallest movement 'atoms' of speech segments are systematically coordinated. the project tests the hypothesis that vocal tract movements composing a segmental unit are tightly coordinated with one another. therefore, their coordination is predicted to be stable across natural contextual variations in speech such as phrase boundaries and emphasis, unlike other movement sequences spanning across segments, which have been shown to exhibit more plastic coordination. using data from two under-studied languages, both larynx-oral coordination in glottalic consonants and velum-oral coordination in nasal consonants are dynamically imaged, and vocal tract movements are tracked to analyze articulatory patterning and coordination in space and time. empirical findings are computationally assessed using a model of dynamical coupling with which degrees of stability can

emerge from certain coupling structures. the project seeks to incorporate coordination relations into linguistic cognitive representations and thereby illuminate the dynamic and emergent nature of speech segments in the encoding system of the phonological units that form words. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: The Role of Marketplaces in the Development of Complex Society

Awardee: Elon University

Amount: \$18,648.00

Abstract: this multidisciplinary pilot project identifies prehispanic marketplaces and establishes a set of marketplace indicators that can be applied elsewhere in the world. in the process, the project works with students to train a new generation of archaeologists currently underrepresented in the field. the objectives address a research gap that impedes archaeology's contributions to economic theory. pre-modern markets offer particular promise for adding **\*\*diversity\*\*** to economic ideas. isolated from global capitalist forces, these markets allow researchers to re-examine foundational concepts ? such as money, credit, debt, and investment ? in non-western contexts, expanding understanding of how culture influences economic behavior. for both theoretical and methodological

reasons, however, archaeologists have only recently begun to establish the undisputed existence of pre-modern markets. previously prevailing western theories created a false dichotomy between past and present economies and suggested that market exchange ? the transfer of alienable goods and services between strangers ? could not exist outside of capitalism. while recent research has challenged these theories, archaeologists still lack sound methods for investigating the physical manifestations of markets, market systems and marketplaces, which are often ephemeral, barely leaving a material imprint. few archaeological projects worldwide have even tried to identify marketplaces, and their locations remain an important missing component in pre-modern market research. to help fill this gap, eight independent research programs are cooperatively investigating a possible prehispanic regional market system by identifying marketplace locations. economic investigations in the region have lagged due to several factors, including a historical mischaracterization of the past society which had been conceived as less complex than those of other neighboring groups. researchers now however have begun to search for marketplaces as a sign of economic complexity. while marketplace investigations across archaeological sites have already had some success, varying metrics have hindered the research. additionally, the dense vegetation covering sites makes it difficult to employ conventional approaches such as examining item distributions, which rely on surface collections. to ensure comparable results, collaborators on this project are examining marketplace indicators by using a cross-cultural set of marketplace indicators that depend on a combination of approaches from archaeology, botany, soil science, and physics. researchers are analyzing both old and new data according to common protocols to produce joint results that address the central research hypothesis: an integrated system of large and small markets existed in the region, allowing access to similar goods for households within it. these results will further establish precedents for future research in terms of both methodology and cross-program cooperation. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Doctoral Dissertation Research: Subjacency, the Empty Category Principle (ECP), and the nature of constraints on phrase movement

Awardee: University of Maryland, College Park

Amount: \$18,539.00

Abstract: this award is funded in whole or in part under the american rescue plan act of 2021 (public law 117-2). in general, it is possible to form a question by 'moving' a wh-phrase like "who?" or "which boy" out of a seemingly arbitrary number of clauses, as in "who did allie say that amy saw?", "who did alicia hear that allie said that amy saw?", and so on. in these questions, "who" is the logical object of "saw" yet appears at the beginning of the sentence. however, there are certain syntactic environments, commonly called 'islands,' in which question formation is not possible. a question like "who did the book by delight everyone?"--whose intended meaning is 'who is the person such that the book by that person delighted everyone'--sounds unnatural to speakers of english, suggesting that it is not a possible question despite having a reasonable meaning. some linguists have claimed that these constraints disappear when the offending structure is elided, such as in a sentence like "amy said that the book by someone delighted everyone, but i don't remember who". such sentences sound a bit more natural to speakers of english, but their status isn't entirely clear. this dissertation project will advance linguistic theory by using recent experimental techniques to ascertain whether such sentences are grammatical. in advancing the field, this project will also support education and **\*\*diversity\*\*** by training an undergraduate research assistant in these experimental techniques, scientific thinking, and statistical analysis. using behavioral methods, this doctoral dissertation project probes the link between speakers' reported judgments and their sensitivity to structure in questions with and without ellipsis. the goal is to determine whether the same principles apply to dependencies involving ellipsis as those that do not, with the longer term goal of identifying the computational principles governing syntactic locality. more generally, the

project addresses the consequences of mismatches between reported acceptability and subliminal sensitivity to structure in acceptability judgments. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Varieties of Crises, Elite Responses, and Executive Approval

Awardee: University of Connecticut

Amount: \$16,739.00

Abstract: this award is funded in whole or in part under the american rescue plan act of 2021 (public law 117-2. this project examines four major types of crises -- economic, security, natural disaster, and public health crises ? and how they influence public support for political leaders in contemporary democracies. this is important to understand because leader approval is a key barometer of policymaker accountability and democratic stability, both of which can be undermined by crises. this project analyzes the interplay of four factors which vary systematically across these different types of crises and how, in turn, these shape public evaluations of political executives: (1) the ability of citizens to assign responsibility for policy decisions and outcomes; (2) the degree of expert consensus on effective policy response; (3) how much a given crisis in one area generates acute challenges or crises in other areas; and (4) the extent to which an effective response depends on citizens acting collectively. several data sets including (quarterly) measures of executive approval and crises; the tone and salience of leader messaging about the crises; the media's treatment of leader messaging; and (monthly) leader approval for a smaller number of countries for which such data is available; and survey-based experiments in three countries are collected and made publicly available. the award supports education and **\*\*diversity\*\*** by building the research capacity of a student project lab at georgia state university, a minority serving institution, in coordination with pis at four other universities who will also engage graduate and undergraduate students in this work.

puzzling divergences across countries in public reactions to leader responses to the covid-19 public health crisis have revealed major gaps in our understanding of how crisis events translate into public assessments of leaders. to resolve these puzzles, this project advances a unifying theoretical framework that identifies four major types of crises: economic, security, natural disaster, and public health. it then locates these crises on four key dimensions which should condition public support of top officials: the institutional and political context and other factors that impact attribution of responsibility, degree of expert consensus and incentives for politicians to follow expert recommendations, the likelihood and nature of spill-over to other crisis types, and the degree to which citizen action is required for an effective response. the project collects data to test theoretically-motivated hypotheses using: 1) a macro time-series cross-national data set to study the effects of crisis type on public approval for political executives for 48 countries, 2) a high-frequency time-series data set appropriate to test how approval dynamics reflect leader responses, as well as messaging choices and media effects for 18 countries for which this data is available, and 3) conjoint experiments in france, italy, and mexico, countries with different political and institutional settings, to assess the validity of the links between crisis types and dimensions as well as to validate proposed individual-level mechanisms. this project is supported by the accountable institutions and behavior program and the sbe build and broaden program. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Doctoral Dissertation Research: The effects of nutritional ecology and feeding competition on growth and development

Awardee: George Washington University

Amount: \$15,750.00

Abstract: this award is funded in whole or in part under the american rescue plan act of 2021 (public law 117-2). learning what to eat, how, and where to find food are significant challenges that arise over the course of development. such challenges can also be social, when individuals have to compete with others for access to food. yet how feeding competition affects food choice and developmental outcomes is poorly understood, particularly in scenarios where food is abundant and distributed evenly across an environment. this doctoral dissertation research tests how variation in feeding ecologies, including food competition, affects food choice and developmental outcomes among wild juvenile non-human primates inhabiting changing ecological and demographic environments. results contribute to existing conservation management plans and provide concrete training opportunities to graduate and undergraduate students. results will be disseminated widely to academic and non-academic audiences. the proposal merges theory from nutritional ecology and life history to investigate the significance of feeding competition among developing non-human

primates, who lack the foraging competence of adults. major objectives include investigating: 1) variation in food nutritional properties along ecological gradients; 2) development of adult-like foraging competence; and 3) impacts of feeding competition on dietary development of infant and juvenile individuals. the researchers integrate novel and long-term data on food nutritional properties and feeding behavior sampled across a **\*\*diversity\*\*** of habitat types. they collect novel nutritional data from plant food samples as well as feeding data generated through long-term monitoring and new behavioral observations. results inform understanding of the evolution of primate juvenile periods, by improving our understanding of how immatures are impacted by feeding competition, even in contexts where food is apparently abundant. further, this research generates insights regarding developmental responses to changes in ecology, which are important for predicting population dynamics and associated implications for conservation efforts. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: EAGER: Collaborative Research: Enhancing Asian American and Pacific Islander Participation and Belonging in the Geosciences

Awardee: Princeton University

Amount: \$15,599.00

Abstract: asian americans and pacific islanders (aapi) represent one of the fastest growing demographics in the u.s. today and yet lag in participation and representation in geoscience graduate programs compared to other stem fields. thus, new programs are needed that specifically recruit aapi stem undergraduates to geoscience graduate programs and enhance belonging of aapi geoscientists as a whole. the proposed activities will focus on minority serving institutions (msis) that serve aapi. this project will expose as many as 1,000 undergraduates from msis in geoscience-adjacent stem fields to geoscience research and careers, provide a new research

internship opportunity and create national cross-career stage connections between aapi geoscientists to produce a cohort of geoscience leaders from a group often left out of \*\*diversity\*\* discussions. aapi scientists desire to relate their work to local populations and problems relevant to their communities; therefore, diversifying geoscience graduate programs with those identifying as aapi will have a direct impact on communities facing important geoscience problems of the 21st century such as climate change, natural hazards, and resource scarcity. this project supports pilot programs to enhance participation and belonging for asian american and pacific islander (aapi) communities in geosciences. the proposed activities include: 1) establishing a researcher visit program to recruit undergraduate aapi into geosciences via visits to aapi-serving msis from geoscience researchers; 2) a pilot research internship program for undergraduates at these institutions to carry out research with aapi mentors; 3) organizing virtual and in-person events and a career development workshop to enhance belonging, identity, and leadership within the aapi geoscience community across career stages and sectors. the outcomes of this combination of the proposed activities will help to develop geoscience programs, and create a cohort and community of belonging, access, justice, equity, \*\*diversity\*\*, and inclusion (bajedi) leaders of aapi geoscientists. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: 2021 EDGE Summer Symposium

Awardee: Pomona College

Amount: \$14,993.00

Abstract: the 2021 edge (enhancing \*\*diversity\*\* in graduate education) summer symposium is a three-day event that addresses mathematical research and professional development. the symposium uses a vertical mentorship model to fill in a variety of gaps (academic and non-academic) that are not guaranteed to be filled by other means. the community built during edge

programs is the primary mechanism that increases retention, access to professional opportunities, and likelihood that our participants don't just succeed, they thrive and are propelled into careers in the mathematical sciences that influence the whole community. the edge summer symposium combines research talks, panel discussions, and formal and informal networking events. the edge symposium will bring together (virtually and in-person) 75 mathematicians, primarily an intersection of women and graduate students, and will be hosted by the university of minnesota in minneapolis. participants of the summer symposium discuss cutting-edge research, motivating further discoveries and empowering less senior participants to strive for similar work. these more junior participants also receive indispensable career advice, while more established mathematicians hone their mentoring skills, strengthen their own support network, and deepen their commitment to influencing the next generation of mathematicians. in increasing the number of women who succeed in graduate school and beyond, the summer symposium increases the visibility of a diverse collective of mathematicians, inspiring younger mathematicians to persevere and become leaders in the mathematical sciences. further information about the edge program may be found at: <https://www.edgeforwomen.org/> this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: EAGER: Using allies to expand your network: Implementing a psychological methodology to attract and retain underrepresented (UR) students in geoscience

Awardee: Texas Tech University

Amount: \$14,715.00

Abstract: geoscience maintains a base-rate problem with respect to **diversity**: ethnic minorities and people with disabilities are highly underrepresented. this has been traced to a variety of barriers for underrepresented (ur) ethnic scholars including: a lack of geoscience majors at hbcus and

primarily hispanic-serving institutions, a lack of experience with, and time spent in, nature (e.g., < 3% of visitors to u.s. national parks are black and hispanic), and negative attitudes about career prospects. for people with disabilities, the main challenge is accessibility and the provision of appropriate accommodations. ur individuals may self-select out of geoscience programs due to these perceptions and barriers. this project will test the idea that allies, or members of dominant social identities, are best situated to positively influence these statistics. academic allies, whether faculty or graduate student teaching assistants, have tremendous impact on their students? academic engagement and can serve as linchpins for improving the future trajectories of ur students. pis will train individuals in effective allyship behaviors, and incentivize them to recruit ur students into their academic field trips. the pis plan to target allies who engage in field research and education, as geoscience is a unique stem field insofar as much of the data collection and skill development are practiced out in nature at locations around the world. the pis propose testing a strategy to overcome barriers in this context for ur students, as positive (or negative) experiences in field settings have profound impacts on recruitment and retention. this project will facilitate training and assessment of approximately 80 academic allies and measure the effect of that training on allies as well as hundreds of majority and ur students. the expectation is that the training will produce a secondary effect: academic allies role model effective behaviors to all of their students and faculty networks, creating a ?train-the-trainer? ripple effect. the pis will use academic field trips as a vehicle for measurement, including multisource ratings, applying 360-degree-type ratings typically collected in performance appraisals to this setting. deliverables include an experimental, longitudinal (over time), and multisource analysis of the allyship program and its improvement of allyship-related attitudes and behaviors, as well as its impact on the performance of ur students. these results will inform research efforts regarding the effectiveness of implemented strategies, and the materials and procedure will be made open-source for maximum replicability. a capstone conference will be used to disseminate findings to all participating allies and ur students, inform about methodologies that improve attraction and retention of ur groups in the geosciences, and

expand ur networks. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Using Herbivorous Insect Genomes for Crop Tracking

Awardee: Washington University

Amount: \$14,175.00

Abstract: the goal of this project is to conduct a research study of the histories of crop range expansions by indigenous north americans. the domestication and assisted dispersal of plant and animal species by humans has dramatically changed global ecosystems, but the direct study of historical domestication of some species is often limited by methodological challenges. for example, while the ancestral ranges and subsequent range extensions of some north american crops are well studied, others remain relatively inaccessible. this research explores whether historical signals of range expansion captured within the genomes of insects, parasitic on focal crop plants, can be used as proxies for the histories of the plants themselves. this research provides a general proof of principle for using parasitic insects to study demographic histories of their plant hosts, but also specifically tests hypotheses for the pre-domestication ranges and histories of expansion for three crops of the eastern agricultural complex (eac): common sunflower, jerusalem artichoke, and sumpweed. this research results in the training of graduate and undergraduate students, lead to design and implementation of new materials for public outreach demonstrations, and bring about a large public science event focused on the indigenous agriculture. this research uses information captured in the genomes of specialist insects to reconstruct signatures of past cultivation and subsequent range expansions for three north american crops; the work addresses the questions: where did these plants grow before they were first used as crops, and where (and when) were they subsequently moved by people? common sunflower, jerusalem artichoke, and sumpweed are

known to have been cultivated by indigenous north americans as part of the eastern agricultural complex, but beyond this there is great variance in how much is known about their respective ancestral ranges and subsequent patterns of range extensions. two fly species in the north american genus *Stratiotia* feed on, respectively, common sunflower and jerusalem artichoke, while caterpillars of the slender flower moth are specialist herbivores on sumpweed. the researchers are making large collections of these three insect parasites from across their host plants' ranges in the north america, and then interrogating their genomes for signals of historical population size changes and the direction and timing of range expansions. a general prediction is that the region of highest genetic **\*\*diversity\*\*** for each insect will correspond to the historical boundaries of the eac, implicating this area as having been part of the ancestral range for each plant. a second expectation is that tests of demographic scenarios using genetic data will best support relatively recent range expansions, radiating out from their respective native range(s). this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: ABI Development: Improved Tools for Population Genomics

Awardee: San Diego State University Foundation

Amount: \$13,444.00

Abstract: the goal of this project is to develop computer software that allows scientists to compare the genomes of natural populations of organisms. population genomics (the study of **\*\*diversity\*\*** in the genomic dna of populations instead of individuals) has important applications in agriculture, anthropology, conservation, medicine, and several other fields of biology. recent technology advances have greatly lowered the cost of dna sequencing so large amounts of data are available. at the same time statisticians have developed new methods for analyzing large collections of genome-sized data. combining the data with the new analysis approaches can let scientists answer

fundamental questions about the biology of species that have never before been accessible. however, most population genomics studies fail to take advantage of the latest population genomics statistical methods. this is because the genomic data requires a lot of processing to prepare it for the analysis steps, and these operations are not easy to learn. lack of bioinformatics knowledge has led to erroneous conclusions, irreproducible results, incomplete analyses, and slow turnaround time of population genomics projects. this project aims to provide software that can handle those tasks in a consistent and correct way and allow direct access to the statistical tools, to bring about new insights in population biology. this project will address the largest impediments to model-based population genomics by building a user-friendly and intuitive pipeline platform, the "pop-gen pipeline platform" (ppp). this platform will help researchers avoid the problems inherent in re-inventing data processing scripts to feed data into their population genomics analyses, and considerably reduce time and effort. ppp will include tested scripts and pipelines for data preparation, and in addition the tools needed to build evolutionary models, carry out analyses of data, and create visualization of results via the ruffus computation pipeline library in python. ppp will also be developed as a stand-alone application with a graphical user interface (gui) under the popular and robust galaxy project ([www.galaxyproject.org](http://www.galaxyproject.org)) for bioinformatics analyses. an online server deploying galaxy/ppp will be developed and maintained at temple university, philadelphia ([www.dev3.cst.temple.edu](http://www.dev3.cst.temple.edu)) for users to interactively submit jobs on a first-come-first-served basis. online forums will be established for support, and to collect suggestions regarding what is desired for further development under ppp. tutorials and videos about example applications of the ppp will be added to the galaxy project wikipedia training channels. additionally, a significant part of this work will involve educating temple university seniors, philadelphia area high school teachers, and their students about the power of bioinformatics in modern biology through summer workshops. information about ppp, and associated developments can be accessed at <https://bio.cst.temple.edu/~hey/software/software.htm>.

Title: ABI Development: Improved Tools for Population Genomics

Awardee: San Diego State University Foundation

Amount: \$13,444.00

Abstract: the goal of this project is to develop computer software that allows scientists to compare the genomes of natural populations of organisms. population genomics (the study of **diversity** in the genomic dna of populations instead of individuals) has important applications in agriculture, anthropology, conservation, medicine, and several other fields of biology. recent technology advances have greatly lowered the cost of dna sequencing so large amounts of data are available. at the same time statisticians have developed new methods for analyzing large collections of genome-sized data. combining the data with the new analysis approaches can let scientists answer fundamental questions about the biology of species that have never before been accessible. however, most population genomics studies fail to take advantage of the latest population genomics statistical methods. this is because the genomic data requires a lot of processing to prepare it for the analysis steps, and these operations are not easy to learn. lack of bioinformatics knowledge has led to erroneous conclusions, irreproducible results, incomplete analyses, and slow turnaround time of population genomics projects. this project aims to provide software that can handle those tasks in a consistent and correct way and allow direct access to the statistical tools, to bring about new insights in population biology. this project will address the largest impediments to model-based population genomics by building a user-friendly and intuitive pipeline platform, the "pop-gen pipeline platform" (ppp). this platform will help researchers avoid the problems inherent in re-inventing data processing scripts to feed data into their population genomics analyses, and considerably reduce time and effort. ppp will include tested scripts and pipelines for data preparation, and in addition the tools needed to build evolutionary models, carry out analyses of data, and create visualization of results via the ruffus computation pipeline library in python. ppp will also be developed as a stand-alone application with a graphical user interface (gui) under the popular and robust galaxy project ([www.galaxyproject.org](http://www.galaxyproject.org)) for bioinformatics analyses. an online server deploying galaxy/ppp

will be developed and maintained at temple university, philadelphia ([www.dev3.cst.temple.edu](http://www.dev3.cst.temple.edu)) for users to interactively submit jobs on a first-come-first-served basis. online forums will be established for support, and to collect suggestions regarding what is desired for further development under ppp. tutorials and videos about example applications of the ppp will be added to the galaxy project wikipedia training channels. additionally, a significant part of this work will involve educating temple university seniors, philadelphia area high school teachers, and their students about the power of bioinformatics in modern biology through summer workshops. information about ppp, and associated developments can be accessed at <https://bio.cst.temple.edu/~hey/software/software.htm>.

Title: EAGER: Collaborative Research: Enhancing Asian American and Pacific Islander Participation and Belonging in the Geosciences

Awardee: University of Hawaii

Amount: \$12,763.00

Abstract: asian americans and pacific islanders (aapi) represent one of the fastest growing demographics in the u.s. today and yet lag in participation and representation in geoscience graduate programs compared to other stem fields. thus, new programs are needed that specifically recruit aapi stem undergraduates to geoscience graduate programs and enhance belonging of aapi geoscientists as a whole. the proposed activities will focus on minority serving institutions (msis) that serve aapi. this project will expose as many as 1,000 undergraduates from msis in geoscience-adjacent stem fields to geoscience research and careers, provide a new research internship opportunity and create national cross-career stage connections between aapi geoscientists to produce a cohort of geoscience leaders from a group often left out of **\*\*diversity\*\*** discussions. aapi scientists desire to relate their work to local populations and problems relevant to their communities; therefore, diversifying geoscience graduate programs with those identifying as aapi will have a direct impact on communities facing important geoscience problems of the 21st

century such as climate change, natural hazards, and resource scarcity. this project supports pilot programs to enhance participation and belonging for asian american and pacific islander (aapi) communities in geosciences. the proposed activities include: 1) establishing a researcher visit program to recruit undergraduate aapi into geosciences via visits to aapi-serving msis from geoscience researchers; 2) a pilot research internship program for undergraduates at these institutions to carry out research with aapi mentors; 3) organizing virtual and in-person events and a career development workshop to enhance belonging, identity, and leadership within the aapi geoscience community across career stages and sectors. the outcomes of this combination of the proposed activities will help to develop geoscience programs, and create a cohort and community of belonging, access, justice, equity, **\*\*diversity\*\***, and inclusion (bajedi) leaders of aapi geoscientists. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: The Rising Stars in Cell Biology Symposium

Awardee: Johns Hopkins University

Amount: \$10,892.00

Abstract: this award provides support for a one-day meeting ?the rising stars in cell biology symposium? to be held on april 29, 2022 at johns hopkins university. the purpose of the meeting is to provide an opportunity to early career scientists (undergraduate, post baccalaureate, graduate students, and postdoctoral fellows) from diverse backgrounds within the greater baltimore area to present their research and network with their peers. the format of the meeting will comprise of one

keynote talk, selected oral presentations, poster sessions, and career development platforms. in the short-term, this meeting will provide an opportunity to trainees to highlight their exceptional research, boost their confidence, expose them to a wide array of leading-edge research within cell biology, which may lead to increased recruitment of under-represented minority (urm) students into graduate programs or postdoctoral positions across the participating institutions. in the long-term, this meeting will attract urm scholars to science, technology, engineering and mathematics (stem), specifically to life sciences and to generate a vibrant and supportive environment that encourages retention of urm scientists in academia. this meeting is motivated by the recognition of socio-economic disparity and the need for opportunities truly available to urm scholars. the award will defray the basic organizing expenses to reach a wide group of trainees as well as institutions that predominantly serve urm scholars in the greater baltimore area. in particular, the award will provide support for the meeting participants in the form of travel vouchers, working meals, poster printing, and childcare assistance. availability of opportunities provided by the meeting will showcase the trainees' work and form a peer network, which will encourage urm scholars to continue their academic pursuit and help increase **diversity** at higher ranks within academia. additionally, with the participants from diverse backgrounds but sharing the common interest in cell biology, this meeting is expected to foster scientific collaborations at the forefront topics and advance research forward. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Proposal GEOPATHs:IN Recruiting through location-based Curriculum and Field and Laboratory Research Experience for High School Students, Teachers and Undergraduates

Awardee: Nevada System of Higher Education, Desert Research Institute

Amount: \$9,770.00

Abstract: this award is funded in whole or in part under the american rescue plan act of 2021 (public law 117-2). improvements to stem k-12 education and increasing the number and **\*\*diversity\*\*** of young people headed into stem careers have been identified as national priorities. this project seeks to address aspects of both of these priorities in the context of geoscience education and workforce **\*\*diversity\*\***. the project will encourage high school students including many from historically excluded groups, to become involved in the geosciences or other stem disciplines by 1) engaging them in lesson plans developed by participating teachers to explain the local landscape and natural environment in which they live, 2) offering them opportunities to participate in geoscience research projects at the university of nevada, las vegas and 3) by building personal connections between students and faculty at unlv. to facilitate interactions with high school students pis will build long term relationships with high school earth science teachers by hosting summer workshops in which teachers will be provided with information about the local geology and natural environment and assist them in creating lesson plans for their classrooms. the activities will build up to a culminating experience where the teachers and high school students have an opportunity to claim their own identity as budding geoscientists. this project will encourage high school students including

many from historically excluded groups to become involved in the geosciences or other stem disciplines. the program will strengthen the relationship between the university of nevada (unlv) and the local community, including the local school district. project objectives will be accomplished through a comprehensive program that will include: 1) building a professional earth science learning community to facilitate collaboration between local high school teachers and unlv faculty/students; 2) generating high school earth science curriculum materials based on the local geologic resources that will provide stem education opportunities while also introducing potential career paths in the earth sciences; 3) creating a service learning course that will pair undergraduate "geoscience ambassadors" with high school classes that are utilizing the newly developed curriculum materials; and 4) engaging highly motivated high school students, high school teachers, and unlv undergraduate students in high profile, locally relevant scientific research questions in a way that leverages cutting edge analytical equipment in the unlv geoscience department. the workshop curriculum content and materials will be designed in consultation with curriculum experts so that they mesh well with the teachers' needs and address concepts outlined in the nevada academic content standards for science. resultant outcomes will bear benefits to teacher and student participants, faculty and the community as the project demonstrates how to build the geoscience workforce at the local level. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Online Workshop on Synchrotron X-Ray Needs for Soft Matter Far From Equilibrium; June/July 2021

Awardee: Cornell University

Amount: \$9,071.00

Abstract: This grant will support a highly interdisciplinary on-line workshop identifying important fundamental questions related to soft matter far from equilibrium and how to employ x-ray tools to answer these questions. Much of the richness of the world around us ? and in fact life itself ? arises from conditions and processes far from equilibrium. And yet in contrast to systems at or near-equilibrium, our understanding of the basic principles of far-from-equilibrium systems is in its infancy. Non-equilibrium processes are particularly relevant in soft-matter systems, with huge impacts on areas ranging from health to energy to manufacturing. X-ray scattering studies, particularly using synchrotron radiation, are uniquely able to probe the three-dimensional, atomic-scale structure of soft matter over a wide range of time- and spatial scales, providing critical information needed to elucidate the fundamental processes and later to control them. Non-equilibrium processes are particularly relevant in soft-matter systems. Since their structures are based on weak interaction forces, including dipolar, hydrogen bonding, pi-pi, or screened electrostatic interactions, even small external perturbations can substantially alter the behavior of

soft matter. in macromolecular systems, for example, structural relaxation times can be very long. as a result, they often retain a memory of the preparation or processing conditions, a key to the large **\*\*diversity\*\*** of macromolecular structures and many technological innovations. furthermore, in analogy to biology, the study of soft dissipative systems with an ability to produce energy and convert it from one form to another has led to the emergent field of active matter. in recent years, efforts have intensified to study non-equilibrium processes in soft matter systematically in order to explore the entirely novel phenomena associated with transient structure, order, and dynamics, and to improve our fundamental understanding of them. synchrotron-based x-ray radiation has emerged as a particularly useful tool to contribute to this understanding. this workshop will: 1. identify important science questions related to "soft matter far from equilibrium" during advanced manufacturing processes such as roll-to-roll printing of highly structured materials; 2. determine how these questions can be addressed using synchrotron-based x-ray capabilities; 3. identify critical needs for and characteristics of synchrotron-based x-ray resources to support this research; and 4. identify the broader impacts of providing such resources to the soft matter community. the outcomes of the workshop will be captured in a workshop report to be submitted for publication. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Proposal for a SUMMIT to Plan a Conference Workshop for Minoritized Geoscientists

Awardee: University of Washington

Amount: \$8,784.00

Abstract: this project aims to host a four-day summit with fifteen leaders from geoscience organizations with a demonstrated interest in improving belonging, accessibility, justice, equity, **\*\*diversity\*\***, and inclusivity (beajedi). the summit will provide these leaders with opportunities to

share successful strategies for improving beajedi in geoscience. leaders at the summit will design a conference where ~100-300 geoscientists network, present their research, and share successful strategies for improving beajedi in geoscience. the summit will thus begin the process of increasing interagency and interpersonal sharing, design, and refinement of the strategies used to strengthen beajedi in geoscience. the main goal of this project is to host a four-day summit with 15 leaders from the largest and or influential geoscience organizations with a demonstrated interest in improving belonging, accessibility, justice, equity, **\*\*diversity\*\***, and inclusivity (beajedi) in geoscience. summit participants will collaboratively design a conference workshop while sharing successful strategies for improving beajedi for geoscientists of color. this designed workshop will be primarily attended by geoscientists and will allow attendees to present research and network. the workshop will also include surveying and interviewing attendees to collect information that are germane for successfully recruiting and retaining people of color within geoscience. the questions that the surveys and interviews seek to answer are: 1. what attracts people of color to geoscience? 2. what are the experiences of geoscientists of color? 3. what do full belonging, accessibility, justice, equity, **\*\*diversity\*\***, and inclusivity look like to geoscientists of color? alongside developing a novel method of answering the questions listed above, this project's broader impacts are strengthened by including a mentorship component. the summit will pair early-career researchers interested in beajedi issues with established and experienced individuals. the early-career researchers will gain conference proposal writing experience while expanding their network. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Doctoral Dissertation Research in Economics: An experimental analysis of the role of group identity in leadership effectiveness

Awardee: George Mason University

Amount: \$8,327.00

Abstract: this award is funded in whole or in part under the american rescue plan act of 2021 (public law 117-2). understanding the role of leaders in mitigating cooperation failures in groups especially when group members have distorted incentives is a relevant issue in economics. this research project will use economic theory and experimental methods to study whether beliefs and decisions of group members vary according to whether the leader shares the same group identity as the followers. the project will combine insights from behavioral economics, social psychology, leadership, and management studies to compare the effectiveness of ingroup and outgroup leaders. social identity theory suggests that a shared group identity between leaders and followers could increase trust in an ingroup leader's effectiveness in fostering cooperation. the research design will investigate whether ingroup bias can lower overall cooperation and efficiency in groups with outgroup leaders. ingroup bias can become a challenge for effective diverse leadership. this research will help to fill in gaps in knowledge of the detrimental effects of ingroup bias and will have broad impacts on the study of leadership. further, the results of this research project will shed light on identity-based discrimination which can provide important inputs into policies that improve **\*\*diversity\*\*** and inclusion in leadership. in a novel laboratory experimental design, the project uses identity manipulations within a leadership game. groups play a public goods game where the leader encourages cooperation within each group following a two-fold identification strategy which

creates artificial group identities. laboratory subjects acting as followers decide whether to follow a leader's cooperation suggestion in a group task. the main hypothesis is that the ingroups will exhibit favoritism towards ingroup leaders and discrimination against outgroup leaders. the difference in a group's cooperation levels under ingroup and outgroup leadership will help in isolating the effects of shared group identity on leadership effectiveness. extending this to a second study where the leaders use a reward mechanism to incentivize higher cooperation it can be observed whether a reward mechanism can bridge the gap between ingroup and outgroup leader effectiveness. the project makes two contributions. it provides an interdisciplinary approach to studying the interaction effects of group identity and leader effectiveness. second, the results will allow researchers to understand the ramifications of shared social identities between leaders and followers and prevent the negative consequences that may arise out of the lack of inclusion of diverse leaders. overall, the results will have policy implications for both organizations and policy makers. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Amount: \$1,657.00

Abstract: this workshop will bring together antarctic marine freshwater and terrestrial biologists, students, and experts in specimen curation to assess the value of, need for, and scope of a

biological repository of antarctic specimens, including tissue samples. currently, some us collected antarctic specimen collections are housed in various museums, repositories, and labs. these collections are not easily discoverable on the internet, and how well they represent the bio\*\*diversity\*\* of antarctica is largely unknown. the workshop coordinators will advertise the conference broadly and recruit underrepresented groups to participate. participants will assess current repositories and determine how to make antarctica biological samples more accessible in a unified location (or through better coordination). this effort will benefit the broader community of biologists working with antarctic organisms by providing opportunities to conduct antarctic science by investigators and their students that might otherwise not be possible due to the logistical and budget challenges for deployments. following workshop activities, a final report will be published on the outcomes of the efforts. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: A Workshop for Evaluating the Value and Scope of a Biological Repository of Antarctic Specimens

Awardee: Ohio University

Amount: \$1,657.00

Abstract: this workshop will bring together antarctic marine freshwater and terrestrial biologists, students, and experts in specimen curation to assess the value of, need for, and scope of a biological repository of antarctic specimens, including tissue samples. currently, some us collected antarctic specimen collections are housed in various museums, repositories, and labs. these collections are not easily discoverable on the internet, and how well they represent the bio\*\*diversity\*\* of antarctica is largely unknown. the workshop coordinators will advertise the conference broadly and recruit underrepresented groups to participate. participants will assess

current repositories and determine how to make antarctica biological samples more accessible in a unified location (or through better coordination). this effort will benefit the broader community of biologists working with antarctic organisms by providing opportunities to conduct antarctic science by investigators and their students that might otherwise not be possible due to the logistical and budget challenges for deployments. following workshop activities, a final report will be published on the outcomes of the efforts. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: CAREER: Precipitation Pathways and Deformation Micromechanisms of Refractory Superalloys (RSAs)

Awardee: University of Miami

Amount: \$0.00

Abstract: this award is funded in whole or in part under the american rescue plan act of 2021 (public law 117-2). part 1: non-technical summary the disruptive potential of a superior class of high-temperature structural materials is immense, and would revolutionize the energy sector and aerospace industry while advancing our military technologies. for example, such materials would enable stationary gas turbines (which produce 40% of all u.s. electricity) and aerospace gas turbines (which account for 5% of man-made global warming) to operate at higher temperatures. higher engine temperatures provide greater engine efficiency and boost power output from powerplants and aviation, contributing to a stronger economy while reducing greenhouse gas emissions and enabling tactical superiority for military aircraft. the recent discovery of refractory high entropy superalloys (rsas) that possess excellent combinations of high strength and ductility at room-temperature and elevated temperature is extremely promising, especially as normal refractory alloys are typically brittle under ambient conditions. the proposed research identifies

knowledge-gaps regarding deformation mechanisms, microstructure stability at high temperatures and addresses these gaps through advanced materials characterization, mechanical testing and simulation, including national laboratory facilities. such analysis and understanding are critical for accelerated materials development to realize next-generation powerplants and aerospace engines. this project not only meets demands for advanced materials but synergistically reduces talent gaps in science and engineering. the university of miami college of engineering is collaborating with the phillip and patricia frost museum of science, which receives approximately 700,000 visitors annually. the collaboration serves to increase awareness and interest in metallurgy, and its impact on lowering co2 and energy footprints of air travel and electricity production, through integration of ongoing research and education initiatives.

part 2: technical summary    the project goal is to study the precipitation, strengthening and deformation mechanisms of refractory high entropy superalloys (rsa) by specifically testing the hypotheses that (i) the precipitation formed on quenching is due to spinodal decomposition, which raises concerns regarding long-term stability of the two-phase microstructure, and that (ii) the excellent mechanical properties are due to co-deformation of both phases via activation of the  $a\langle 111 \rangle$  slip system, given the preferred  $a\langle 001 \rangle\{001\}$  mechanism does not satisfy the criterion for polycrystalline ductility. the application of in-situ small-angle x-ray and neutron scattering to determine the time dependent fourier transform of the composition variation, and thereby directly test for spinodal decomposition, while simultaneously monitoring for phase transformations in a wide-angle detector, significantly contributes to the understanding of precipitation pathways in alloys. in-situ neutron diffraction during elastic loading provides fundamental data (such as phase stiffnesses) necessary for phase field simulations regarding microstructure evolution. in-situ diffraction during plastic deformation combined with tem dislocation analysis probes the deformation micromechanics and reveals why rsas exhibit a combination of strength and ductility, whereas refractory (single-phase) alloys are typically brittle at ambient temperature. the fundamental research regarding phase evolution, spinodal decomposition and slip systems within body-centered cubic alloys is significant across multiple alloy systems, essential for

the development of rsas, and necessary to advance high-temperature metallurgy. the stem talent gap is addressed through a tight integration of research and education. the development of an undergraduate course that offers an educational opportunity to perform research alongside faculty and industry engineers enhances materials education in south florida. the lack of **\*\*diversity\*\*** in stem is addressed through a multi-step program, where u. miami is ideally located in a majority-minority city and educates a highly diverse student body. significant awareness and understanding in metallurgy is generated through partnership with the frost science museum, where statistical surveys monitor success of these education and outreach activities. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Travel: Math Circles Around the World Conference

Awardee: Kansas State University

Amount: \$0.00

Abstract: this nsf award supports the travel of u.s. based mathematicians to the international conference "math circles around the world" scheduled to take place in st. petersburg, russia, july 1?3, 2022, as a satellite to the international congress of mathematicians. the conference is dedicated to mathematics enrichment programs and research experiences for school students. over the next decades these programs will have a major impact on the future development of stem disciplines in the united states. early engagement of school students in advanced math activities is today?s investment in the future of science and technology. participation of the us delegation will inspire more active engagement of professional mathematicians into math outreach programs and help advocate recruitment and retention of diverse populations to math programs for school students. in the long run this experience will have a very positive impact on the scientific community in the united states. conference participants will review existing practices of dissemination of

mathematics, advertise the achievements of math circle programs in the usa, develop deeper understanding of the context of mathematical culture in different countries, establish new international collaborations, and acquire practical skills that include recruitment and retention of more diverse population into stem education. the project seeks to broaden the **\*\*diversity\*\*** of participation of the meeting and to increase international visibility of the us-based leaders of math circles. mathematicians at an early stage of their careers and underrepresented groups will especially benefit from the travel support for this conference. more information about the conference is found at the website: <https://www.mathcirclesworld.org> this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: CAREER: Peatland Geomorphology: Quantifying Geomorphological Changes across SE Asia  
Peatlands

Awardee: University of Oregon Eugene

Amount: \$0.00

Abstract: this project will determine how a process resulting from human activities (peat degradation due to deforestation) influences natural hazards (flooding) and climate change (carbon dioxide emissions). peatlands are wetlands where waterlogged conditions slow plant decomposition to such an extent that dead plants accumulate to form peat. under natural conditions peat domes grow over time, storing carbon underground and minimizing the risk of coastal flooding. in contrast, damaged peatlands are compacting, which results in a lowering of the ground elevation and in greenhouse gas emissions. this project proposes to integrate multiple satellite- and ground-based datasets with artificial intelligence tools to address a question of high societal importance: ?at what rates will thousands of years of accumulated peat carbon be released to the atmosphere and on what timescale will large coastal areas in southeast asia become permanently flooded?? retrospectively,

in louisiana, it was shown that the impact of hurricane katrina would have been less severe without the preceding decades of peat degradation. this project will proactively quantify when and where flooding will become the most severe in southeast asia and improve our understanding of peatland dynamics worldwide. knowledge from this work will enable forecasting future peat decomposition rates and flooding hazards, and refine estimations of carbon dioxide fluxes. these results will inform outreach efforts aimed to empower local communities through education, boost engagement of scientists in public communication, and increase undergraduate **\*\*diversity\*\*** through early exposure to hands on research. the goals of this project are to establish the capability to predict the fate of tropical peatlands and their carbon in response to environmental changes and to develop effective ways to engage the population on the importance of peatlands. the central hypothesis of this project is that peat degradation rates are controlled by the landscape morphology and land use history. to test it, this project will rely on three main tasks: 1) identify the controls on peat degradation rates across southeast asia by combining morphology (light detection and ranging data), deformation (interferometric synthetic aperture radar data validated by fieldwork), and land use timeseries (multi-spectral optical data); 2) develop a machine learning model accounting for the controls on degradation rates to predict the timing and amplitude of future degradation, carbon dioxide emissions, and the associated flooding; and 3) increase awareness on the importance of peatlands by sharing socially responsive outreach material. the developed techniques will provide a critical framework for worldwide peatland geomorphology studies. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Doctoral Dissertation Research in Economics: Residential Segregation and Neighbor-Based Informal Hiring

Awardee: Columbia University

Amount: \$0.00

Abstract: this award is funded in whole or in part under the american rescue plan act of 2021 (public law 117-2). place-based job policies, such as informal neighborhood job search, are common tools to promote local job growth and reduce regional economic inequality. it is however not clear what makes a neighborhood good for job search. this research project will study one such mechanism---the use of neighbor networks in job search. it explores which type of neighborhood---segregated or integrated, by race and by education---is more conducive to a successful job search. disentangling the neighborhood effects on job search is difficult partly because people self-select into neighborhoods. the researchers use a policy experiment on refugee that were randomly assigned to neighborhoods throughout the country to overcome the self-selection problem. the project can help shed light on how local social connections can be harnessed for effective resettlement and faster integration of these special immigrants into the labor market at the destination. second, in answering this question, this research project will be a step towards understanding the relationship between neighborhood **\*\*diversity\*\*** and prosperity. the results of this research can provide guidance on improving the functioning of labor markets, especially for those in segregated neighborhoods. the results could therefore help guide policies to reduce unemployment in low income segregated neighborhoods. identifying neighborhood effects in general is challenging because of residential sorting. different individuals may choose to live in different places for reasons unobservable to the econometrician. to overcome this selection issue and obtain causality, the project will exploit a refugee settlement program that randomly dispersed refugees across the country, conditional on a set of demographic characteristics and housing availability. this natural experiment introduces conditionally exogenous variation in the demographic composition at the neighborhood level for new and incumbent residents. the project will complement this natural experiment with granular geographical data that accommodate the resizing/redefining of neighborhoods. this flexibility and the policy-induced variation will allow causal estimation of the impacts of neighborhood segregation on the use of neighbor networks in job

search. in so doing, the research will help bridge two areas of economic literature ? neighborhood effects and networks-based informal hiring ? that heretofore have developed largely in isolation from each other. the results of this research will provide guidance on improving the functioning of labor markets, especially for those in segregated neighborhoods. the results could therefore help guide policies to reduce unemployment in low income segregated neighborhoods. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Use-Inspired Climate Change Solutions: A TOS-ASLO Workshop Series

Awardee: Oceanography Society

Amount: \$0.00

Abstract: the oceanography society (tos) and the associated sciences for limnology and oceanography (aslo), the two largest professional societies of aquatic scientists in the us will hold a

series of community-driven information collecting events to identify interdisciplinary and convergent challenges the nation and world are facing due to climate change. a focus will be to crowdsource research directions and solutions to mitigate the threats posed by climate change in such a way that major impacts to society and the economy will be realized within a quick time frame. outreach to the limnology and oceanographic communities will be spearheaded by a task force of thought leaders with a membership reflecting diverse interdisciplinary expertise, gender **\*\*diversity\*\***, career stage, and ethnicity. activities will be professionally facilitated and will be tied to identifying solutions that target sustainability science. results of the community outreach will include a synthesis of workshop/communication venue results as well as the mining of information from recent professional society abstracts to augment the in-person/virtual conversations and input. broader impacts of the work will be to surface transformational, global ideas that accelerate use-inspired, entrepreneurial, and nature-based solutions to the threats the nation and world are facing due to a warming world which is driving climate change. as such, the potential societal impacts are great. other impacts include aquatic science community building; support of the development of early-career scientists; enhancing interdisciplinary, inter-agency, and international collaborations; and providing vehicles for connections between government, academic, and the private sector that link scientists in developed and developing nations in accelerating the design and implementation of use-inspired climate change solutions.

climate change and its impacts on the environment, society, patterns of land use, locations of communities, etc. are serious problems facing the nation and the world. the two us premier professional societies of aquatic scientists (the oceanographic society and the associated sciences of limnology and oceanography) will use their network of thousands of scientists to obtain input and crowdsource ideas for solutions to tractable issues being caused by climate change. these professional societies will jointly hold meetings, surveys, and conversations with members, nationally and internationally, to identify possible areas in which convergent science that crosses disciplines and stakeholder groups and where major advances in a short time frame can be made. the two professional societies will generate a report that will be submitted to the national science

foundation.    this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.
