Total Funding: \$1,604,375,625.00

Number of Awards: 1275

Title: Graduate Research Fellowship Program (GRFP)

Awardee: Stanford University

Amount: \$76,809,648.00

Abstract: the national science foundation (nsf) graduate research fellowship program (grfp) is a highly competitive, federal fellowship program. grfp helps ensure the vitality and **diversity** of the scientific and engineering workforce of the united states. the program recognizes and supports outstanding graduate students who are pursuing research-based master's and doctoral degrees in science, technology, engineering, and mathematics (stem) and in stem education. the grfp provides three years of financial support for the graduate education of individuals who have demonstrated their potential for significant research achievements in stem and stem education. this award supports the nsf graduate fellows pursuing graduate education at this grfp institution. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: SII-Center: SpectrumX ? An NSF Spectrum Innovation Center

Awardee: University of Notre Dame

Amount: \$24,174,664.00

Abstract: the worldwide growth of wireless communication, navigation, and telemetry has provided immense societal benefits including mobile broadband data, internet of things, mobile healthcare, and intelligent transportation systems. this award is a grant to establish a spectrum innovation initiative: national center for wireless spectrum research (sii-center) to ensure united states

leadership in future wireless technologies, systems, and applications in science and engineering through the efficient use and sharing of the radio spectrum. an sii-center will promote transformative use and management of the electromagnetic spectrum, charting a trajectory to ensure united states leadership in future wireless technologies, systems, and applications in science and engineering through the efficient use and sharing of the radio spectrum. an sii-center will also educate and develop an agile workforce needed to support industries of the future which rely heavily on wireless technologies. this award funds the establishment of the first national center for wireless spectrum research, spectrumx. the vision for spectrumx is to be an inclusive multidisciplinary and increasingly interdisciplinary center that applies convergence research and team science to promote coexistence among disparate use cases in the radio spectrum, particularly including ?public good? use cases for science and defense. in particular, spectrumx will pursue its initial research strategy in scientific receiver hardware with interference measurement and mitigation capabilities; instrumentation of the radio spectrum in terms of advanced sensing networks; collecting and sharing accurate regulatory, usage, and economic data; flexible use rights that align incentives with efficient outcomes; and distributed, data-rich, and cloud-ready system designs for more efficient spectrum management and utilization. the project team is led by the university of notre dame, bringing together broad and synergistic research capabilities from a team of 41 founding researchers and staff from 27 universities, including 14 minority-serving or majority non-white institutions, and partnerships across industry, government, and academia. the center will be an information and innovation hub connecting stakeholders. spectrumx has a broadening participation plan aimed to increase awareness of cultural competence for all center participants to ensure that **\*\*diversity\*\***, equity, and inclusion are woven into the core of the center?s values and culture. spectrumx will develop spectrum-related curriculum for grade 6 through master?s students and has an education and workforce development plan to offer flexible pathways for researchers and students from diverse backgrounds, disciplines, and levels of maturity to engage in spectrum innovation. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the

foundation's intellectual merit and broader impacts review criteria.

Title: STC: Center for Research On Programmable Plant Systems

Awardee: Cornell University

Amount: \$19,750,000.00

Abstract: this nsf science and technology center aims to devise a two-way communication system between humans and plants that will dramatically enhance the ability to predict, design, and mediate biological behavior in crop-based agriculture. this transdisciplinary effort brings together plant sciences, engineering, computer science, and science and technology studies to establish an

enabling framework for the systematic discovery of the rules that govern biological behavior of plant systems in field environments. the team's approach couples genetic, biochemical, cellular, organismal and ecological principles with environmental and socio-economic considerations. in parallel, the center's research drives innovation in systems and synthetic biology, biotechnology, nanotechnology, automation, robotics, computing, and communication. the center educates students through new curriculum and research engagements that integrate computer science, engineering, and public engagement with knowledge in biology and the life sciences for undergraduate, master's, and ph.d. students. the center integrates public engagement throughout all activities to drive continuous, iterative dialogue between the center's researchers, stakeholders in the agricultural sector, and the general public. the center strives to engage the full **\*\*diversity\*\*** of our society and broaden participation in its mission by creating pipelines into stem fields and sustained mentoring for students and young professionals from rural and underrepresented minority communities.

in pursuit of its scientific and technological goals and its aim for broader impacts, the center organizes research across an innovation engine with four technological thrusts and a discovery engine with four research themes called living laboratories. these interlinked teams engage in continuous cycles of design-build-test-learn across disciplines, technical challenges, and scientific and social goals. the innovation engine focuses on building and integrating the elements of an internet-of-living-things (iolt) through the following thrusts: (1) biotransducers give rise to programmable plants through synthetic biological gene circuits that enable bidirectional communications between molecular processes in plants and digital sensors. (2) nanotransducers improve and complement molecular biological transducers to enable communication between plants and digital systems. (3) digital interfaces develop agile and cooperative robots, communications technologies, and edge-computing capabilities to mediate efficient communication between programmable plants and cloud-hosted models. (4) digital systems develop integrated multi-scale models of plant systems that integrate data and orchestrate actuation across the iolt with hybrid mechanistic and data-driven strategies. furthermore, the living laboratories of the discovery engine

interact with all thrusts in pursuit of the following research themes: (1) resource use and growth optimization deploy programmable plants to dissect the pathways that define water and nitrogen use and plant development, and modulate these processes for improved outcomes in productivity and sustainability. (2) predictive modeling and germplasm improvement use the iolt, programmable plants, and integrative multi-scale models to predict emergent phenotypes in complex environments and accelerate the process of breeding crops with improved performance. (3) plant-microbe interactions apply technologies from the innovation engine to access the physical, chemical, and microbial dynamics of the near-root zone or rhizosphere and integrate plant-microbiome characteristics into systems biology models, breeding strategies, and crop management. (4) public engagement permeates all center activities to facilitate and study productive interactions among researchers, stakeholders, and general publics around the development, understanding, and communication of scientific and technological goals. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Mid-scale RI-1 (M1:IP): A Deep Soil Ecotron facility to explore belowground communities and ecosystem processes

Awardee: Regents of the University of Idaho

Amount: \$18,950,956.00

Abstract: an award is made to the university of idaho to implement a deep soil ecotron facility that will lead to an improved understanding of deep soils, further illuminating the variety of life on the planet, its role in ecosystem processes, and its response to global change. the deep soil ecotron will provide research infrastructure that the us currently lacks, accelerate research on deep soils and the role these soils play in the broader biosphere, and lead to the development of novel technologies aimed at assessing belowground structure and function. additionally, the deep soil ecotron will serve as the central hub for a network of epscor researchers focused on questions related to deep soils. this national network currently has representatives from nine epscor jurisdictions. graduate students will be involved in all aspects of the deep soil ecotron. these students, recruited from

underrepresented groups, will receive unprecedented training in project management. the project management program, which will include workshops, classes, and hands-on-experience, will generate the future leaders and innovators of infrastructure development in the environmental sciences. finally, the groundwork for future generations of soil researchers will be laid by expanding an established middle school curriculum development program, where middle school students will design and conduct mini-ecotron experiments. the understanding gained from this facility can help mitigate the degradation of the nation's soil resources and help address future challenges, thus ensuring soil bio\*\*diversity\*\*, food security, and climate mitigation capacities for future generations.

not unlike the deep ocean, little is known about deep soils. currently, research on deep soils is limited to excavating soil pits, which limits research and experiments that directly manipulate the deep soil environment are currently non-existent. the deep soil ecotron will give researchers the unparalleled ability to investigate deep soils. this facility, composed of twenty-four, highly instrumented ecounits, will allow for soil profiles up to three meters in depth to be repeatedly sampled and continuously monitored. the deep soil ecotron will enable researchers to address the following four broad research needs using approaches and instrumentation which have been unattainable under more common field and laboratory experiments. first, the deep soil ecotron will reveal how deep soil communities and processes affect and interact with surface soils to influence whole ecosystems. second, the deep soil ecotron will allow researchers to determine how deep soils respond to global and land-use change, such as increasing soil temperature and agricultural management practices. third, information gained from the deep soil ecotron will be integrated into earth system models to improve model representation. fourth, the deep soil ecotron will provide a testbed for the development of sensors for the in-situ monitoring of deep soils. ultimately the deep soil ecotron will be the first of its kind in the world, shedding light on a largely unknown and unexplored environment, and accelerating research on belowground systems. this project is jointly funded by the mid-scale ri-1 program, the established program to stimulate competitive research (epscor), and infrastructure innovation for biological research (iibr) program. this award reflects

nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: NSF ZEUS Multi-Petawatt Laser Facility: Operations

Awardee: Regents of the University of Michigan - Ann Arbor

Amount: \$16,500,000.00

Abstract: the g rard mourou center for ultrafast optical science at the university of michigan will operate a new laser user facility to be called nsf zettawatt-equivalent ultrashort pulse laser system (zeus) facility. the nsf zeus facility will operate the most powerful laser in the us and will provide unique and world-leading capabilities for scientific research. the nsf zeus facility will have an open and transparent review process for facility access with at least 30 weeks per year dedicated to external user experiments. the facility will have local and national economic and societal impact through training of students and post-doctoral researchers at universities throughout the us, with specific outreach efforts focused on increasing demographic **\*\*diversity\*\*** of the zeus user community. the facility will also foster innovation in the field of laser technology, potentially enabling formation of new high tech companies. the new nsf zeus user facility will include a multi-beam 3 petawatt (pw) laser system that will have three radiation-shielded experimental target areas to accommodate differing experimental configurations for users. the zeus laser system will have three modes of operation, either for experiments using a single 3 pw beamline, dual beam 2.5 pw/500

terawatt (tw) or up to 300 tw at higher repetition rate. a nanosecond-duration 75 j shock driver beamline for generating high-energy-density states of matter will also be available. the repetition rate of zeus at full power will be one shot per minute but will also have a higher repetition rate mode at 5 hz for powers up to 300 tw. this additional operational mode will enable a significant amount of data to be taken, which is particularly important for x-ray (up to 50 kev) and neutron (up to 20 mev) imaging applications. these bursts of x-rays and neutrons produced by zeus will have ultra-short pulse duration and can also be used for probing dynamic events at picosecond or femtosecond temporal resolution. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: iDigBio: Sustaining the digitization, mobilization, accessibility, and use of biodiversity specimen data in U.S. museum and academic collections

Awardee: University of Florida

Amount: \$15,917,274.00

Abstract: integrated digitized biocollections (idigbio.org) at the university of florida (uf), florida state university (fsu), and arizona state university (asu) is the national coordinating body for the sustained effort to digitize, and make available online, the vast amount of information in the nation's bio\*\*diversity\*\* collections, which may contain up to 1 billion specimens. for biological specimens, information digitized include names of species, localities and dates of collection, digital photographs, sound, video, and 3-d models created from a variety of sources. this community digitization effort was catalyzed by nsf's advancing digitization of bio\*\*diversity\*\* collections (adbc) program via thematic collections networks (tcns), groups of institutions that digitize specimens to address a

major research topic such as the relationship between agricultural crops and insects or the impacts of invasive species on natural ecosystems. idigbio assists in coordinating activities of the tcns by facilitating development of standards and workflows for digitization of specimens and related information, providing cyberinfrastructure resources to enable long-term preservation of digital data, promoting novel and traditional uses of collections data in research and outreach, and working with the collections community to plan for the long-term sustainability of the national effort and the resources it has produced. the availability of digitized information about specimens greatly enhances the ability to conduct research on biological **diversity** and to address some of the most fundamental questions in biology. over the past ten years, the national effort to digitize information in the nation's bio**diversity** collections has been significantly advanced by the activities of idigbio. collaborations with data providers and users have been developed, goals and priorities defined, best practices related to digitization identified, and global collaborations with bio**diversity** data aggregators established. cyberinfrastructure resources, including a national search portal, have been provided. these community-driven activities have led to improved digitization practices, increased involvement in digitization and training, and adoption of instruments and informatics tools that improve the efficiency and scalability of digitization and research workflows in all types of bio**diversity** collections. idigbio works with staff in more than 926 collections in 317 institutions distributed across all 50 states. communication among stakeholders to increase access to collections data has been established through workshops, webinars, and the use of social media. since 2011, idigbio has sponsored attendance of 16,768 participants from 1,034 institutions to 430 workshops, webinars, symposia, and events that targeted digitization-related topics. idigbio has ingested 1,651 record sets containing 128 million specimen records and 41 million media records. all data ingested are indexed to enable queries and other types of index-based access. searches for data can be done through a web-based graphical interface or through programmatic apis. search and analytical tools enable users to mine diverse data such as taxonomy, location, images, traits, and vocalizations. during this award period, idigbio to continue its successful strategies with an

increasing emphasis on data improvement and use in research and outreach and to incorporate such rapidly developing technologies as artificial intelligence and machine learning in bio\*\*diversity\*\* data integration. idigbio is recognized as an essential resource for information on bio\*\*diversity\*\* and digitization. as the scientific and societal benefits of validated collections data are realized, digitization will become a common and sustained practice in natural history collections. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: AI Institute for Engaged Learning

Awardee: North Carolina State University

Amount: \$15,678,072.00

Abstract: emerging breakthroughs in ai create significant and timely opportunities for accelerating innovation relevant to pressing national challenges in stem education. advances in ai are enabling new levels of interactivity, engagement, and inclusion. driven by a vision in which ai supports and extends the intelligence of teachers and learners, the nsf ai institute for engaged learning will design, develop, and investigate ai-driven narrative learning environments that create engaging story-based, collaborative problem-solving experiences. the institute will conduct foundational ai research in natural language processing, computer vision, and machine learning, as well as in ai ethics. building on these foundational advances, the institute will conduct use-inspired ai research on narrative learning environments with rich ai-driven virtual agents and powerful multimodal sensing capabilities to understand how students learn and collaborate in rich story-based problem scenarios. the institute will provide a robust infrastructure to support at-scale implementations of ai-driven narrative learning environments. it will create a nexus for distinctive innovations in in-school and out-of-school stem education. its research vision will be to empower diverse learners to become the next-generation stem workforce by creating generative, collaborative ai-driven

narrative learning environments that deeply engage learners in schools, at museums, and within their own communities. this vision will be informed by connections with diverse stakeholders to ensure that the institute's learning environments are ethically designed and promote **\*\*diversity\*\***, equity, and inclusion. the nsf ai institute for engaged learning will produce transformative advances in stem teaching and learning by bringing together a team of diverse researchers from four universities (north carolina state university; indiana university, university of north carolina at chapel hill; vanderbilt university), as well as an educational non-profit organization (digital promise) which will bring educational practitioners, policy makers, and product developers into the work. the institute's partners include a national network of k-12 schools, museums, and non-profit organizations. the institute will create narrative learning environments that generate interactive stories dynamically tailored to the needs and interests of individual students and small groups and in multiple settings (classrooms, after-school programs, and museums). the institute's research has three complementary thrusts, to create: (1) narrative learning environments that generate engaging interactive story-based problem scenarios that elicit rich communication, require coordination, and spark collaborative creativity; (2) embodied conversational agent technologies with multiple modalities for communication (speech, facial expression, gesture, gaze, and posture) to support engaging learning interactions. embodied conversational agents will be driven by advances in natural language understanding, natural language generation, and computer vision; and, (3) an innovative multimodal learning analytics framework that analyzes parallel streams of multimodal data derived from students' conversations, gaze, facial expressions, gesture, and posture as they interact with each other, with teachers, and with embodied conversational agents. woven throughout the institute's activities will be a strong focus on ethics, with an emphasis on creating ai-augmented learning that is deeply informed by considerations of fairness, accountability, transparency, trust, and privacy. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: I-Corps Hub: Mid-Atlantic Region

Awardee: University of Maryland, College Park

Amount: \$12,725,124.00

Abstract: the broader impact/commercial potential of this i-corps hubs project is to catalyze an inclusive mid-atlantic innovation network to spur the development of deep technology startups that will have much-needed economic and societal impacts regionally, nationally, and globally. research universities are positioned to support commercialization of scientific discoveries, and nsf i-corps accelerates the growth and impact of university-launched deep technology ventures. the uniquely-experienced mid-atlantic region i-corps hub team will build on the initial success of i-corps nodes to continue the cultural transformation at several of the country's top research universities to embed innovative practices into the conceptualization and conduct of research; to solve critical societal problems; and to create jobs, opportunities, and economic value. this hub project directly aligns with the goals of the american innovation and competitiveness act, which is critically important

for previously industrialized regions such as the mid-atlantic region as it is experiencing significant economic turmoil due to shifts in american manufacturing industries, compounded by disruptions due to the pandemic. also, the hub vision and strategy prioritizes **diversity**, equity, and inclusion, particularly among underrepresented groups and underserved minorities and minority institutions like historically black colleges and universities (hbcus). the i-corps program curriculum is built on scientific methods that incorporate hypothesis testing, the build-measure-learn cycle, and continuous iteration. multiple outcomes result from the program, teams: change research directions, get funding from grants or private investors, or form start-up companies and grow through revenue. equally important, the impact of the program accrues over many years. the hub model enables alignment of a systematic and comprehensive analysis of regional impacts, as well as the programmatic, environmental, and individual factors that mediate the efficacy of the program itself. understanding for whom and under what conditions i-corps programs are most effective, and what factors contribute to or detract from this effectiveness is critical to inform the continued growth and scaling of i-corps. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: NSF I-Corps Hub: West Region

Awardee: University of Southern California

Amount: \$12,550,000.00

Abstract: the broader impact of this i-corps hubs project is the development of a model technology innovation hub in the western united states that cultivates the creation of deep technology ventures and builds a robust innovation ecosystem that is diverse, inclusive, and representative of its population. this goal will be achieved through education, training, outreach, and the engagement of a diverse community of innovators, with robust linkages to regional and national entrepreneurial

ecosystems, leading to a strong commercial impact. trainers and trained teams are key hub outputs. proactive outreach is expected to result in the recruitment of diverse groups of teams, trainees, mentors, and instructors. in addition, i-corps training may help increase the flow and impact of commercializable technologies, the growth and **\*\*diversity\*\*** of the innovation ecosystem, and the supply of mentors and experts for the training of future teams. the hub plans to engage in research and education in lean startup-based programming, the financing of innovation, and the broader ethics of technology innovation and entrepreneurship. through education, training, networking, community building, and research outcomes related to deep technology ventures, the hub seeks to deliver economic, technology, and social impact for the benefit of the region and the nation. this i-corps hubs project is based on the development of a comprehensive and inclusive education and training program for innovation and entrepreneurship in deep technology ventures in the western united states. the hub will engage deep technology researchers in lean-startup and customer discovery methodologies to produce teams that advance to the national i-corps program further enhancing the national innovation network. the project will use a framework for team generation and training pipelines based on best practices developed by the hub members, further modified to leverage the hub regional characteristics, in particular, its distinct, diverse demographic signature. the hub plans to incorporate inclusivity in its standardized and integrated approach as well as ethical considerations in team training. the hub will also explore new approaches that may lead to a creative, enabling, human-centric, and socially-relevant innovation ecosystem in the region. in parallel, research is planned to analyze programs for possible additional refinements in hub practices as well as to enrich the broader scholarship and public policy on innovation and entrepreneurship, including a better understanding of innovation financing. specifically, the project will assess differences in programming and funding success for underrepresented groups and the career paths of scientists and engineers in the general entrepreneurial ecosystem. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: NSF I-Corps Hub: Northeast Region

Awardee: Princeton University

Amount: \$12,550,000.00

Abstract: the broader impact of this i-corps hubs project is the development of a regional network of academic, industrial and government partnerships that will grow the nation's capacity to transform scientific discoveries into tangible societal benefits. the hub, located in the heart of the northeast region of the u.s., will leverage its proximity to deep technology industries including pharmaceuticals, nanotechnology, chemistry, energy, and photonics. serving as a catalyst to democratize access to opportunities through educational and training programs, the hub will translate laboratory discoveries generated at the principal, partner, and affiliate institutions to spur formation of new commercial ventures, leveraging the significant volume of federal research dollars already invested in this region. built on robust industrial and government partnerships, the hub has a proven track record of successful collaborations and entrepreneurial activities including previous nsf i-corps sites and industry-funded research collaborations. through a demonstrated commitment to inclusivity and

**\*\*diversity\*\***, the hub will contribute to america?s future prosperity and global competitiveness by training the next generation of innovators from diverse backgrounds. ultimately, the hub will contribute to the growth of america?s technology-driven economy by accelerating the translation of academic discoveries into the marketplace. this i-corps hub project is based on the development of a northeast regional network that will educate, guide, mentor, and support innovators across all participating institutions, and promote the translation of fundamental scientific and engineering discoveries into tangible products through the creation of new commercial ventures. this vision will be realized by leveraging the training techniques from the i-corps program to create a comprehensive ecosystem that supports innovators through the entire ideation and technology venture lifecycle. training and mentoring will focus on empowering academic researchers via i-corps programming geared towards developing critical thinking around deep-tech commercialization, customer discovery, and impact creation. additional programming, specifically geared toward faculty members, will seek to create lasting impact by continuing to leverage academic discoveries to benefit society through entrepreneurial ventures. this approach emphasizes the holistic programming necessary for long-cycle, deep-tech startups and the sharing of best practices from different institutions, enabling synergistic learnings and motivation. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: BII: Uncovering mechanisms of amphibian resilience to global change from molecules to landscapes

Awardee: University of Pittsburgh

Amount: \$10,338,698.00

Abstract: paramount to predicting the future of bio**\*\*diversity\*\*** is knowing when and how living systems are resilient to (i.e., can recover from) anthropogenic disturbances. the focus of this biology

integration institute is on understanding resilience to a key global threat: emerging infectious diseases. the team will develop a new framework to measure resilience across multiple scales, stressors, and systems, and apply it to a case study involving a fungal disease linked to global amphibian declines. building on past research in four complementary systems, the team will address four questions: (1) how does the history of disturbance differ across systems? (2) how have changes at different levels of biological organization shaped overall system responses? (3) what are the mechanisms contributing to resilience and are they shared across systems? (4) how is resilience modulated by multiple interacting stressors? the framework and findings will be applicable to hundreds of amphibian species facing disease-related stressors and, more broadly, for understanding the resilience of biological systems to myriad global change threats. the institute's training activities will reach and connect high school through postdoctoral scholars using authentic biology research experiences that foster cross-disciplinary understanding, serve large numbers of students with a focus on underrepresented groups, and promote persistence in stem. outreach activities will reach students, teachers, members of the public, and wildlife managers with messages about bio\*\*diversity\*\*, resilience, and global change. together, the institute's activities will showcase the power of an integrative, team science approach for addressing some of the biggest and most challenging questions in biology.

the focus of this biology integration institute (bii) is on understanding resilience in the context of global change. resilience, or the ability to recover after a perturbation, is an emergent property of living systems. progress toward a mechanistic understanding has been stymied by the lack of a common currency and framework that is applicable across scales, among systems, and in response to different stressors. the team's activities will address these knowledge gaps by developing a flexible resilience framework and applying it to a detailed case study involving a key global change threat to bio\*\*diversity\*\*: emerging infectious diseases (eids). leveraging past research, the team aims to uncover mechanisms of resilience to chytridiomycosis, an eid of amphibians caused by a fungal pathogen, in four complementary systems by answering four key questions: (1) how does the history of disturbance differ across

systems? (2) how have changes at different levels of biological organization shaped overall system responses? (3) what are the mechanisms contributing to resilience and are they shared across systems? (4) how is resilience modulated by multiple interacting stressors? the institute's training and outreach programs will feed back into the research. training activities will reach and connect high school through postdoctoral scholars from across the country through authentic biology research experiences that foster cross-disciplinary understanding, serve large numbers of students with a focus on underrepresented groups, and promote persistence in stem. outreach activities will reach students and teachers, members of the public, and wildlife managers with messages about global change and resilience. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Center for Advanced Radio Sciences and Engineering

Awardee: University of Puerto Rico Mayaguez

Amount: \$9,437,465.00

Abstract: the center for advanced radio sciences and engineering established in this award will enable the development of integrated tools to resolve spectrum sharing and coexistence issues, and improve performance on radio science observations through an innovation and collaboration ecosystem designed to elevate the science and engineering capacity at university of puerto rico at mayagüez (uprm), arecibo observatory (ao), and puerto rico in general. the center will explore new concepts in radio astronomy, atmospheric sciences, spectrum monitoring and radio frequency interference mitigation, with a focus on scientific observations. the center will improve the research competitiveness of the puerto rico engineering and academic communities, training a new generation of students via hands-on experience with leading-edge research infrastructure and internships. the creation of this center will foster new collaborations between ao, the national radio astronomy observatory (nrao), industry, and the puerto rico academic community, which will both enrich radio sciences and engineering and position puerto rico students and scientists to participate strongly in future radio sciences projects. this project is jointly funded by the division of astronomical

sciences, the established program to stimulate competitive research (epscor), and the office of multidisciplinary activities in the directorate for mathematical and physical sciences. uprm formed a collaboration with industry and with ao via its managing organization, the university of central florida (ucf), to create the center for advanced radio sciences and engineering. this center provides support to maintain and grow the local scientific and engineering capacity. the center will enable the development of integrated tools to resolve spectrum sharing and coexistence issues, and improve performance on radio science observations. the center's specific goals include the development of enabling technologies in radio frequencies, microwave, and millimeter-wave antennas and systems, electronics and embedded systems, and digital signal processing algorithms, together with crosscutting applied sciences research activities in atmospheric sciences and radio astronomy. tools envisioned for development consist of spectrum monitoring and radio frequency interference (rfi) mitigation systems; interference robust scientific receivers; small size, low weight, low power and low-cost scientific receivers and monitoring systems; and adaptable transmitters with reduced out-of-band emissions. the center includes industry partnerships to develop rfi mitigation solutions. a primary focus is to create new partnerships between academia and industry for the development of the diverse, globally competitive stem workforce required to plan, design, prototype, construct, commission and operate the next generation of radio astronomy instruments. center activities will enhance engineering, radio astronomy, atmospheric science and high-throughput computing research infrastructure at uprm and at puerto rico institutions more broadly, including new faculty lines, support for postdoctoral fellows and graduate students, and cross-institutional research support. education, outreach, workforce, and **\*\*diversity\*\***, equity and inclusion activities will be developed in partnership with the uprm centro universitario para el acceso, and the nrao radio astronomy data imaging and analysis lab project. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: NSF INCLUDES Alliance: Engineering PLUS (Partnerships Launching Underrepresented Students)

Awardee: Northeastern University

Amount: \$8,950,000.00

Abstract: the broader impact of this nsf includes alliance project is nationwide growth in the number of underrepresented minorities and women obtaining undergraduate and graduate engineering degrees. specifically, the project aims to achieve a national target of 100,000/30,000 (bs/ms-phd) degrees for underrepresented minorities and women by 2026 and establish a future growth rate that

can substantially close the gap. engineering depends on team collaboration, and research shows that diverse groups are typically more effective than homogeneous teams when complex problem solving is a critical goal. the u.s. must therefore educate a diverse engineering workforce to encompass the complex technological challenges faced by society. this nsf includes project directly addresses this critical challenge. this alliance will have a broad reach, expanding to 150 higher education institutions in five major regions of the country. the work of the alliance is designed to learn what is most effective at broadening participation in engineering education, particularly at the critical transition points for students. its work will enable wider adoption of best practices through the training of change agents that can work effectively both regionally and nationally. the proposed project has the overarching goal to achieve transformative, systemic and sustainable change that will dramatically increase the number of underrepresented minorities and women obtaining undergraduate and graduate engineering degrees. the alliance will leverage the wealth of best practices for broadening participation in engineering that has emerged from research over the last several decades to provide the collaborative infrastructure needed to support sustainability and scale-up of successful strategies. the intellectual merit of the alliance mission is tied to the research which is aimed at answering the question: how does regional scaling occur across the alliance? three levels of investigation will be pursued; q1) what role does evidence play in scaling the most promising engagement activities across a given region and the alliance overall? q2) how do the social interactions and the resultant networks affect scaling? and q3) what are the historic and operative frameworks of how gender, race and ethnicity, pathway opportunities and goal attainment are addressed? the research results will create new knowledge and help others work toward achieving inclusive participation in engineering. this nsf includes alliance award is funded by: - nsf inclusion across the nation of communities of learners of underrepresented discoverers in engineering and science (nsf includes), a comprehensive national initiative to enhance u.s. leadership in discoveries and innovations by focusing on **\*\*diversity\*\***, inclusion and broadening participation in stem at scale. - broadening participation in engineering (bpe). - louis stokes alliance

for minority participation (Isamp). this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: NSF INCLUDES Alliance: ALRISE - Accelerate Latinx Representation In STEM Education with Institutional Intentionality and Capacity Building for Experiential Learning

Awardee: Arizona State University

Amount: \$7,976,632.00

Abstract: the alrise alliance is developing a network of faculty, staff, administrators, and students at 2-yr and 4-yr hispanic serving institutions (hsis) and emerging hsis (ehsis) to accelerate latinx representation in science, technology, engineering, and math (stem) education. challenges such as (1) campus environments that are not intentionally culturally-responsive to latinx stem students; (2) deficit mindsets of stem educators that devalue latinx students? strength and resilience; (3) latinx stem retention and graduation rates that are significantly lower than enrollment; and (4) the underrepresentation of latinx professionals in stem job clusters compound broadening participation efforts. these factors place a necessity for change on institutions, educators, and employers to intentionally harness latinx students? assets and create a more welcoming environment that fosters reproducible success. the alrise alliance provides professional development for faculty, staff and industry to serve latinx students with intentionality through culturally-responsive undergraduate research and work-based experiential learning. uniquely focused on the intersectionality of latinx stem students and experiential learning, alrise fills an important gap in ongoing broadening participation efforts, with its focus on culturally-responsive experiential learning in an action-oriented and data-driven environment of continuous improvement and collaboration. the networked improvement community (nic) collaborative infrastructure of the alrise alliance will mobilize large-scale change through shared vision, partnerships, common goals and metrics, leadership and

communication, and potential for expansion, sustainability, and scale. the alrise backbone organization, science foundation arizona center for stem at arizona state university, provides leadership and communications structures to connect and collaborate amongst four regional hubs that coordinate a total of 26 hsi/ehsi institutional members and their stem planning educator teams. partner subgroups defined by professional expertise in experiential learning and intentionality, undergraduate research, work-based experiences and advocacy and policy will provide services for assessing and developing intentionality across the alliance. a continuous improvement cycle will be used to effect change locally while also improving the alrise alliance and processes. quantitative and qualitative data will be collected and analyzed at the student, institutional, and experiential learning program levels to provide evidence for practices supported and disseminated by alrise. triangulated findings from multi-level mixed methods research, and outcomes from formative and summative evaluation, will advance knowledge on culturally responsive practices, hsi intentionality, and as-yet undiscovered common challenges and synergies within and across alliance members. instilling intentionality to serve latinx students at the institutional level, and through asset-oriented educator professional development and coaching, will build capacity to effect change at each member institution. this capacity-building approach will not only serve the latinx students actively engaged in experiential learning programs but also retain the knowledge and programs to impact a far greater number of students in the future. the alrise alliance is funded by nsf inclusion across the nation of communities of learners of underrepresented discoverers in engineering and science (nsf includes), a comprehensive national initiative to enhance u.s. leadership in discoveries and innovations by focusing on **\*\*diversity\*\***, inclusion and broadening participation in stem at scale and the improving undergraduate stem education (nsf iuse): hispanic serving institutions (hsi) program, which supports efforts to enhance the quality of undergraduate stem education and to increase the recruitment, retention, and graduation rates of students pursuing associate's or baccalaureate degrees in stem. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: National Cybersecurity Training & Education (NCyTE) Center

Awardee: Whatcom Community College

Amount: \$7,499,995.00

Abstract: keeping computers and information systems secure is a major challenge. business, industry, and government need well-prepared technicians who can prevent, detect, and investigate cybersecurity breaches. the growth of cyber-threats has created a need for many additional workers who have cybersecurity knowledge and skills. as the advanced technological education (ate) program's national center in the area of security technologies, the national cybersecurity training & education (ncyte) center will leverage previous nsf grants, projects funded by the national security agency (nsa), and the expertise of partners to provide leadership for cybersecurity education in community and technical colleges and related secondary school programs that build america's skilled technical workforce in cybersecurity. the center will pursue four strategic goals: (1) expand educational pathways and the **\*\*diversity\*\*** of cybersecurity programs to meet the nation's workforce needs. (2) develop and deploy leading-edge cybersecurity curricula. (3) cultivate engagement with employers (business, industry, government) and career opportunities for students. (4) disseminate resources to improve current and future directions of cybersecurity education. in addition to whatcom community college, major partners in the center include california state university, san bernardino; embry-riddle aeronautical university (daytona beach, fl); eastern new mexico university - ruidoso; the center for systems security and information assurance (cssia; based at moraine valley community college); and the national cyberwatch center (ncc; based at prince george's community college). to advance cybersecurity education and build the nation's cybersecurity workforce, the ncyte center will expand, standardize, and disseminate cutting-edge resources for teaching and learning (including online learning) and best practices aligned with industry standards. the center will develop cybersecurity content targeting new industry sectors, integrate new and updated

cybersecurity concepts into existing fields, conduct associated professional development for college and k-12 educators, and coordinate the work of other ate grantees in cybersecurity. a projected 1,500 faculty will receive training and an estimated 2,300 faculty will engage in annual leadership development workshops and forums to update their knowledge and skills and to learn about needs in industry. academies and boot camps will address the shortage of cybersecurity faculty. through forums and career fairs, an estimated 10,000 students will learn about cybersecurity careers and make connections with employers. these activities, as well as targeted outreach and mentoring activities (with a special focus on women, veterans, and native americans), will attempt to broaden participation in the field. using the materials, methods, experiences, and guidance that the center provides, community colleges around the nation will be able to launch, grow, and maintain cybersecurity programs, ultimately expanding and diversifying the pool of graduates who pursue cybersecurity careers. this project is funded by the advanced technological education (ate) program, which focuses on the education of technicians for the advanced-technology fields that drive the nation's economy. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Phase II CREST Center for Interface Design and Engineered Assembly of Low-dimensional Systems (IDEALS II)

Awardee: CUNY City College

Amount: \$5,100,000.00

Abstract: this award is funded in whole or in part under the american rescue plan act of 2021 (public law 117-2). the centers of research excellence in science and technology (crest) program supports the enhancement of research capabilities of minority-serving institutions through the establishment of centers that effectively integrate education and research. crest promotes the development of new knowledge, enhancements of the research productivity of individual faculty, and an expanded presence of students historically underrepresented in science, technology, engineering, and mathematics disciplines. with national science foundation support, cuny city college will continue development of its phase ii center for interface design and engineered assembly of low-dimensional systems (ideals ii). building upon the salient accomplishments of phase i ideals (ideals i), ideals ii research intends to address the need to strengthen the nation's leadership in materials capabilities in the frontier areas of quantum materials, bioinspired reconfigurable materials, and photonic materials and technologies that address critical national needs, elevating ccny as a premier research institution in these fields. phase ii center investigators and students will pursue frontier research and education transformative goals through extending collaborations, created a multifaced cutting-edge materials research program, fully integrate research and education to enhance student experience and train tomorrow's leaders, and introduce the city college new york presidential postdoctoral fellowship program to enhance faculty **\*\*diversity\*\***. the research thrusts of the nsf phase ii crest center for interface design and engineered assembly of low-dimensional systems (ideals ii) at the city college of new york (ccny), encompass the frontier areas of quantum materials, bioinspired reconfigurable materials and photonic phenomena to address energy, health, and environmental needs. the multi-disciplinary, collaborative research activities are organized into three thematic subprojects. subproject 1, entitled, emergent quantum materials and functions, will focus on materials science and engineering of two-dimensional systems, such as, surfaces and interfaces where band topology and strong electron correlations lead to new functions and quantum phenomena for the next-generation quantum technologies. zero-dimensional systems, such as,

quantum dots and rare-earth ions in host matrices will be utilized as platforms for implementing spin qubits that circumvent the limitations of current schemes of quantum computation. subproject 2, bio-inspired, re-configurable materials to scale, focuses on scalability of reconfigurable materials (materials that change their properties by adapting to an external stimulus) developed in phase i and further explores their specific applications in light harvesting, medical diagnostics and cancer therapy as well as sustainability and environmental rehabilitation. subproject 3, frontiers of photonic materials, phenomena and devices will explore emerging basic ideas, synthesize new materials (such as, hybrid semiconductor heterostructures, topological nanostructures) with unprecedented functionalities, investigate salient properties of the engineered materials, design and test devices (light sources, detectors and quantum sensors) based on promising materials, and provide feedback for materials and device design criteria. the seed project approach will be used as a mechanism for the nucleation of new ideas and exploration of areas of opportunity and growth. an integrated research and education thrust, will continue to apply the proven interventions developed and implemented in ideals i, and introduce new ones, to help produce a talented, inclusive and diverse work force capable of leading the materials research and development endeavors in the 21st century. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: NSF Convergence Accelerator- Track C: QuSTEAM: Convergent undergraduate education in Quantum Science, Technology, Engineering, Arts, and Mathematics

Awardee: Ohio State University

Amount: \$4,989,414.00

Abstract: the nsf convergence accelerator program supports use-inspired, team-based, multidisciplinary efforts that address challenges of national importance and will produce deliverables of value to society in the near future. the goal of this project is to develop qusteam (quantum information science, technology, engineering, arts and mathematics), a transformational undergraduate curriculum that will provide a national educational model for the emerging field of quantum information science and engineering (qise). the intellectual merit of this project is in development of a qusteam curricular structure using evidenced-based research to determine the scientific and engineering practices that will be required of the future quantum smart workforce. our curriculum will serve as a national standard for qise education. this new curricular structure will be designed from the ground up to address structural barriers that have to date limited the **\*\*diversity\*\*** and inclusiveness of stem training and will include concurrent training in the societal impact of qise technologies by incorporating content beyond traditional stem disciplines. the key outputs of our research will be: (i) a schematic of interdisciplinary modules that details how the building blocks of qise-competency can be organized for different educational targets (module, class, minor, and certificate). (ii) a map of steps taken to actively promote equity and inclusivity in the curriculum that will serve as a model for future curricular development. (iii) individual course curricula that demonstrate the implementation of qusteam. the broader impacts of this project will be in creation of a quantum smart workforce will have a transformative effect on the us economy and

society. the qusteam curriculum, and the methodology used in developing it, will be made publicly available to serve as a template for the development of convergent curricula in other subjects. "" this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Engineering for US All-E4USA: A National Pilot High School Engineering Course and Database

Awardee: University of Maryland, College Park

Amount: \$4,961,444.00

Abstract: the aim of the engineering for us all (e4usa): a national pilot program for high school engineering course and database project is to demystify and democratize engineering through a program targeting high school students and teachers that will by nature benefit society and advance the desire for a more diverse future engineering workforce. the program expands the pool of teachers capable of teaching engineering and the number of students considering further education and/or a career in engineering. the knowledge taught by empowered teachers will provide a broader understanding of engineering intended to excite an interest in pursuing additional engineering education. specific efforts to collaborate with a diverse group of schools (urban, suburban, rural, private, public, parochial, single gender, etc.) will ensure that this program reaches those who have previously been unable to offer engineering and/or traditionally underrepresented in engineering. partnerships with post-secondary institutions will also create and facilitate pathways for students to explore possible engineering careers. scaling and sustaining e4usa will allow the project to address the desired societal outcome of a more educated citizenry and increased numbers and **\*\*diversity\*\*** of students joining the future engineering workforce. continued support for e4usa will establish the program as major contributor in the field of engineering and technological literacy, while bringing engineering truly to all.      engineering for us all (e4usa): a national pilot program for high school

engineering course and database's primary goal is to demystify and democratize the learning and practice of engineering by engaging high school students and teachers in a project-based engineering curriculum. e4usa will increase engineering literacy for all and expand opportunities for those traditionally underserved and underrepresented in engineering to pursue careers as engineers. current nsf funding has led to the creation of the e4usa curriculum, teacher professional learning (e.g., professional development workshops and community of practice), and additional supporting resources (e.g., mydesign®). this first of its kind program presents the engineering field using four big ideas: 1) discover engineering, 2) engineering in society, 3) engineering professional skills, and 4) engineering design. this design and development grant is intended to support efforts to scale, study, and sustain e4usa over the next three years. school settings will be broadened by expanding the reach of e4usa to 50 teachers and approximately 5,000 students nationwide. design-based implementation research (dbir) capturing participating student and teacher data will continue and expand to include five in-depth case studies. knowledge gained will inform central components of e4usa intended to improve developed resources, expand partnerships, garner insights into the impacts of e4usa, and increase pathways for credit and placement these insights, in conjunction with the creation of an oversight and advocacy agency, will provide the foundation for e4usa becoming a self-sustaining, independent entity supported by key partners like teachengineering. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Community College Presidents Initiative - STEM (CCPI STEM)

Awardee: Prince George's Community College

Amount: \$4,638,192.00

Abstract: according to the national science board, by 2022 the u.s. will experience a workforce shortage gap of approximately 3.4 million skilled technical jobs. this and other similar statistics are a call to action for community colleges to address the impending shortage and existing need for stem education and workforce development. this project, the community college presidents initiative in stem (ccpi-stem), serves the national interest through its efforts to galvanize, enlighten, and inspire community college leadership including college presidents, board members, and vice presidents to promulgate and support local, state, and regional stem education, nsf ate funding, and workforce development on their campuses. the project has two major emphases: (a) the important leadership role of administrators and boards of trustees in community college external funding for stem education, and (b) the institutional infrastructure and capacity necessary for effective grant development and implementation, overcoming challenges to success. four objectives will guide

the execution of this project. first is to catalyze the engagement of community college presidents, boards of trustees, and other senior administrators in developing stem action items for their colleges and communities. second is to identify and analyze the needs and issues of interest and importance to community college leaders by region. third is to develop and pilot test instructional curricular materials for existing and future community college presidents and leaders that will strengthen their understanding of stem education issues. fourth is to strengthen collaborations with the business community that investigate and promote the economic impact of the ate program. seven regional networks (rns), each led by a community college president in close collaboration with national organizations including aacc, acct, and the league of innovation, as well as with representatives of business and industry will be developed. each rn will formulate its own list of initiatives with input from member community colleges, businesses and its community at large. ccpi-stem will also work with external organizations, such as economic modeling specialists intl. (emsi) and burning glass, to assess the economic impact of ate awards in select colleges. curricular materials on ate funding and program implementation will be developed and tested in collaboration with leaders of community college graduate programs. **\*\*diversity\*\***, equity, and inclusion in stem education will be addressed in the initiatives of the rns and through the prism of external funding and institutional infrastructure. ccpi-stem results will be broadly disseminated through the rns, a website, and national, regional and local conferences and venues. specific guides and publications, including "models that work," will be developed and broadly disseminated. the ccpi-stem annual summit, to be held in conjunction with the aacc national convention, will provide a forum for interaction and dissemination on a national level. this project is funded by the advanced technological education program that focuses on the education of technicians for the advanced-technology fields that drive the nation's economy. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: RESEARCH-PGR/NSF-BSF: Identification and Functional Dissection of Shared Cis-Regulatory Elements Controlling Quantitative Trait Variation Across Angiosperms

Awardee: Cold Spring Harbor Laboratory

Amount: \$4,046,050.00

Abstract: crop plants provide food, feed for livestock, and other essential materials. breeders are continuously improving our crops; however, there is an urgent need to accelerate crop improvement in the face of climate change and limited resources. natural genetic variation in the form of dna mutations is widespread in crops, and is the starting material for their improvement, but such variation is often not useful or is unpredictable in its effect on plant growth. genes that control important yield traits are expressed at specific levels, locations and times during plant growth, and tuning these expression programs may enhance crop productivity. gene expression is controlled by regions of dna surrounding genes known as cis-regulatory elements. despite their fundamental biological significance, the identification of such elements and their use in agriculture has been challenging. this research project, a collaborative effort between scientists at cold spring harbor laboratory, the university of massachusetts-amherst, and the hebrew university of jerusalem, will predict regulatory elements using a newly developed computational algorithm, conservatory, combined with existing genome sequences from many plant families. these elements will then be modified using crispr genome editing tools. these new variants will be tested for changes in phenotype that lead to improvements in yield and other important agronomic traits. the project will train young scientists at various levels, as well as promote outreach and education in plant genomics in partnership with genspace, a community biology lab in brooklyn, ny. the project will develop a new curriculum for high school students from under-resourced title i schools and demographic groups historically excluded from the life sciences to explore applications of crispr in agriculture, including hands-on labs in plant transformation and crispr editing. this project will test the hypothesis that genes with conserved functions are regulated by deeply conserved cis-regulatory elements (cres) across angiosperms, and that characterizing these cres will provide a

new level of understanding in linking genotype to phenotype. the project will exploit the recent explosion in high-quality sequenced genomes to identify conserved regulatory elements across angiosperm **\*\*diversity\*\*** using the conservatory algorithm. the functions of the elements identified by conservatory will be tested by precise genome editing, with a focus on developmental regulators and architectural traits. functional dissections will be performed in two species in each of three diverse plant families, spanning eudicots and monocots, which will allow the assessment of cre functional evolution over shallow and deep timescales. the catalog of conserved regulatory elements identified, and the editing strategies developed to test their functions, will reveal fundamental principles governing gene expression control and will accelerate innovative approaches to fine-tune crop productivity traits. critically, the tools, techniques and fundamental principles emerging from this multi-disciplinary project will comprise a valuable community resource, enabling the engineering of diverse systems and phenotypes, such as biotic and abiotic stress tolerance, nutritional quality, and symbiosis. all project outcomes will be widely accessible through long-term public data and genetic repositories. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Awardee: University of Kansas Center for Research Inc

Amount: \$4,000,000.00

Abstract: millions of tons of plastic waste pollute the environment with adverse ecological and health impacts. new technologies are urgently needed to facilitate plastic recycling and enable the growth of a circular and sustainable economy. such a transition requires technological innovation and public policies that enable the reuse of used polymers in new products, as well as renewable raw materials such as grasses and crop leftovers. in this project, researchers from the university of kansas (ku), university of delaware (ud), and pittsburg state university (psu) will use their complementary expertise to develop the knowledge to foster this transition. the team aims to develop novel catalysts and processes to (a) transform biomass feedstocks into commercially relevant plastic materials, and (b) deconstruct recycled plastics efficiently into precursors for reuse. simulations, data science, techno-economic analyses and life cycle assessments will guide the research. concurrently, public policies will be formulated and evaluated to drive rural economic growth and the market penetration of the new materials. such activities will spawn an agro-based, renewable materials manufacturing industry in kansas, delaware and beyond, providing a major economic boost in these two epscor jurisdictions. the program will mentor junior faculty and establish a postdoctoral program for faculty **\*\*diversity\*\*** to support women and underrepresented minorities in

this career path. additionally, we will recruit and educate a diverse workforce equipped with the skills needed to use advanced manufacturing concepts to drive our economy towards sustainability.

specifically, the project will develop novel synthesis routes for a broad slate of renewable polyesters and polymer recycling strategies, signaling a new benign by design paradigm for the advanced manufacturing of sustainable materials. the program will focus on three renewable monomers: 4,4'-biphenyl-dicarboxylic acid, 5,5'-bifurandicarboxylic acid, and sebacic acid. these were selected because they can be synthesized from biomass-derived furfural. since recycling will involve renewable and fossil-based plastics for the foreseeable future, the project will evaluate and optimize copolymers of these renewable monomers with the existing poly(ethylene terephthalate) (pet) plastic. the convergent research expertise of our team of investigators will enable integration of catalysis and kinetics fundamentals with separations and process intensification strategies to develop scalable manufacturing and recycling concepts. novel catalytic materials including biocatalysts, intensified spray and microwave reactors, and new fundamental knowledge underlying the synthesis and recycling of polymers will emerge. a framework for analyzing cradle-to-cradle process systems blended with sustainability principles, economics and public policy considerations will be developed. we will deploy and advance state-of-the-art data science methods and multiscale modeling to expedite discovery and innovation of renewable and recyclable biobased polymers. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: RII Track-2 FEC: Genome Engineering to Sustain Crop Improvement (GETSCI)

Awardee: University of Hawaii

Amount: \$3,993,756.00

Abstract: improved and practical crop breeding tools are required to meet the increasing demands of a growing global population and to overcome the sudden and variable stresses, made worse, by climate change. this project brings together researchers from the university of hawaii at manoa and iowa state university to develop an efficient, robust genome engineering toolkit that can be used to speed the generation of resilient crops adapted to a changing environment. reproductive barriers are a major bottleneck that limits the genetic **diversity** available for crop improvement. tropical maize germplasm is a rich source of genetic **diversity** but its flowering behavior in temperate regions precludes its broad use for maize improvement. to access this **diversity**, our two institutions formed a collaboration that integrates our strengths in tropical plant biology and transformation (hawaii) with maize transformation, genome engineering, and breeding (iowa). our goals are to establish a rapid and efficient genetic transformation platform and to develop improved genome editing tools to reprogram the flowering behavior of high-yielding tropical maize lines allowing their incorporation into any maize breeding program. both hawaii and iowa will gain a valuable new capability in genetic transformation and genome engineering which will transform the types of crop research possible at both institutions. expected impacts from this project will help address food

security and economic weaknesses in hawaii, by allowing for the development of new tropical crop breeding industries. in iowa, access to gene-edited temperate-adapted tropical germplasm will move maize improvement into the next era of genome-optimized breeding. workforce capacity will be increased by engaging underrepresented students, particularly native hawaiians and pacific islanders, in diverse aspects of genome engineering research, by the exchange of undergraduates between partner institutions to prepare a globally competitive, multiculturally, and socially responsible workforce, and by creating opportunities for improved science communication skills through training sessions, workshops, and engagement with the community to communicate the value and safety of these new tools. critical to our future is maintaining the rate of genetic improvement of the crops that feed us and sustain our economy. but the sudden and increasingly severe stresses caused by climate change limit the pace of improvement. advances in genome engineering offer rapid solutions by enabling precise and targeted reprogramming of molecular networks to improve crop performance. the rich genetic **\*\*diversity\*\*** in tropical maize is largely underutilized for maize improvement because tropical lines are photoperiod sensitive and flower late in the long-days of temperate growing regions. to access this **\*\*diversity\*\***, we formed a collaboration between the university of hawaii at manoa (uh manoa) and iowa state university (isu), which integrates strengths in tropical plant system biology and transformation (uh manoa) with maize transformation, genome engineering, and breeding (isu). our goal is to use gene editing to suppress the photoperiod response in elite, high-yielding tropical maize to promote earlier flowering. these edited tropical lines can then be used to enhance any maize breeding program. our objectives are to (1) establish an efficient, germplasm-independent maize transformation platform, (2) develop a facile, tractable genome editing toolkit to suppress the photoperiod response in six tropical inbreds, (3) analyze photoperiod network function in genome edited tropical lines, and (4) improve skills in communicating the value and safety of these new genome engineering tools. the outcomes from this project include new tropical maize transformation capabilities at both jurisdictions, genome editing reagents for modulating flowering in maize, six elite tropical inbreds adapted to temperate

breeding programs, a mechanistic understanding of the response to reprogramming the flowering network, and improved skills to communicate the value of this technology in professional and public contexts. broader impacts expected from this project include opening this technology to academic labs, that can build research capacity by allowing genome engineering of diverse crops. democratizing these tools are expected to speed breeding advancements, sustain crop improvement efforts, and spur economic growth. both hawaii and iowa will gain a valuable new capability in maize transformation and genome engineering, and will transform the types of crop research possible at both institutions. in hawaii, this project will help address food security and economic weaknesses revealed by the pandemic, by allowing for development of new tropical crop breeding industries. in iowa, access to gene-edited temperate-adapted tropical germplasm moves maize improvement into the next era of genome-optimized breeding. workforce capacity will be increased by engaging underrepresented students, particularly native hawaiians and pacific islanders, in diverse aspects of genome engineering research, by the exchange of undergraduates between partner institutions to prepare a globally competitive, multiculturally, and socially responsible workforce, and by creating opportunities for improved science communication skills through training sessions, workshops, and engagement with the community to communicate the value and safety of these new tools. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: CyberCorps Scholarship for Service (Renewal): Secure Computing Initiative

Awardee: New Jersey Institute of Technology

Amount: \$3,825,496.00

Abstract: this new jersey institute of technology (njit) project will continue and expand the secure computing initiative (sci) as part of the cybercorps®: scholarship for service (sfs) program. sci is

designed to prepare the next generation of cybersecurity professionals to fulfill the national need for cybersecurity experts, while promoting **\*\*diversity\*\***, learning, and discovery. sci has been successful in recruiting, training, and placing highly qualified cybersecurity experts in government positions since 2016. the sci project recruits students in their junior or senior undergraduate year and supports them through the completion of one of two cybersecurity master's degrees offered at njit: ms in cyber security and privacy or ms in information technology administration and security. the project also includes several activities to recruit a diverse student body, such as working with the njit's murray center for women in technology to enhance gender **\*\*diversity\*\***, collaborating with the njit chapters of hispanic and african american professional societies to enhance racial/ethnic **\*\*diversity\*\***, and cooperating with the njit's educational opportunity program office to recruit students from disadvantaged socio-economic backgrounds. the sci cybersecurity education model is characterized by seven features: flexible cybersecurity curricula, experiential learning, research-supported education, nurturing students' creativity, a cybersecurity technology watch activity, fostering students' abilities to work under stress, and multi-tier mentoring. njit has a strong commitment to cybersecurity education, demonstrated by more than 40 courses that focus on this area. as a result, njit's undergraduate and graduate programs allow the sci students flexibility in choosing their area of cybersecurity specialization. in addition, sci incorporates experiential learning projects that map to the national initiative for cybersecurity education (nice) cybersecurity workforce framework. sci scholars are required to participate in a research project with a mentor drawn from a pool of research-active faculty who teach and conduct research in cybersecurity. creativity is stimulated through training in design-thinking approaches for research projects and working in interdisciplinary teams. to keep the students abreast of evolving cybersecurity threats, sci organizes a cybersecurity technology watch, which consists of investigating recent cybersecurity breaches, analyzing them, and drawing lessons from them. to develop appropriate skills for work under stress, the sci students participate in cybersecurity competitions, in which they typically have to solve practical problems in a limited amount of time. finally, sci is structured for a multi-tier mentoring

approach that includes guidance/feedback both from the pis and peers serving as mentors. in addition to training the next generation cybersecurity workforce, sci also produces scientific results and publicly available software that helps advance the discipline of cybersecurity. many of the sci activities involve contact with the general public and are likely to sensitize society at large to the importance of cybersecurity. the outreach activities also include enrichment programs that focus on cybersecurity education for high school students. this project is supported by the cybercorps® scholarship for service (sfs) program, which funds proposals establishing or continuing scholarship programs in cybersecurity and aligns with the u.s. national cyber strategy to develop a superior cybersecurity workforce. following graduation, scholarship recipients are required to work in cybersecurity for a federal, state, local, or tribal government organization for the same duration as their scholarship support. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: BPC-AE: Equity in Computing Education Policies, Pathways, and Practices (ECEP 3)

Awardee: University of Texas at Austin

Amount: \$3,599,041.00

Abstract: we live in an increasingly technology-dependent world where computational literacy and an understanding of computing's implications on individuals and society are vital to personal success, healthy and engaged communities, and to our nation's economic competitiveness and security. the lack of **\*\*diversity\*\*** in k-12 computer science education, limits our nation's ability to leverage the full range of expertise and creativity present in our classrooms and communities. the equity in computing education policies, pathways, and practices (ecep 3) alliance will address the persistent problem of the lack of **\*\*diversity\*\*** in k-12 computer science education and computing pathways. as a result of ecep support, state leaders will untangle the complex web of factors that produce inequitable outcomes for marginalized students, interrogate their own state data to identify specific student populations that have been excluded from computing pathways, investigate their state's educational ecosystems and policies to determine the root causes of disparities in access and participation in computer science education, and promote equity-explicit policy changes to address systemic barriers to broadening participation in computing. ecep will help our nation to transform the exclusionary systems that lead to disparities in cs education for k-12 students, thus leading to a

more diverse computing workforce and computationally literate citizenry. the ecep team is led by the university of texas at austin, the massachusetts green high performance computing center, indiana university bloomington, and university of california irvine. ecep builds state-level capacity for systemic change, thus laying the foundation for improvements in equitable capacity for, access to, participation in and experiences (cape) of computer science education for students who have been excluded from computer science education (csed) pathways. ecep's mission, grounded in the collective impact model, is to change the deeply ingrained policies, pathways, and practices that perpetuate inequitable outcomes throughout the k-12 csed ecosystem. ecep has four primary goals: 1) ecep will serve as a national hub for state leaders dedicated to collaboratively increasing the number and **diversity** of k-12 students in the pipeline to computing and computing-intensive degrees; 2) state leaders will leverage ecep to develop, advocate for, implement, and share equity-explicit, state-initiated policies, pathways, and practices that promote broadening participation in computing (bpc); 3) utilizing the cape framework, state teams will develop goals, common metrics, and data systems to track progress toward equitable k-12 csed; 4) state teams will implement strategies to increase capacity for and diverse student access to, participation in, and experiences of k-12 csed. in order to accomplish these goals ecep will facilitate and nurture a robust learning community among state leaders through monthly virtual meetings, co-sponsorships to states that seed fund bpc interventions and research projects, coaching of state teams, and technical assistance for the creation of cs landscape reports, state csed summits, and other equity-explicit interventions that help states to advance their bpc goals. ecep also supports the national dissemination of equity-explicit professional development for k-12 teachers through its scaling inclusive pedagogy project and its partnership with the computer science teachers association. a defining feature of ecep is the common metrics project, which will result in tools and protocols for consistent measurement cape outcomes. ecep's research and coaching will support state leadership teams as they establish goals for bpc, evaluate the efficacy of their bpc initiatives, and track their progress longitudinally. this award reflects nsf's statutory mission and has been deemed

worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: FIU-2D Crystal Consortium Partnership for Research and Education in Materials

Awardee: Florida International University

Amount: \$3,471,655.00

Abstract: the fiu-2dcc partnership for research and education in materials (prem) between florida international university (fiu) and the 2d crystal consortium materials innovation platform (2dcc mip) at the pennsylvania state university (penn state), will function as a science and education platform between fiu and 2dcc with the ultimate goal of increasing **\*\*diversity\*\*** in materials research. fiu, a premier minority serving institution located in miami, florida, enrolls 58,928 students combining all levels of academic instruction, with 79% of students from an underrepresented minority in stem (more than 65% hispanic or latino and more than 12% black or african american), and 57% women, is uniquely positioned to promote broadening participation in stem fields. fiu-2dcc prem will integrate transformative research with innovative education and outreach to promote recruitment and implement participation of over 30 ph.d., over 20 m.s. and over 40 b.s. students, the majority being from underrepresented minority groups in stem and women. the students will be immersed in a research-intensive environment to gain expertise in quantum materials research and will be provided with a 360-degree toolkit for success, comprising dual mentoring by faculty at both institutions, access to experts and instrumentation, and career skills training. through the student exchange initiative, the team will grow in **\*\*diversity\*\*** and drive innovative problem-solving. through the prem, fiu will become a materials research hub in south florida while enriching the collaborative partnership with 2dcc mip at penn state. the research outcomes will be disseminated through peer-reviewed articles and conference presentations, and the student success will be publicized through the dedicated project website and outreach events. the project will lead to a sustainable pipeline of

minority students and women joining the materials science workforce. the interdisciplinary research of fiu-2dcc prem will enable uncovering of phenomena related to quantum emission in two-dimensional (2d) materials, the realization of 2d-materials based quantum converters, and understanding of the mechanical properties governing the interfaces between the 2d quantum materials and the substrates supporting their integration into future quantum devices. the prem team will focus on fundamental and practical aspects of new 2d materials and processes that can be transformative in the emerging field of quantum science and provide advanced characterization methods to ensure long-term 2d resilience in future quantum devices. organized in three major thrusts, the collaborative research will focus on: (1) novel 2d quantum dots for developing single photon emitters useful in quantum science; (2) layered crystals with optical nonlinearity for developing 2d quantum frequency converters; and (3) mechanical behavior of stand-alone and substrate-deposited 2d materials, assisted by predictive models to support 2d materials discovery and atomic-level characterization of 2d materials. the user facilities at 2dcc mip of penn state, along with unique equipment at fiu, will accelerate quantum materials discovery and enable cross-disciplinary student training. ultimately, this research partnership will increase the understanding of fundamental mechanisms governing room-temperature 2d quantum emission, generate layered crystals for miniaturized quantum converters, and pave the way for scalable quantum computing, with potential to deliver significant societal progress. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: CyberCorps Scholarship for Service (Renewal): Strengthening Cyber Community and Pathways Using Research Experiences, Technical Training and Institutional Outreach

Awardee: Pace University New York Campus

Amount: \$3,415,224.00

Abstract: this project supports the continuation and expansion of pace university's cybercorps® scholarship for service (sfs) program. over the next five years, the program will recruit new sfs scholars to study cybersecurity in order to support the government in securing its cyber defense and operations. the new scholars will come from the bachelor's, master's, and doctoral levels of the institution's academic programs in computing and from community college partners, including the state university of new york - westchester community college, a minority-serving institution. students will form a community of cybersecurity scholars who inspire each other and work together in various activities, including workshops, competitions, and conference participation. in addition, the program will support the cybersecurity student club as a means to further broaden the community. the sfs scholars will engage in research, technical training, and professional certification preparation to ensure they will be ready to meet rapidly evolving cybersecurity challenges. lastly, the project will continue its commitment to **\*\*diversity\*\*** through institutional outreach to k-12 schools and community colleges and focusing on recruiting students from underrepresented minority backgrounds and on women. pace university's program has produced cybersecurity professionals working at various levels of the government. the objectives of the project are 1) to produce twenty or more cybersecurity professionals who will enter the government workforce upon graduation, 2) to prepare cybersecurity professionals with diverse educational backgrounds through five cyber pathways, 3) to support **\*\*diversity\*\*** in the field by providing opportunities for minority students and women, 4) to mentor non-sfs institutions and their students through institutional partnerships, 5) to strengthen collaboration between pace university and its government partners, and 6) to generate interest in becoming cybersecurity professionals among broader student populations both at pace university and at partner institutions. the program consists of five cyber pathways ranging from an associate's degree to the phd. the pathways allow the program to prepare scholars differently based on their background and interests. in addition, scholars will engage in research projects that reinforce their cybersecurity competencies. these research projects, with support from the cybersecurity scholars, have the potential to contribute to research innovation in the areas of

open-source intelligence, data analytics, machine learning, computer forensics and robotics. professional development activities will expose scholars to cybersecurity professionals from academia and industry. this project will use competency-based advising, using digital badging to provide scholars with a roadmap aligned to their strengths and interests and with the nice cybersecurity workforce framework. this advising approach, accompanied by the five cyber pathways, curriculum integration and the research program, will enable the project team to recruit and prepare students to satisfy diverse needs for cybersecurity professionals in the government. this project is supported by the cybercorps® scholarship for service (sfs) program, which funds proposals establishing or continuing scholarship programs in cybersecurity and aligns with the u.s. national cyber strategy to develop a superior cybersecurity workforce. following graduation, scholarship recipients are required to work in cybersecurity for a federal, state, local, or tribal government organization for the same duration as their scholarship support. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: CyberCorps Scholarship for Service (Renewal): An Enhanced and Integrated Scholar Experience in Cybersecurity

Awardee: Tennessee Technological University

Amount: \$3,280,630.00

Abstract: the renewal of the tennessee tech university (tntech) project will allow this cybercorps®: scholarship for service (sfs) program to continue supporting national defense through the production of well-trained cybersecurity professionals. the program supports the success of the sfs scholars by combining integrated experiences in education, research and outreach and leveraging existing resources and university-wide collaboration among faculty and administration. the tntech cybercorps® program supports both undergraduate and graduate students with a focus on

improving the **diversity** of the cybersecurity workforce through increasing the representation of women and underrepresented minorities. in addition, the program is the first in the state of tennessee with the opportunity to serve the economically distressed appalachian region. with the rapid growth of tech's computer science and cybersecurity program, the renewal allows tntech to continue to produce highly trained cybersecurity professionals who contribute to the nation's cyberspace security. it also allows new innovations in the sfs program and enables the cybersecurity education research and outreach center at tntech to continue deepening its local, regional, and national impacts. the objectives of the tntech sfs program include continuing to expand higher education choices in cybersecurity for local and regional students through federal scholarship opportunities. the project will also enhance sfs scholars' knowledge, skills, research aptitude, and service-learning motivation through a program that values fair participation in education, research and outreach. the program will continue supporting the pipeline of sfs scholars to federal agencies in tennessee (and the region) while aiming to increase women and underrepresented minority students' participation. program performance will continue to be assessed in this new project period. the project continues to refine strategies and techniques that can potentially be effective in addressing sfs program management challenges including scholar on-boarding and providing wide-ranging experiences and flexible paths for scholars. this project is supported by the cybercorps® scholarship for service (sfs) program, which funds proposals establishing or continuing scholarship programs in cybersecurity and aligns with the u.s. national cyber strategy to develop a superior cybersecurity workforce. following graduation, scholarship recipients are required to work in cybersecurity for a federal, state, local, or tribal government organization for the same duration as their scholarship support. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: NRT-HDR: Bridges in Digital Health

Awardee: West Virginia University Research Corporation

Amount: \$3,062,662.00

Abstract: proposal id: 2125872 proposal title: nrt-hdr: bridges in digital health pi: donald adjero

institution: west virginia university public abstract the rapidly increasing cost of healthcare represents one of the most pressing problems facing the united states and most other countries around the world. at the same time, increased life expectancy has resulted in a significant expansion of the nation's elderly population. the combination of rising health care costs and increased life spans poses tough challenges for many families. the widespread disruptions caused by the covid-19 pandemic have exacerbated these national challenges and health disparities, particularly in rural communities with poor health rankings. these problems could be addressed by new advances in digital health (dh) and how we train the next generation of scientists, engineers, and healthcare professionals to develop and deploy such advances. this national science foundation research traineeship award to west virginia university (wvu) will address these challenges by developing a new graduate education and traineeship model to prepare professionals who can work in collaborative transdisciplinary teams to develop and apply data science and artificial intelligence (ai)

techniques in addressing difficult problems in dh, including in rural areas. the project anticipates training twenty-four (24) funded and forty (40) unfunded ms and phd students from different backgrounds, including engineering, computer science, medicine, health sciences, physical sciences, and economics. data science and ai techniques have been successfully applied to address a diverse range of health problems. the traineeship will address how to scale and build on dh successes by developing: 1) effective and transferable frameworks for training a larger and more diverse workforce with the foundations underlying these advances while inculcating soft skills beyond traditional coursework and ensuring rural communities are served; and 2) new ways to address other problems in dh related to the nature of dh data, the significant data analysis gap, and computational problems. a key element in the traineeship is its specific attention to the "bridges" required for effective and scalable traineeship and workforce development in dh. these bridges will connect: (a) different fields within health sciences, and across other areas, including barriers posed by the distinct terminologies used by different fields; (b) different scales of study in biomedicine (from micro to macro) via integration of different data types; and (c) underrepresented groups and innovative research in dh to ensure "diversity" in the traineeship. this "diversity" will be achieved by: 1) recruiting and supporting success for participants from historically black colleges and universities, those who are rural, those from the first generation in their families to go to college, and/or those from other groups underserved in stem, and 2) by bridging primarily undergraduate institutions and large research institutions. trainees will develop novel approaches to tackle some of the core problems in ai (e.g., trust and safe decision making, scalable data structures, and attention-based information integration). trainees will apply these approaches to specific problems in health, such as myocardial fingerprinting from echocardiograms and large-scale functional annotation in genomics. the project uses an innovative sequence of components to interweave the research theme, important professional skills (e.g., communication, ethics, leadership, collaboration), and coursework into the traineeship model without extending time-to-degree. upon completion, trainees will be awarded a certificate in dh. the traineeship will also form a basis for a

new, transdisciplinary phd program in dh at wvu. the nsf research traineeship (nrt) program is designed to encourage the development and implementation of bold, new potentially transformative models for stem graduate education training. the program is dedicated to effective training of stem graduate students in high priority interdisciplinary or convergent research areas through comprehensive traineeship models that are innovative, evidence-based, and aligned with changing workforce and research needs. this project is jointly funded by the nrt program and the established program to stimulate competitive research (epscor). this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Awardee: University of Texas at El Paso

Amount: \$3,003,188.00

Abstract: the central role of software in the operation of defense, energy, communication, transportation, and manufacturing systems makes it increasingly important that these systems are designed in a way that integrates cybersecurity principles. the renewal of the cybercorps® scholarship for service (sfs) program at the university of texas at el paso (utep) will continue the support of highly qualified students, in particular latinx and female students, who complete a cybersecurity-focused program and graduate with the ability to apply disciplined software development principles and processes. utep is uniquely positioned to contribute to efforts to improve **\*\*diversity\*\*** in the cybersecurity workforce due to the population it serves, which includes hispanic, first generation, and lowest income quartile students. utep students do not fit the "traditional" student profile of a full-time student transitioning directly from high school to a four-year college or university as many students transfer from local community colleges and pursue their education

part-time. over the past five years, utep has made significant advances in developing cybersecurity educational programs, research, and outreach activities at utep and beyond. these efforts have resulted in recognitions including the national security agency designation as a center of academic excellence in both cyber defense and cyber operations (only one of 21 across the nation), as well as the designation as an army research lab-south remote campus in cybersecurity. utep's sfs scholars complete rigorous educational programs with a focus on cybersecurity and complement the knowledge gained in the classroom through significant involvement in cybersecurity research, training, competitions, and hands-on activities. all utep sfs scholars are also required to engage in service to the community to build cybersecurity awareness and capabilities among utep students and beyond. the goals of the utep sfs program are to 1) recruit and retain at least 30 students into utep's master of science in software engineering and the doctoral computer science programs; 2) graduate students who will enter the workforce with the ability to transfer state-of-the-art cybersecurity techniques and approaches into practice; 3) place students in government positions that utilize their knowledge and capabilities in cybersecurity, with a focus on placing graduates in federal/executive entities; and 4) advance cybersecurity awareness and competencies among k-12 students and educators. this project is supported by the cybercorps® scholarship for service (sfs) program, which funds proposals establishing or continuing scholarship programs in cybersecurity and aligns with the u.s. national cyber strategy to develop a superior cybersecurity workforce. following graduation, scholarship recipients are required to work in cybersecurity for a federal, state, local, or tribal government organization for the same duration as their scholarship support. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: NRT-WoU: Establishing Multimessenger Astronomy Inclusive Training (EMIT)

Awardee: Vanderbilt University

Amount: \$3,000,000.00

Abstract: this national science foundation research traineeship (nrt) award to vanderbilt university will prepare the first generation of students in the emerging field of multimessenger astronomy (mma). with the discovery of gravitational waves, there is a new window on the universe and with it, a once-in-a-generation opportunity to launch a new field. the goal of this program is to pilot the establishing multimessenger astronomy inclusive training (emit) initiative. emit will be a transdisciplinary graduate program that promotes **\*\*diversity\*\*** and inclusion and produces scholars with the skills needed to drive discoveries in mma while expanding the stem workforce. the project will train 300 students from physics, astronomy, math, and engineering, including 19 funded trainees, through new formal curricula, seminars, summer programs, and research. the aim is to build a community of practice that is diverse from the outset through cohort building, shared research experiences, visible underrepresented minority role models, and a suite of evidence-based programming designed to promote inclusive excellence. emit trainees will learn the interdisciplinary concepts, research techniques, and the conduct of research critical to advance mma. using educational research-supported practices, the program will prepare students to take a team science approach while developing transferable skills for transition to the workforce. some trainees will earn a master of science degree at fisk university, a collaborating institution, and may directly enter employment or go on to join a ph.d. program. other trainees will enter vanderbilt directly in a doctoral program. regardless of the option chosen, students will earn a graduate certificate in mma through research, coursework, and outreach. joint student research between fisk, vanderbilt, and external collaborators will bring together new nodes of expertise. these collaborative research projects will complement and enhance the strengths of the partnering institutions. the team will provide stage-specific professional development for the entire student training period. the program supplements traditional coursework with a novel modular curriculum specific to mma. some courses and blast modules will be posted on an emit youtube channel to reach the larger community. a summer workshop, open nationally, will occur every other year and broaden

understanding of the research needs, promote the skills required for mma, and further stimulate teaching and communication for emit trainees. after earning the graduate certificate, emit trainees will help lead this workshop. the nsf research traineeship (nrt) program is designed to encourage the development and implementation of bold, new potentially transformative models for stem graduate education training. the program is dedicated to effective training of stem graduate students in high priority interdisciplinary or convergent research areas through comprehensive traineeship models that are innovative, evidence-based, and aligned with changing workforce and research needs. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: NRT-AI: Digital Transformation of Development (DTOD)

Awardee: University of California-Berkeley

Amount: \$3,000,000.00

Abstract: over the past two decades, a massive amount of digital information has become available on every aspect of human existence, from income and climate to housing and health. combining these data from the internet of things, and drawing on techniques for analyzing them through artificial intelligence/machine learning (ai/ml), is now considered crucial for progress in all sectors. digital transformation is the staple of multiple sectors of industry and commerce. however, more far-reaching consequences of digital transformation for poverty alleviation, humanitarian assistance, disaster relief, and, more generally, improving outcomes for under-resourced or low-income populations are understudied. this national science foundation research traineeship (nrt) award to the university of california-berkeley will allow us to provide interdisciplinary training for our students in design methodologies, algorithms, and problem-solving approaches to substantively analyze, ethically investigate, and develop verifiable, fair, inclusive, and useful observations from datasets and models. from these insights, students will be able to devise and deploy digital tools to accelerate growth for low-income populations in the u.s. and globally. the project anticipates training 100 master's and doctoral students, including 28 nrt-funded trainees, from any degree program at the university that expresses interest in researching digital transformation of development (dtod). a key concern has been how the analytics and other mechanisms developed using big data benefit the populations surveyed. by ensuring that the analytic techniques and algorithms, privacy, fairness, mechanism design, and implementation of digital technology are relevant to under-served populations, the dtod traineeship also expects to increase **diversity** and inclusion of members of underrepresented minority groups in stem. the dtod program will include interdisciplinary research activities, formal coursework and curriculum building, immersive lab and field training, the creation of official dtod concentrations at both the doctoral and master's degree levels, and career development. in addition, the program's effectiveness in developing critical skillsets for multinational workforces will be assessed through formative evaluation. the program will rely on both interdisciplinary research faculty and development practitioners in three broad application areas: (1)

measures for alleviating poverty with data, algorithms, and ai applied to policy; (2) poverty interventions that integrate the natural and built environments in low-resource settings; and (3) improving health and wellbeing in low-income populations. dtod will also contribute to the development of shared public datasets aligned with national strategies and priorities related to advancing ai. the nsf research traineeship (nrt) program is designed to encourage the development and implementation of bold, new, potentially transformative models for stem graduate education training. the program is dedicated to effective training of stem graduate students in high-priority interdisciplinary or convergent research areas through comprehensive traineeship models that are innovative, evidence-based, and aligned with changing workforce and research needs. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: A Knowledge-Based Framework for Creating and Sustaining Transformational Change for Latinx Student Success in STEM

Awardee: University of Texas at El Paso

Amount: \$2,999,942.00

Abstract: this project aims to use a **\*\*diversity\*\***, equity, and inclusion lens to create systemic, transformational change at the university of texas at el paso to increase the number of latinx students, in particular latina students, who are competitive in stem careers. to achieve the aim of increased participation in stem fields at the national level, a cross-cutting and replicable institutional approach that considers learning outcomes, students' experiences, internal organizational structures, and external influences will be implemented. with support from the improving undergraduate stem education: hispanic-serving institutions program (hsi program), the project team will intentionally embed concern for **\*\*diversity\*\***, equity, and inclusion in teaching and learning, professional development, and policies and procedures, seeking to shift culture across the institution. a key aspect of the project to support long term impact is capacity building for research on the interplay between stem education and "servingness," a conceptual way to understand what it means to move from simply enrolling latinx students to actually serving them. the project seeks to institutionalize the systematic use of data and the authentic engagement of key stakeholders to build sustained change through continuous improvement and to maintain, sustain, and build upon inclusive infrastructure and resources. project personnel will identify, stratify, organize, present, and distribute data to be used for decision-making. a transformation team coordinated by the provost's office will use those data to recommend, plan, and evaluate action on relevant issues. the institution plans to transform stem undergraduate education through changes in core curricula that provide equitable opportunities to students. in a revitalization of the curriculum, working groups of faculty will develop modular materials for inclusion in the university core to increase inclusive instruction, stem

competencies, and engagement. the center for faculty leadership and development will implement a professional development series on inclusive and asset-based pedagogy. the administration will work to select, compensate, develop, and mentor future faculty leaders invested in \*\*diversity\*\*, equity, and inclusion. the provost's office will work with administration and the faculty senate to codify policies and procedures that recognize faculty and staff efforts in inclusive teaching and learning. the project will increase publications on metrics-based planning; promote regular use of metrics and research by deans, chairs, and program directors in planning and improving interventions; enhance the ability of stakeholders to understand multiple perspectives on data through visualization; and expand shared understanding of effective practices. changes will be institutionalized and sustained through policies and procedures that recognize and reward faculty and staff who focus on student success and servingness. the hsi program aims to enhance undergraduate stem education, broaden participation in stem, and build capacity at hsis. achieving these aims, given the diverse nature and context of the hsis, requires innovative approaches that incentivize institutional and community transformation and promote fundamental research (i) on engaged student learning, (ii) about what it takes to diversify and increase participation in stem effectively, and (iii) that improves our understanding of how to build institutional capacity at hsis. projects supported by the hsi program will also draw from these approaches to generate new knowledge on how to achieve these aims. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: NRT- FW-HTF: Linguistic diversity across the lifespan (LINDIV): transforming training to advance human-technology interaction

Awardee: Pennsylvania State Univ University Park

Amount: \$2,999,920.00

Abstract: technology such as smart voice assistants or computer-based intelligent tutoring systems has become crucial to people's private lives, education, and the workforce. this technology is largely based on standard american english and the misconception that there is a single, idealized variety of american english, which conflicts with the true **\*\*diversity\*\*** of language users. many u.s. speakers use a regional variety of american english, african american vernacular english, a signed language, a language other than english, or have some form of communication disorder. as the u.s. population is becoming older, age-related hearing loss and language impairments will also increase. the linguistic sophistication of technology has not kept pace with the growing linguistic **\*\*diversity\*\*** within the u.s. this technology is intended to improve the lives of humans and society at large, and people increasingly depend on it for access to governmental, community, health, and educational services, making the technology's current reliance on standard american english problematic. this national science foundation research traineeship award to the pennsylvania state university will educate a new generation of experts in human-technology interactions to address this issue. the project anticipates training 48 graduate students, including 23 funded trainees, from graduate programs in psychology, german, spanish, communication science and disorders, computer science and engineering, information sciences and technology, and learning design and technology. the comprehensive two-year traineeships will prepare trainees to address key challenges in human-technology interactions. improvements in human-technology interactions will help ensure the full participation of individuals with diverse language backgrounds, fostering an equal, diverse, and inclusive society. by applying integrated learning and transdisciplinary team science principles, trainees will be prepared to bridge the gap between language science and technology. trainees will also be prepared to think beyond disciplinary boundaries. this approach is considered optimal to prepare the next generation for the future of work. in a two-year program culminating in the new graduate certificate 'linguistic **\*\*diversity\*\*** and technology?', trainees will complete cross-disciplinary courses and professional development in language and technology. trainees will work on transdisciplinary team research projects that address tractable goal and produce clear products,

such as a design project, pilot application, or research study focused on integrating language science and human-technology interaction. trainees will also participate in seminars, research events, mentoring, and a linguistic **\*\*diversity\*\*** outreach program. they will complete the program with an internship with academic and private sector extramural partners to support careers bridging linguistics and technology, both inside and outside academia, in national and international settings. trained to work in diverse teams, trainees will be competent in creating knowledge and translating research outcomes into technological solutions that alleviate social, educational, and economic disparities for linguistically diverse populations. the nsf research traineeship (nrt) program is designed to encourage the development and implementation of bold, new potentially transformative models for stem graduate education training. the program is dedicated to effective training of stem graduate students in high priority interdisciplinary or convergent research areas through comprehensive traineeship models that are innovative, evidence-based, and aligned with changing workforce and research needs. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: URoL:EN Quantifying the phytochemical landscape through Indigenous Knowledge, interaction diversity, genomics, and network dynamics

Awardee: Board of Regents, NSHE, obo University of Nevada, Reno

Amount: \$2,999,552.00

Abstract: this project seeks to understand emerging network dynamics from global to molecular scales through convergent research that spans the most recent methodological advances in biology, chemistry, mathematics, anthropology, and traditional indigenous knowledge. the proposal specifically focuses on the effects of harvesting balsa wood from amazonian rainforests for wind-turbine production in china on forest bio**\*\*diversity\*\*** and indigenous communities. the main

objectives are to: 1) enhance knowledge of forest species ecological and chemical interactions through indigenous knowledge of bio\*\*diversity\*\* and medicinal plant value, 2) measure the effects of balsa-harvesting on these species interaction networks, and 3) use mathematical modeling to generalize these processes and make predictions about ecosystem resilience and sustainability. the project will be in collaboration with indigenous community members and will incorporate their traditional knowledge of plant and animal species as part of an integrated research team. this project directly increases our understanding of the rules of life by gaining insight into the genetic, chemical and ecological mechanisms at all scales of organization that maintain bio\*\*diversity\*\* in tropical systems and predicting the subsequent effects on ecosystem resilience in a changing environment. quantifying how phytochemical and genetic variation are jointly structured across the landscape and contribute to the maintenance of bio\*\*diversity\*\* can contribute substantially to understanding this rule of life: the resiliency of complex ecosystems can be predicted from carefully quantified genetics, ecological interactions, and disturbances, many of which are mediated through biochemical networks. the proposal specifically focuses on the effects of harvesting balsa wood for wind-turbine production in china from amazonian rainforests, and the research will examine the effects of forest disruptions on kichwa and waorani communities and on the phytochemistry and \*\*diversity\*\* associated with the tropical pepper shrub, piper. the proposed project will examine how these systems are linked across multiple scales, from global networks focused on producing sustainable energy, to networks of interactions with the indigenous peoples whose livelihoods and medicinal plant communities are affected by those production networks, to the ecological, chemical, and genetic networks that are the basis of species interactions with plant communities. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: FMRG: Eco: Future Eco Manufacturing of Recyclable Soft Electronics

Awardee: North Carolina State University

Amount: \$2,998,710.00

Abstract: this future manufacturing research grant (fmrg) ecomanufacturing project will enable eco manufacturing of recyclable soft electronics by seamlessly integrating a select group of biodegradable/recyclable materials and sustainable manufacturing processes, guided by economic and environmental life-cycle assessment. the rapidly increasing number of electronic devices that have decreasing lifetime in use pose three important challenges: (1) a huge amount of waste from used electronics, (2) rapid consumption of scarce elements, and (3) enormous energy consumption for manufacturing electronic devices. on the other hand, soft electronics is an emerging field. therefore, the team will develop new classes of soft electronics that are created from renewable materials using energy-efficient manufacturing processes, and that can either be degraded naturally or repurposed into high-value products after their lifetime. the project will bring together researchers in flexible/stretchable electronics, polymer chemistry, chemical and materials engineering, manufacturing engineering, sustainability, and science education. this interdisciplinary convergence project will provide a compelling basis to train a diverse cohort of future engineers and scientists. the education and workforce development efforts will include curriculum innovation, teacher professional development, outreach, and student internships, with a commitment to increasing the **\*\*diversity\*\*** in the workforce. this project is structured in five thrust areas addressing materials development, eco manufacturing, biodegradation/recycling, environmental and economic life-cycle assessment, and education and workforce development. more specifically, the project team will design reinforced cellulose composite as the substrate, new conjugated polymer as the semiconductor, composite with selected fillers as the dielectric, and silver nanowire network as the conductor. the research will address the challenges of developing high-performance materials that are renewable, biodegradable or recyclable. it will result in a viable all-printing-based manufacturing framework to enable the scalable fabrication of sustainable soft electronics. the scalability will be demonstrated with a laboratory-scale roll-to-roll system. the device components at their end of life will follow three

routes ? biodegradation (back to nature), recycling (back to manufacturing), or upcycling (converting to value-added new materials). the project will incorporate biodegradation and material circularity into the life-cycle assessment framework for soft electronics. this future manufacturing project is jointly funded by the divisions of civil, mechanical and manufacturing innovation (cmmi), electrical, communication, and cyber systems (eccs), and engineering education and centers (eec) in the directorate of engineering, and by the divisions of chemistry (che) and materials research (dmr) in the directorate for mathematical and physical sciences (mps). this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: NRT-URoL: Decoding the Mechanisms Underpinning Biofilm Function and Architecture in Extreme Environments

Awardee: Montana State University

Amount: \$2,984,140.00

Abstract: biofilms, communities of microorganisms attached to surfaces, occur in/on almost any environment and surface type. as a result, they have widespread impact on many aspects of both engineered and natural systems including agriculture, industry, and human health. extreme environments provide unique opportunities to conduct cross-cutting transformative science. their reduced bio\*\*diversity\*\* and extreme physical and chemical conditions enable detailed characterization and quantitative descriptions of important physical, chemical, and biological processes. this national research traineeship (nrt) award to montana state university (msu) will train a diverse group of ph.d. students to effectively engage and understand critical properties of extreme biofilm systems across multiple disciplines. the interdisciplinary research training will help to generate new insights that can control biofilms in engineered and natural systems. the integrative scientific training program uses innovative teaching elements that will equip participants with professional, communication, teamwork, research, and problem-solving skills that are broadly applicable across a variety of industrial and academic research careers. the project anticipates training 71 ph.d. students, including 21 nrt-funded trainees, with program activities also serving ph.d. and m.s. students across a range of stem departments. the nrt trainees will use life in extreme environments to push the boundaries of interdisciplinary research, integrating meta-omics-based approaches with high resolution imaging to understand intricate and cross-cutting interactions occurring in multi-species and multi-domain biofilms. students will investigate extreme biological systems that span the range of conditions where life survives, from the icy antarctic cryosphere, to yellowstone national park terrestrial hot springs, to the hydrothermal vents of guaymas basin in the gulf of california. major research themes include: (1) using metagenomics to examine genotypic variations and commonalities related to metabolic potential and \*\*diversity\*\* in extreme biofilm communities; (2) investigating patterns of biofilm composition and architecture using multi-scale microscopic imaging instrumentation; and (3) identifying patterns of extreme biofilm development, expression of novel pathways, and signaling molecules using proteomics and metabolomics. the

traineeship's project-based and collaborative science curriculum will help participants acquire the fundamental knowledge and skills necessary to converge across disciplinary boundaries to investigate the research themes, identifying properties and patterns of activity that explain biofilm cohesion and organization in extreme systems. key elements of this nrt program are scalable and sustainable, including (1) a program that allows students personalize their technical training, curriculum, and mentor team; (2) seminars, courses, and activities that help trainees develop transferrable professional and technical skills that feature strongly across a range of research-related careers, and (3) recruitment, mentoring, and retention strategies that broaden stem participation, foster mentoring and professional relationships, and improve students' research productivity. the program provides a holistic educational experience for the trainees, where innovative training elements thoughtfully prepare participants to thrive in a variety of research careers. the nsf research traineeship (nrt) program is designed to encourage the development and implementation of bold, new potentially transformative models for stem graduate education training. the program is dedicated to effective training of stem graduate students in high priority interdisciplinary or convergent research areas through comprehensive traineeship models that are innovative, evidence-based, and aligned with changing workforce and research needs. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: HSI Institutional Transformation Project: Cal Poly Pomona INtentional Venture Engaging STEM Students (CPP INVESTS)

Awardee: Cal Poly Pomona Foundation, Inc.

Amount: \$2,955,647.00

Abstract: with support from the improving undergraduate stem education: hispanic-serving institutions (hsi program), this track 3 itp project at california state polytechnic university, pomona

(cpp) will advance the goals of the hsi program by embedding high-impact practices (hips) during three critical transitions in the stem student life cycle: (1) secondary to post-secondary education -- scale first year experience (fye) courses and course-based undergraduate research experiences (cures), and embed peer learning assistants (plas) in fyes; (2) lower division to upper division stem courses -- embed cures in second year stem gateway courses and capstone and upper-division ge courses; (3) graduation into the stem workforce -- utilize two innovative components: "micro" internships and alternative learning records (alrs). the project will scale the number of stem students participating in internships by embedding six-week "micro" internship experiences in junior gateway and senior capstone courses. the project will develop and implement two alrs -- leadership and research career development. to support stem faculty, the project will provide stem faculty institutes to coach faculty in developing culturally relevant pedagogy anchored in **diversity**, equity, and inclusion, developing fye courses, embedding cures, micro-internships, and alrs in their courses and programs. the specific aim of the project is to contribute to the understanding of how to build institutional capacity to enhance the quality of undergraduate stem education at hsis. the program evaluation plan will focus on institutional-level variables including recruitment, retention, and graduation rates of stem students in the project by utilizing both formative and summative assessment methods. this project will employ quasi-experimental design to examine the impact of plas on the sense of belonging and academic self-efficacy of first year students in fye courses. it will use mixed-methods to examine both the impact of micro-internships and alrs on the professional identities of stem students and the impact of the faculty professional development efforts, including pre-post surveys, interviews, and focused group discussions. the project will generate new knowledge and contribute to the development of the nascent research on the impact of alrs and course-embedded micro-internships on stem student success. the broader impact of the project is the potential to develop and test a model that will be disseminated to and can be utilized by the california state university system which serves the greatest number of hispanics and underserved stem students in the nation, and other institutions that serve large populations of students who are

urms, first-generation and low-income. the hsi program aims to enhance undergraduate stem education, broaden participation in stem, and build capacity at hsis. achieving these aims, given the diverse nature and context of the hsis, requires innovative approaches that incentivize institutional and community transformation and promote fundamental research (i) on engaged student learning, (ii) about what it takes to diversify and increase participation in stem effectively, and (iii) that improves our understanding of how to build institutional capacity at hsis. projects supported by the hsi program will also draw from these approaches to generate new knowledge on how to achieve these aims. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: SCC-IRG Track 1: Fostering Smart and Sustainable Travel through Engaged Communities using Integrated Multidimensional Information-Based Solutions

Awardee: Georgia Tech Research Corporation

Amount: \$2,548,000.00

Abstract: this smart and connected communities award supports research that will develop systematic deployment tools that smart and connected communities can use to achieve their sustainable travel goals in a quantifiable manner by leveraging advances in information, communication and sensor technologies. while the deployment of advanced technological solutions offers great promise for communities to improve residents' quality of life and prosperity, they are faced with significant challenges in realizing these aspirations due to the **\*\*diversity\*\*** in technological and travel needs and barriers faced by the residents. solutions to achieve sustainability objectives related to enhancing travel mobility, safety, equity, and access will be developed using the city of peachtree corners (ga) as an immersive living lab. they include building novel partnerships involving emerging micromobility services in the private sector and the well-established public transit modes. further, they will involve personalized behavioral interventions

to nudge and incentivize personal auto users to consider sustainable alternatives through seamless information provision. at the community level, public policy interventions will seek to enable flexible and novel travel alternatives while ensuring that all residents have access to timely travel-related information. for underserved and underrepresented residents, the solutions will include strategies to overcome information deserts in lower-income neighborhoods, age-related technology savviness issues for senior residents, and reduced access to smartphones and transportation options. these solutions will be developed using data collected from community residents and other sources, and deployed using an information design system that provides targeted information delivery to the various stakeholders in the community using multiple delivery mechanisms, including a community app. this project will advance theory and deployment paradigms associated with holistic, community-level decision-making to achieve travel sustainability goals characterized by multiple, disparate objectives while meeting the needs and constraints of different stakeholders. in particular, it will address the challenges of how to integrate disparate, multi-source data from various stakeholders and use it to systematically generate multidimensional solution options (partnerships, behavioral interventions, policy interventions) to meet multiple sustainability objectives at the community level in a systematic, quantifiable manner over time. it will draw on methods from multi-objective and multi-agent optimization, machine learning, behavioral economics, and data and policy analytics, to generate the multidimensional solutions. further, it will lead to novel paradigms and algorithms for the solution options themselves, and for the development of generalizable principles related to practical deployment frameworks in the inherently complex, multidimensional smart and connected communities. the project will also develop formal methods for information design and delivery that translate the multidimensional solutions into actionable information that is seamless for the various stakeholders. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Co-Development of Telehealth, Remote Patient Monitoring, and AI-based Tools for Inclusive Technology-Facilitated Healthcare Work of the Future

Awardee: New York University

Amount: \$2,515,999.00

Abstract: as the use of digital health technologies grows, gaps between the potential of new technologies, existing healthcare practices, and workers' preparedness for new technologies limit the potential of digital health to achieve acceptance and effective utilization at scale. this transition to scale research project views inclusion as a key driver of scale in future technology-facilitated healthcare work. inclusive technology for healthcare work will enable workers in diverse roles and skills to leverage increasing access to data-driven technologies. the project focuses on the growth of data-intensive technologies (dit), which include telehealth and ai-based tools. the project's approach to transition to scale centers on alleviating existing misalignment between current healthcare work and data-intensive technologies in three ways. first is through the co-development of tools and generalizable design principles with users that lower the barrier to technology integration for healthcare workers. second is by empowering individuals within healthcare systems who have diverse roles to adopt and use the tools and improve their skills. third is to enable patient-centered healthcare that promotes autonomy and strengthens clinician-patient concordance. the project represents a multi-institutional commitment to transitioning innovative healthcare to scale, through dit facilitated inclusion of diverse workers in healthcare systems across the u.s., which together encompass over 1000 care sites in u.s. 24 states, multiple work roles, and different levels of training and hierarchy. this project brings together several scientific fields, including human-computer interaction, health informatics, artificial intelligence (ai), sensing, medicine, organizational behavior, and research on **diversity** and inclusion. the investigator team is structured to achieve multiple convergent goals such as quantifying the impacts of scaling dit on inclusive healthcare work and modelling prescription and adoption of dit towards inclusive

deployment at scale. additionally, the investigators seek to identify generalizable dit design principles for inclusive healthcare work at scale, and to develop theory and tools to facilitate at-scale inclusion through dit-based patient-provider concordance. finally, the project expects to develop tools and practices for lowering barriers to comprehension of and engagement with dit by diverse healthcare workers; to create ai-based team-focused tools; and to analyze the opportunities and challenges in using ai for diverse healthcare teams? work. this project has been funded by the nsf future of work at the human-technology frontier cross-directorate program to promote deeper basic understanding of the interdependent human-technology partnership in work contexts by advancing design of intelligent work technologies that operate in harmony with human workers. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: MIM: Using Machine Learning and a Model Watershed to Understand how Microbes Govern Food Web Architecture and Efficiency

Awardee: University of Hawaii

Amount: \$2,499,432.00

Abstract: rules that govern food web dynamics, which describe how energy is transferred among different living organisms, are among the most universal laws of nature. consumption up a food-chain is an inherently inefficient process that leads to significant and predictable losses through waste and respiration. this rule of life can be leveraged to model how biological **\*\*diversity\*\*** will respond to phenomena such as sudden changes in the environment or species extinctions, and is an important constraint in food production. until now, food web research has largely focused on the interactions among plants and animals, however, microbes living in and on larger organisms play essential roles in their health, rates of reproduction, and ability to digest food. this project will examine how symbiotic microbes govern the efficiency of food webs, and how aspects of food webs,

in turn, determine the composition of symbiotic microbes. the predictive insight gained from this research may make it possible to manipulate the composition of microbes to create more efficient food webs that can potentially guide restoration of degraded habitats, capture carbon, and increase yield in agriculture, aquaculture and biofuels systems. in addition, workforce development and outreach to under-represented groups including native hawaiians and pacific islanders, will be performed. postdoctoral researchers, graduate students and undergraduates will be trained in microbiome science through research experiences and class modules. this proposal addresses the hypothesis that canonical laws governing the transfer of energy among trophic levels of food webs both constrain, and are constrained by the composition and function of microbiomes. leveraging a model hawaiian watershed system, this project aims to understand how host-associated microbiomes govern food chain efficiency and how, in turn, trophic position within a food web affects the microbiome. the project will develop transfer learning approaches based on machine-learning tools trained on higher-feature datasets (such as the earth microbiome project) to enable robust predictions of the interaction between food chain length, trophic position and microbiome **diversity**. two tractable experimental systems will be used to explore these predictions. the first is a simple four-tiered bromeliad food web mesocosm where the number and of trophic levels is controlled. the second consists of a three-tiered mosquito microcosm in which all microbial symbionts are isolated and manipulated. associated genomic data will enable a mechanistic understanding of how microbiomes influence food web efficiency and function by altering metabolic capacity of hosts. in summary, this project will employ food web theory to explain and predict the interactions between the microbiome, the host, and the environment. this project is jointly funded by the understanding rules of life: microbiome interactions and mechanisms program and the established program to stimulate competitive research (epscor). this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Engaging Multicultural Audiences through Inclusive STEM content on YouTube

Awardee: PBS FOUNDATION

Amount: \$2,499,320.00

Abstract: this innovations in development project is funded by the advancing informal stem learning (aisl) program, which seeks to (a) advance new approaches to and evidence-based understanding of the design and development of stem learning in informal environments; (b) provide multiple pathways for broadening access to and engagement in stem learning experiences; (c) advance innovative research on and assessment of stem learning in informal environments; and (d) engage the public of all ages in learning stem in informal environments increasing greater **\*\*diversity\*\***, equity, and inclusion in science not only presents a social justice goal, but is also vital to the financial and social success of the nation. the stereotype of the older white male scientist has obscured the contributions of women and people of color. this project seeks to remedy these perceptions which are barriers to entry into stem fields. the project will create a large-scale hub for stem themed video content on youtube and other social media platforms, featuring 100+ original stem videos produced by pbs partners. this hub and accompanying research seeks to identify the characteristics of online stem content that attract (or fail to attract) underrepresented groups, specifically black and hispanic communities as well as women of all races. the objectives of this project are to 1) provide a unified online science-themed hub, pbs terra, on youtube and other platforms for hosting, sharing, and distributing digital stem series from diverse producers from across the pbs system; 2) conduct surveys and focus groups to examine and understand the needs and expectations of women, black and hispanic communities and their consumption of stem video content online and 3) test hypotheses about the communicative strategies of stem videos that feature black and hispanic female scientists. project collaborators include pbs, researchers at the university of utah and the university of georgia, and consultants and advisors with expertise in broadening participation and inclusion in stem. little is known about how or why adult americans

seek science content on youtube, especially the motivations of adults from underrepresented minorities and females. the key research questions in this project are: 1) why do black and hispanic audiences and women of all races seek science video content online? 2) how does showing black and hispanic female scientists in science video content on youtube impact viewers? identification with and sense of belonging in stem? 3) how does the use of humor by black and hispanic scientists in youtube science content affect viewers? perceptions of the communicator and their engagement with stem content? 4) how does the appearance and manner of dress of black and hispanic scientists in youtube science content affect viewers? perceptions in the aforementioned areas? a nationally representative baseline survey will be conducted. a probability sample of 2000 respondents will be obtained including oversampling of black and hispanic audiences. to complement findings from the survey, focus groups will be conducted in eight different regions of the country to learn why these targeted audiences do or do not seek science content on youtube and what motivates them to share the content with their social media network. in addition, an experiment embedded in an online survey will test the hypothesis that greater on-screen representation of women and scientists of color will broaden existing perceptions about scientists. the experiment will consist of a 3 (scientist's race: black/hispanic/white)  $\times$  2 (science issue: controversial/non-controversial)  $\times$  2 (style: casual/professional) between-subjects design. survey participants will be randomly assigned to the experimental conditions. these factors (science issue and host appearance) can be altered by content producers to better reach and engage the targeted audiences. the project not only investigates theoretical questions at the intersection of stem stereotypes and race, but findings related to these experimental conditions will offer practical insight into strategies that can be used by science communication practitioners. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: NSF INCLUDES Alliance: Broadening Career Pathways in Food, Energy, and Water Systems with and within Native American Communities (Native FEWS Alliance)

Awardee: University of Arizona

Amount: \$2,493,961.00

Abstract: the native FEWS (food, energy, water systems) alliance is focused on innovative research and community partnerships linking two interconnected challenges: a crisis in access to food, energy, and water in indigenous communities; and limited educational and career pathways available to indigenous populations to address these needs. the disproportionate number of indigenous people who have been negatively impacted by climate change, the on-going covid-19 pandemic, and pollution on tribal lands demonstrate the urgent need for effective solutions. currently, there are limited institutional pathways for native americans and other underrepresented students to pursue environmental careers. the university of california at berkeley, university of arizona and american indian higher education consortium will work with over 20 partners to significantly broaden the opportunities for participation and the ecosystem of research and practice training by and for native americans and other underrepresented student groups. a focus will be on students who possess, and those who seek, the necessary training and preparation to address these critical challenges. through the application of culturally-relevant approaches (successfully developed and evaluated by partners at all levels of the educational continuum), the alliance will develop curricula and mentoring guides, offer workshops, adapt and adopt best practices, and share results. these activities will enable institutions across the country to access native FEWS educational and mentoring materials. broadening participation will produce greater **\*\*diversity\*\*** of thought and generate culturally relevant sustainable solutions that are applicable to local communities yet can be used as a basis for applications more broadly. mainstream science and technology programs have to date been ineffective in responding to indigenous challenges at the nexus of food, energy, water systems (FEWS), and do not adequately serve or engage indigenous communities. the result is a deepening of social alienation and professional marginalization of indigenous youth. the native FEWS

alliance will integrate place-based approaches to teaching and **\*\*diversity\*\*** with applied research and indigenous knowledges to transform fews education to be more relevant to indigenous communities. the implementation plan is designed to produce more successful recruitment, matriculation, retention, and degree attainment outcomes. by bringing together the resources, expertise and experiences of multiple educational institutions and stakeholders who all share a proven track record in widening pathways for indigenous students, the alliance will develop a networked improvement community to achieve the following interrelated goals: address urgent fews challenges in indigenous communities; co-develop integrated, indigenous, place-based fews curricula, mentoring, and practice experiences; transform institutional science and technology fields to be relevant and accessible to indigenous communities; and recruit, retain and graduate indigenous students to pursue higher education and careers in fews and bring their knowledge back to their communities. alliance initiatives will be rigorously evaluated and disseminated, contributing new knowledge to the research base of effective practices in recruiting, teaching, and mentoring native american students and professionals, and in building ethical, effective co-designed partnerships. the forms of dissemination will include publications, case studies, curricula, guidebooks, webinars, podcasts and multimedia resources for indigenous stakeholders and to educate the wider sustainability science communities. this nsf includes alliance is funded by nsf inclusion across the nation of communities of learners of underrepresented discoverers in engineering and science (nsf includes), a comprehensive national initiative to enhance u.s. leadership in discoveries and innovations by focusing on **\*\*diversity\*\***, inclusion and broadening participation in stem at scale and co-funded by the directorate for biological sciences, division of biological infrastructure, and the division of environmental biology. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Graduate Research Fellowship Program (GRFP)

Awardee: Joan and Sanford I. Weill Medical College of Cornell University

Amount: \$2,446,750.00

Abstract: the national science foundation (nsf) graduate research fellowship program (grfp) is a highly competitive, federal fellowship program. grfp helps ensure the vitality and \*\*diversity\*\* of the scientific and engineering workforce of the united states. the program recognizes and supports outstanding graduate students who are pursuing research-based master's and doctoral degrees in science, technology, engineering, and mathematics (stem) and in stem education. the grfp provides three years of financial support for the graduate education of individuals who have demonstrated their potential for significant research achievements in stem and stem education. this award supports the nsf graduate fellows pursuing graduate education at this grfp institution. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: CyberCorps Scholarship for Service (Renewal): Promoting Cybersecurity Excellence and Diversity via Dynamic and Applied Learning Tactics

Awardee: University Enterprises Corporation at CSUSB

Amount: \$2,432,950.00

Abstract: this project supports continuation of the cybercorps®: scholarship for service (sfs) program at california state university, san bernardino (csusb). the csusb program promotes cybersecurity excellence through a dynamic curriculum, unique applied learning requirements, and a diverse student population. students work on a curriculum designed around the needs of government organizations seeking well-qualified cybersecurity personnel. the program provides training options for many in-demand skills within the federal government and encompasses four bachelor?s and five master?s degree programs. a typical csusb cybercorps® student is well-versed in cybersecurity

policy, tactics, threat analysis, counterintelligence, networking, database, offensive and defensive hacking, penetration testing, and forensics, including with applied professional experiences. csusb's service area is richly populated with residents from diverse ethnic backgrounds, including those groups that are currently underrepresented in the cybersecurity field. in addition, most students are first generation minority students, transferring from community colleges, often from low-income and disadvantaged backgrounds. from tutoring to etiquette to professional behavior, csusb places great emphasis on ensuring this diverse student cohort (50% hispanic and 43% female) learns the skills necessary to successfully obtain and retain professional employment. the csusb sfs program also mentors other institutions regarding best practices in recruitment **\*\*diversity\*\***, placement strategies, leveraging university resources, and program management. csusb's cybercorps® program will continue as a source of high-quality cybersecurity workforce personnel with three project objectives. first, the program will train four cohorts of graduate and undergraduate students from diverse backgrounds. second, the project team will provide ongoing academic support and mentoring to the scholars with the goal of a 100% annual retention rate (barring extenuating circumstances). last, the program aims to place all scholarship recipients in federal, state, local, or tribal cyber service positions, with at least 80% in federal executive branch positions. the program's components and its effectiveness will contribute to the body of knowledge and best practice strategies for successful recruitment, mentorship, retention, and placement of cybersecurity professionals. under the mentorship of experienced faculty and professionals, cybercorps® students are required to work in applied activities beyond the classroom including competitions, research, and community outreach. the csusb program is also pursuing unconventional approaches to showcase student talents from game development and outreach to challenging technical projects, creating a nationally recognized cybersecurity program. this project is supported by the cybercorps® scholarship for service (sfs) program, which funds proposals establishing or continuing scholarship programs in cybersecurity and aligns with the u.s. national cyber strategy to develop a superior cybersecurity workforce. following graduation, scholarship recipients are required to work in cybersecurity for a federal, state,

local, or tribal government organization for the same duration as their scholarship support. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

-----  
Title: MIM: A thermodynamic theory of microbiome assembly, adaptation and evolution evaluated using modular microbial environments

Awardee: University of California-Berkeley

Amount: \$2,400,000.00

Abstract: across earth's ecosystems, microbes adapt and form communities (microbiomes) across gradients of energy and resource richness. like the machines and electrical circuits we engineer, power and efficiency are key features that also determine the competitiveness of microbes in communities. over evolutionary time, microbes have optimized their own molecular machines to convert available energy with high efficiency, minimizing the loss of waste energy as heat. microbes have a range of strategies, reflecting the balance between the rate of new cell production (power), and its efficiency (yield), while also dealing with various costs of survival that reduce yield. this research project will test the hypothesis that microbiomes, assemble from individual members to form communities that also optimize power while increasing efficiency. this principle of power and efficiency optimization may apply generally across different levels of biological organization from proteins to ecosystems. researchers will study microbiomes from soils and the human gut as model systems to test this idea. they will develop a new experimental platform, involving multiple compartments to control how microbiomes interact, with integrated nanotechnology sensors to measure microbial efficiency as heat output, plus advanced microscopy to measure yield as microbes grow. this work will test if information stored in microbial genomes can predict their power-yield strategies, and if aspects of microbiome **\*\*diversity\*\*** can be related to efficiency, developing a predictive modeling framework. if this fundamental thermodynamic theory can explain

patterns in biological organization from cells to communities, it will provide an important new framework to predict how biology will respond to future conditions on earth. broader impacts include involving community college students in the research, in addition to graduate and postdoctoral students. outreach activities consist of developing scientific videos for a storytelling platform, which would be available to the general public.

microbes, like all living organisms, maintain the order of life through the creation of entropy. they exist in open, non-equilibrium thermodynamic systems, across gradients of free-energy that fuel the formation and maintenance of structures (proteins, cells, communities) that enhance exergy flow, while attempting to minimize dissipation of waste heat ? enhancing overall entropy production in the process. the assembly and succession of microbial communities are driven by flows of exergy, and it is the trade-off between maximum power and minimum heat dissipation that regulate yield (i.e. efficiency). this trade-off towards the production of entropy is a fundamental thermodynamic principle. as a biological optimization function, the optimization of power and yield aligns thermodynamics and evolution through natural selection, in that constraints such as resource availability or stress, modulate the fitness of an organism depending on the placement of their power:yield strategy across a pareto optimal curve. how these trade-offs manifest at the community scale has not been empirically tested. this research will test this by (1) developing a novel integrated nanocalorimetry-microfluidics platform to control gradients of resources and stress, simultaneously quantifying power, yield and entropy production in an open system; (2) performing a series of manipulative experiments to evaluate how properties of microorganisms and microbiomes relate to power, yield and entropy production and bio(geo)chemical outputs, and (3) develop simulation tools based on the thermodynamics of power-yield trade-offs to predict the emergence of microbiome function and composition. this thermodynamic theory is applicable to all living organisms, with the outcomes being generalizable beyond microbiome sciences.

co-funding for this award was provided by the division of materials research. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: FRHTTP: Center for Quantum Information and Control

Awardee: University of New Mexico

Amount: \$2,400,000.00

Abstract: quantum information science (qis) is an interdisciplinary field at the interface of two of the greatest scientific and technical triumphs of the 20th century: quantum physics and information science. the digital revolution that followed, based on semiconductor chips, laser communications, and computer science, has fueled the economic engine of today's information society. qis will fuel a second quantum revolution into the 21st century. the second quantum revolution will harness the full power of quantum mechanics (the physics of the atomic world) with devices that rely on quantum-weird phenomena such as superposition and entanglement to process information in ways that are much more powerful than today's best supercomputers and cybersecurity systems. the focused research hub in theoretical physics (frhttp): center for quantum information and control (cqic) funded in this grant from the nsf will create a "theory hub" for fundamental research that provides the foundation for the second quantum revolution. housed at the university of new mexico (unm), cqic brings together an interdisciplinary team of theoreticians with expertise in physics, computer science, electrical engineering, and chemistry, as well as partners at sandia national laboratories, los alamos national laboratory, and honeywell quantum solutions, to collaborate, innovate, and tackle the most important outstanding problems in qis. cqic will provide a focal point for united states qis-theory community to retain its competitive advantage. cqic will serve the national quantum initiative (nqi) act by hosting focused workshops that target common problems, share lessons learned, and help to break logjams when they arise to push forward the goals of the nqi. the hub will be critical for education and training, with a focus on building a diverse and inclusive next-generation qis workforce. to achieve these goals, cqic will administer a prize postdoctoral fellowship program, host seminars, workshops, conferences, and a visitor's program,

and critically focus on synergistic research that brings together the principal investigators at unmc with its partnering institutions. the research will be anchored in tackling four "big questions" in contemporary qis: i. what is the computational power of quantum matter? ii. how do we efficiently represent quantum systems, and when do these representations lead to efficient classical algorithms? iii. what quantum advantage can be achieved with noisy intermediate-scale quantum (nisq) devices? iv. what near-term quantum algorithms and architectures can yield practical results?

postdoctoral fellows will provide the "connective tissue," creating bridges between senior participants and bringing additional expertise to the center. cqic's intensely collaborative environment will provide the necessary incubator for the qis-theory community to work together to tackle the big questions. in addition, cqic will host a variety of hub activities that will bring together the community to interact, create, and tackle critical problems, and integrate this with education, training, and shared educational resources to help develop the next generation of quantum information scientists. hub activities include the long-running squint annual workshop, with a 25-year history of focus on building community for early-career scientists at a world-class conference. cqic will create outreach programs that focus on building "diversity" and inclusion of traditionally underrepresented groups in qis. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: FMRG: Eco: Process-Structure-Property Relationships of 3D Printed Earth Materials and Structures

Awardee: Columbia University

Amount: \$2,390,040.00

Abstract: this future manufacturing research grant (fmrgecomanufacturing project will comprehensively characterize optimal mix designs for 3d printed earth materials and structures,

linking microstructural development and soil science with material and structural property characterization and optimization of 3d printing methods. earth materials are an emerging, sustainable alternative to cementitious materials because of their low embodied carbon, affordability, safety, and thermal characteristics. by using minimally processed materials and sourcing raw materials from the construction site, 3d-printed earth structures could substantially reduce transportation, chemical treatments, excess manufacturing, warehouse storage, and intermediary storages that are inextricably intertwined with cementitious materials. using a range of bacterial and biopolymer binding agents, as well as bio-based fibers and nano-fibers reinforcing additives, this project will characterize printable mixtures of earth- and bio-based building materials?modernized versions of ancient technologies?as a critical step for climate-friendly digital manufacturing of the built environment. in addition to creating new scientific knowledge for additive manufacturing using nonconventional materials, this project supports education and **\*\*diversity\*\*** by developing a graduate earth-based technology course and an extracurricular experience for students from marginalized communities that includes hands-on materials assessment, digital fabrication of an earth-based shelter, and community activities. through a comprehensive series of optimized mix design development, fresh- and hardened-state properties characterization will produce an effective and sustainable framework for improved shape stability and interlayer properties of the final printed earth structures. the proposed research links, for the first time, the following multi-scale investigations to advance the science and engineering of 3d printed earth materials and structures: (1) establishing the soil characterization and microstructural design methodologies of 3d printable earth mixtures, (2) elucidating the process-structure relationships of 3d printed earth materials and the effects of additives, including a range of biomineralizing microbes and biopolymers, on fresh-state properties, (3) characterizing the hardened-state properties with a focus on alternatives to stabilization, and (4) advancing the processing science of small- and large-scale 3d printed earthen structures. this research and educational effort will contribute to a broader interdisciplinary scope on quantitative and qualitative expertise related to the automated construction, mechanical,

thermal, and environmental impacts of earth materials, a critical future in low-carbon and affordable buildings. this future manufacturing project is jointly funded by the divisions of civil, mechanical and manufacturing innovation (cmmi), engineering education and centers (eec), and industrial innovation and partnerships (iip) in the directorate of engineering, and by the division of materials research (dmr) in the directorate for mathematical and physical sciences (mps). this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: IMPACTS OF RAPID LANDSCAPE CHANGE AND BIODIVERSITY ON VIRUS HOST SPECIFICITY

Awardee: University of California-Davis

Amount: \$2,379,565.00

Abstract: rapid changes to landscapes and the bio\*\*diversity\*\* of plants and animals are altering relationships between microbes and their natural hosts with direct implications for human health. this study investigates the impacts of deforestation, landscape change, and bio\*\*diversity\*\* on virus characteristics that determine zoonotic potential, including virus ?host plasticity?, which is the \*\*diversity\*\* of host species a virus can infect in nature. previous work has indicated that higher virus host plasticity is linked to increased likelihood of human-to-human transmission and wider geographic spread. this project seeks to understand whether landscape and bio\*\*diversity\*\* change drive microbes towards greater host plasticity and therefore heightened pandemic risk. findings from this research will contribute to ecological theory on the impact of environmental changes on microbial adaptation, with practical implications for management of ecosystems at high risk for pathogen spillover. this research is especially relevant to public authorities seeking evidence on the relationship between environmental change, bio\*\*diversity\*\*, disease outbreaks, and pandemics. training opportunities provided through this project will help foster a network of cross-trained

scientists interested in disease dynamics, public health and animal health who will strengthen one health research into the future. Viruses have more opportunities to adapt to new hosts at the edge of ecosystem boundaries, which could influence virus host plasticity and increase spillover risk as new ecosystem edges are formed through habitat fragmentation. To test this hypothesis, this research investigates the host range of bat-borne coronaviruses and mosquito-borne arboviruses (flaviviruses, alphaviruses and bunyaviruses) across replicated gradients of landscape change and community composition in the biodiverse tropical forests of Southeast Asia. Theoretical and computational modeling, underpinned by field investigations and in vitro experiments, will evaluate (1) how virus host and vector plasticity changes at the edge of ecosystems, such as at the boundary between forest and urban habitats, (2) how virus host plasticity is related to virus epidemiology across landscapes, and (3) how intra-host genetic **diversity** of viruses is influenced by host and vector plasticity. Data and model driven insights will inform on the role that mosquito vectors play in constraining or expanding virus host plasticity and genetic **diversity**. Characterization of bat-borne coronaviruses and host affinities in an ecosystem with SARS-CoV-related viruses will further inform on coronavirus evolution and emergence of zoonotic potential. This study explores an important paradigm of functional relationships between **bio**diversity**** and public health to advance a mechanistic understanding of zoonotic virus emergence with potential to be generalized to other systems. This award reflects NSF's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: IntBIO: Integrative Demography: Combining Ecology, Remote Sensing, and Genomics to Understand Population Dynamics

Awardee: University of California-Davis

Amount: \$2,372,311.00

Abstract: **bio**diversity**** is critical for the health of ecosystems, our biosphere, and humankind.

however, bio\*\*diversity\*\* is threatened by habitat loss and climate change. habitat loss and climate change have resulted in the acceleration of species extinctions across the world. within species, the extinction or persistence of populations determines whether a species will survive at all. thus, understanding the factors that contribute to population persistence or extinction is critical for predicting future population dynamics and managing bio\*\*diversity\*\* in a changing world. population persistence is determined by genetic composition, ecological habitat, environmental stresses, and interactions among these factors. this award will integrate advances in genomics, remote sensing, and statistical modelling to develop new predictive models of population persistence and extinction. the models created in this project will be critical for understanding population dynamics, predicting responses to future change, and providing tools to direct the implementation of genetically-informed conservation strategies. the project also includes an educational component that will provide research and training opportunities for a new generation of biologists to prepare them to incorporate integrative approaches to understand complex aspects of climate change and its effect on biological systems. training the next generation of biologists to be able to integrate across fields is vital to addressing the complex impacts of climate change. to achieve this, graduate level workshops in field ecology, remote sensing, genomic data analysis, demographic modeling, and science communication and professionalism will be developed and taught. to help build an inclusive stem pipeline, an integrative course based undergraduate research experience (cure) for freshmen will be developed, and the project will support master's students for summer research as part of the advancing \*\*diversity\*\* to educate the professors of tomorrow (adept) program. the ability to predict how the genetic composition of populations impacts their long-term persistence or extinction in different and changing environments requires integrating analysis techniques and data across diverse fields. evolutionary genomics can identify past targets of selection and current determinants of fitness, but has not been effectively integrated with demography to explain multi-generation population dynamics. conversely, demographic modeling can determine which aspects of organismal establishment, growth, survival, and reproduction (life history) are most critical for

population growth or decline, but does not usually consider genomic determinants of these fitness components. *Streptanthus tortuosus* (mountain jewelflower) will be used for this research. *S. tortuosus* is an ideal species for this research due to its sensitivity to climate, variation within and among populations in traits and life history timing, and demographic and genomic tools currently in development. This project will: 1) use genomics to quantify genetic variation among individuals; 2) apply spectral remote sensing to understand the impact of stressors, the environment, and genotype on plant physiology and growth; and, 3) develop a statistical and demographic modeling framework to integrate these measures to understand and predict the factors underlying population persistence or extinction. While past research has investigated these components individually and some interactions among them, this award explores whether population dynamics is an emergent property that can be best understood by developing new demographic models that integrate all of these inputs. Together, understanding how **diversity** in genes, traits, physiology, and environment scales to impact individual performance and population dynamics will provide critical new insights into the ecological and evolutionary processes driving persistence or extinction. The resulting integrative demography models will provide a road map for conservation biologists and managers to use genomic information to predict effects of different conservation strategies, such as assisted migration or introducing genetic variation, which can be applied across wild, managed, and agricultural populations. This award reflects NSF's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Expanding a Model for Interactive Social Science Exhibits Presented in Outdoor Public Spaces

Awardee: Exploratorium

Amount: \$2,359,010.00

Abstract: Public outdoor spaces present opportunities for social experiences and learning. This

broader implementation project will expand and evaluate a model that transforms urban public spaces into accessible and engaging environments for learning social science in outdoor public spaces. the model combines social science inquiry exhibits, place making and human facilitation of learning experiences in outdoor public areas. project exhibits use the facilitated social interactions as both the content of and medium for the experiences. this project will adapt the existing exhibits and add new exhibits and facilitation techniques for testing in three different urban environments. project research will explore the efficacy of these adaptations and revised facilitation techniques for the different settings in collaboration with civic partners at each site. the project will share the model and research findings widely through the exploratorium website and publications for researchers, developers, and educators. the team's prior research showed that facilitators improved multiple learning outcomes with the current exhibits. visitors acquired new social observation skills, reflected on their own experiences, perceptions, and actions, and increased their awareness for how social behavior, cognition, and emotion can be studied scientifically. building on the prior research, the project will install the exhibition and test its efficacy in three different urban environments and explore the adaptations that are required for different settings with different civic partners. the project will use design-based research to develop a new theoretical model of facilitation strategies for supporting science learning in outdoor public spaces. for evaluation, the project will use mixed methods, including observations, interviews, surveys, and document review. evaluation will assess success in attracting and engaging visitors; conveying social science concepts; prompting self-reflection of judgments and actions; and fostering empathy among those with different social identities. the project will assess the extent to which participants, particularly those from marginalized communities, experience feelings of belonging and inclusion. the project will be presented in three sites which represent the significant \*\*diversity\*\*, income levels, and urban environments of san francisco. facilitation strategies are being co-developed with urban alchemy, an organization that works within distressed urban communities in san francisco. project site partners and collaborators include the san francisco public library, the port of san francisco, and the san

francisco department of parks and recreation. the project will also measure partnership outcomes, through surveys and interviews, to look at the extent and ways the project integrates a co-creation model and develops an authentic, mutually beneficial, sustainable partnership. the project will generate and disseminate generalizable knowledge about the affordances of combining informal science learning, placemaking, and facilitation in a variety of free, outdoor stem learning spaces in collaboration with local community groups. the project will also advance public understanding of the social and behavioral sciences. this research project is funded by the advancing informal stem learning (aisl) program, which seeks to (a) advance new approaches to and evidence-based understanding of the design and development of stem learning in informal environments; (b) provide multiple pathways for broadening access to and engagement in stem learning experiences; (c) advance innovative research on and assessment of stem learning in informal environments; and (d) engage the public of all ages in learning stem in informal environments. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Graduate Research Fellowship Program (GRFP)

Awardee: University of Connecticut

Amount: \$2,357,733.00

Abstract: the national science foundation (nsf) graduate research fellowship program (grfp) is a highly competitive, federal fellowship program. grfp helps ensure the vitality and **\*\*diversity\*\*** of the scientific and engineering workforce of the united states. the program recognizes and supports outstanding graduate students who are pursuing research-based master's and doctoral degrees in science, technology, engineering, and mathematics (stem) and in stem education. the grfp provides three years of financial support for the graduate education of individuals who have demonstrated their potential for significant research achievements in stem and stem education. this award supports the nsf graduate fellows pursuing graduate education at this grfp institution. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: NRT-QL: A Program for Training a Quantum Workforce

Awardee: Colorado School of Mines

Amount: \$2,344,084.00

Abstract: recent progress in quantum information science and technology (qist) promises advances that will fundamentally reshape today's leading technologies, including computing, communications, and sensing. a well-prepared workforce is essential to fulfilling this promise. in response to this critical workforce need, this national science foundation research traineeship (nrt) award to the colorado school of mines (mines) and san jose state university (sjsu) supports the development of rigorous, integrated, interdisciplinary training programs preparing both master's and doctoral students for careers in qist. the program has three components that address key challenges in training a quantum workforce. first, new training materials will be developed to introduce qist basics to students from different disciplines. trainees will come from physics, electrical engineering, metallurgical and materials engineering, applied mathematics and statistics, computer science, and quantum engineering. second, industrial and national lab partners will be engaged to provide trainees access to cutting-edge technologies and research experiences. finally, student recruitment and mentoring programs, unconscious bias training, ally workshops, and regular climate surveys will be developed to ensure **\*\*diversity\*\*** in the qist workforce. the project will train one-hundred and twenty-five (125) ms and ph.d. students, including thirty-five (35) fully-funded trainees. these efforts will result in an institutionalized program that produces leaders in qist for careers in academia, industry, government, and national labs. the research program addresses three grand challenges in quantum technology: (1) how can demonstrable quantum speed-up using existing or near-term quantum computing architectures be achieved? (2) how can materials and electrical engineering interface with quantum technology to provide meaningful advances in device development and fabrication? (3) how can new directions in quantum algorithms advance and challenge the notion that quantum technology can solve problems that are impossible to tackle with conventional technology? these interdisciplinary research challenges require close synergy between fundamental physics, materials science, electrical engineering, and algorithm development. new courses and

degree pathways in qist are being developed at both mines and sjsu, which include integration of professional skills development into the graduate curriculum. through classroom training and research, trainees will be exposed to the full range of quantum technology architectures, providing a holistic view of this rapidly developing field. an innovative educational agreement between mines and sjsu will provide opportunities for students to complete an ms/ph.d. bridge program from sjsu to mines. the program will result in a template for qist graduate education, which will be accessible to stem students from all backgrounds and types of institutions, increasing **\*\*diversity\*\*** in qist. the nsf research traineeship (nrt) program is designed to encourage the development and implementation of bold, new potentially transformative models for stem graduate education training. the program is dedicated to effective training of stem graduate students in high priority interdisciplinary or convergent research areas through comprehensive traineeship models that are innovative, evidence-based, and aligned with changing workforce and research needs. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Improving STEM Degree Completion with Professional Development to Support Inclusive and Equitable Classroom Practices

Awardee: University of California-Irvine

Amount: \$2,332,829.00

Abstract: with support from the improving undergraduate stem education: hispanic-serving institutions program (hsi program), this project aims to facilitate institutional transformation by addressing environmental factors that negatively influence stem degree completion for groups of students. the project will offer a series of workshops that promote inclusivity in stem fields by considering research on systemic issues and barriers to academic success. the project will seek to address degree completion disparities by providing faculty and administrators with activities,

exercises, and facilitated discussions of research literature to examine social and cultural factors associated with their own and their students' lived experiences at the institution. the project will also leverage existing efforts on campus that aim to create more inclusive academic spaces. by taking a collaborative research-oriented approach to working with faculty and administrators, the project will seek to provide processes that other institutions can follow. to directly address the importance of culture in the classroom, the project will employ a mixed methods research design, and a multi-session faculty professional development series integrated into the broader campus community, that provides faculty with a curriculum that will advance inclusion and equity in their learning spaces. three overarching goals guide this project. first is to lay a solid foundation of local and national data related to disparities in persistence and retention that will be used to inform participant practices and behaviors in the classroom. second is to increase awareness of the social and cultural locations of stem students. third is to modify classroom practices and policies in order to increase student engagement and success. several research questions will be explored by the project team. according to stem students, what social and cultural factors need to be considered to improve the classroom climate? what is the impact of participation in project activities on faculty conceptions of **diversity** and inclusion in the classroom? how does faculty participation in the project lead to increased implementation of evidence-based inclusive teaching? the key motivating factors for this project are to address systemic inequity that is manifested in stem degree completion disparities and to share methods, data, and findings with hsis across the country. dissemination efforts will include a project website for sharing pertinent project information, multiple research publications and presentations, a research conference on creating inclusive academic spaces, and strategic connections with existing programs that are part of the nsf includes network. the hsi program aims to enhance undergraduate stem education, broaden participation in stem, and build capacity at hsis. achieving these aims, given the diverse nature and context of the hsis, requires innovative approaches that incentivize institutional and community transformation and promote fundamental research (i) on engaged student learning, (ii) about what it takes to diversify and

increase participation in stem effectively, and (iii) that improves our understanding of how to build institutional capacity at hsis. projects supported by the hsi program will also draw from these approaches to generate new knowledge on how to achieve these aims. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: BPC-AE: STARS: Catalyzing Action-Oriented Academic Communities for Broadening Participation in Computing

Awardee: Temple University

Amount: \$2,237,296.00

Abstract: it is critical to address the longstanding issue of underrepresentation of women, black, and hispanic students in computing degree programs to provide an equitable foundation for all to participate in our society and the global economy as controllers and creators of technology, and to advance the preparation of a diverse, innovative, and competitive tech workforce. building on the prior success of the stars computing corps alliance for broadening participation in computing, the goal of the stars catalyst project is to: 1) increase the number of women, black, and hispanic students that persist in computing degree programs, and 2) advance the careers of students and faculty from groups that have been historically underrepresented in computing. through research and evaluation around stars catalyst activities, this project will advance knowledge about practices designed to increase persistence and support career advancement in computing for college computing students and faculty, particularly for those from underrepresented and intersectional groups in computing. the stars catalyst alliance is a collaborative effort across temple university, north carolina state, kent state, florida state university, morgan state, and university of north carolina charlotte. the stars computing corps alliance for broadening participation in computing (bpc) engages computing faculty and students at colleges, universities, and community colleges in a community of practice with a shared commitment to take action to advance **diversity**, equity, and inclusion in computing. stars computing corps conferences, communities, and networks create significant institutional and human resources that can expand bpc research to a larger audience of researchers, educators, administrators, cs departments, and k-20 students, and can dramatically increase the number of people taking action in bpc efforts. prior results show that the stars computing corps alliance increases intentions to persist in computing among stars students and faculty, with enhanced outcomes for black students and faculty. this project will significantly extend the stars alliance to expand upon those impacts, by 1) including new partners that expand the reach of stars and that emphasize participation of black and hispanic students and faculty, particularly from

emerging hispanic serving institutions and community colleges, 2) creating new program elements that test new and propagate evidence-based bpc practices within computing departments, and 3) leveraging partnerships to support identity-focused affinity groups, and 4) developing stars alumni groups employed in industry positions to promote transition to and retention within the tech workforce. extensions to the stars leadership corps program, stars launch program, and the stars celebration conference will serve to develop and propagate evidence-based approaches aimed at improving the teaching and learning of computing for black and hispanic students and build evidence of their effectiveness, and the respect research conference will continue to advance peer-reviewed bpc scholarship. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: URoL:EN: Towards a unified theory of regulatory functions and networks across biological and social systems

Awardee: Northwestern University

Amount: \$2,199,383.00

Abstract: complex organizational structures range from the very small (such as cells) to the very large (such as a system of government), and maintaining these structures requires a lot of energy and resources. consider, for example, the part of the us legal system that is devoted to handling lawsuits and resolving conflicts. the structure of the legal system includes the law itself, the attorneys, judges, and all the other people involved in bringing a lawsuit forward and ensuring that it is resolved. as a result, us companies spend a lot of funds on litigation alone. in us colleges, administrative spending is comparable with instructional spending and has been cited as a key factor in the increasing tuition of us universities. the continuing growth of these kinds of costs is a major challenge, but they aren't understood very well. when these costs are studied, they are often

viewed as hidden or unintended expenses that are unique to the systems in which they are found. the research supported by this grant develops a unified theoretical framework for studying regulatory mechanisms across different kinds of systems, from single cells to entire societies. the research improves society by suggesting ways to make the organization of institutions, such as companies, universities and governments, more efficient. regulatory functions and mechanisms are a necessary, essential, and ubiquitous feature across all biological, social, and mechanical systems. bacteria have regulatory genes, companies have managers, and car engines have engine control units. indeed, the challenge for all complex adaptive systems that aim to survive in multi-faceted and competitive environments is to optimally manage internal functions and interactions. the presence of regulatory mechanisms in complex systems is therefore a universal rule of life, and network structures emerge under the rule of life. this grant develops a unified science of regulatory functions and their associated emergent structures to answer questions such as: what causes an increase in regulatory costs? can we predict the amount of regulatory costs an organism or organization needs, based on its size, function, and complexity? is it necessary to grow the administrative or regulatory functions of a system to ensure the continued functioning of the system, or is it an unnecessary burden? this research develops scientific measurements to determine the appropriate or optimal size and network structure of bureaucracy for a system to perform its tasks. the research takes place in two steps: 1) gathering and organizing datasets that span biological and social systems; and 2) using these datasets to develop a theory for regulatory structures across a wide range of systems. the theory will start from a mathematical framework that describes cost as a function of the size and complexity of a system and integrate this theory with new results and models of the functional **\*\*diversity\*\*** of organizations and their structures. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: EFRI E3P: Supercritical Extraction for the Elimination of End-of-Life Plastics (SCE3P)

Awardee: Auburn University

Amount: \$2,174,344.00

Abstract: multilayer plastic packaging is critical to keeping a wide range of food products, including meats, juice pouches, cheeses, and prepared foods, safe during transportation and storage. to function, multiple materials are used together to meet requirements that individual materials cannot. however, most multilayer food packaging winds up in landfills because current recycling processes cannot separate the various components. in this project, researchers will use high pressure and high temperature to turn gases into supercritical fluids that enable separating the materials used in typical multilayer food packaging. the higher value of the resulting purer material streams will improve the economics of recycling multilayer structures. the process will be designed to allow straightforward implementation on equipment commonly found at existing recycling plants. the work will include a thorough assessment of both the economic and environmental impacts of increased recycling rates for multilayer packaging. if successful, the project will result in new technology that increases the recyclability of plastic waste, reduces the amount of plastic waste entering landfills, and limits the environmental impact of food packaging. the project will also enhance education, **\*\*diversity\*\***, and workforce development by combining efforts from a large four-year university, a historically black university, and a two-year community college in a highly interdisciplinary approach to addressing the research questions. graduate and undergraduate students participating in the research will cross-train at the partner institutions and develop community outreach activities on polymers, recycling, and related science for use at open houses and area classrooms. this project aims to valorize the multilayer polymer waste stream through a process designed to reclaim high-value barrier polymers from multilayer food packaging and simultaneously recycle the polyolefins. the investigators hypothesize: 1) supercritical co<sub>2</sub>, in combination with cosolvents, will improve the extraction of ethylene vinyl alcohol (evoh) and polyxylylene adipamide (mxd6) from multilayer systems by increasing the polymer concentration in the solvent phase and enhancing the solvent's

ability to penetrate the multilayer structure via plasticization, 2) modifying extrusion equipment to use supercritical fluids offers several advantages including enhanced layer separation and dissolution kinetics and reduced costs including overall recycling energy and recycling facility retrofitting expenses, 3) the materials reclaimed by this process will be suitable for use in closed-loop recycling, and 4) the proposed technology will increase overall recycling rates, having a net positive environmental impact. the work will increase our thermodynamic and kinetic understanding of the phase behavior of commercially important plastics and their mixtures in supercritical co<sub>2</sub> with cosolvents. fundamental understanding of how solvent choice, processing conditions (e.g., temperature and pressure), and extruder screw design impact partition coefficients and polymer extraction kinetics will be gained. a combination of techno-economic analysis, life-cycle assessment, and economic and environmental impact analysis will be used to establish the potential impact of recycling multilayer food packaging on the environment and determine the need for policy instruments to promote the recycling of these materials. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: AccelNet-Implementation: Crustal Ocean Biosphere Research Accelerator (COBRA)

Awardee: Bigelow Laboratory for Ocean Sciences

Amount: \$2,156,626.00

Abstract: the deep seafloor covers two-thirds of earth's surface area, but there is limited understanding of the deep-ocean ecosystems and resources and the ability of these ecosystems to withstand human impacts. human uses such as deep-sea mining and carbon sequestration are poised to fundamentally alter physical, chemical, and biological conditions of the seafloor and surrounding environments. these activities have the potential to rival negative effects from bottom fishing and other human impacts to the deep sea, yet the science to inform and evaluate the

impacts of these new industries is lacking. the crustal ocean biosphere research accelerator (cobra) project connects diverse stakeholders and experts ? interdisciplinary academic and government scientists, private institutions, policy makers, industry experts and other stakeholders ? through virtual meetings to coordinate efforts. the goal is to generate new knowledge and inform decision-making relating to emergent industrial uses of the deep ocean and decrease the likelihood of serious harm to the environment while maintaining the broad benefits that society currently enjoys. the cobra network of networks has nine key partners that bring access to international science and crustal ocean exploration assets (ocean exploration trust, schmidt ocean institute, ocean networks canada, cluster ocean floor at marum, and c-deepsea), to experts that provide science-based recommendations to policy makers (deep ocean stewardship initiative working groups, including the challenger 150 program), to governmental groups responsible for assessing crustal ocean resources (usgs global marine minerals group), and to experts in team science (credits program). cobra unites these partners in a common mission to accelerate research on the structure, function, resilience, and ecosystem services of the crustal ocean biosphere to inform decision making. cobra will help to close knowledge gaps by facilitating dedicated and coordinated expedition and observatory efforts combined with emergent characterization approaches. in parallel, cobra will train at least 50 globally distributed early-career researchers in ocean exploration, science, and policy through innovative virtual expedition leadership training and support two dozen international research exchanges that promote team science collaboration, **\*\*diversity\*\***, equity, and inclusivity. cobra will also establish a web-based search portal that points to all data types deposited in appropriate internationally accessible data repositories to promote data discovery and accelerate knowledge transfer and collaboration.

the accelerating research through international network-to-network collaborations (accelnet) program is designed to accelerate the process of scientific discovery and prepare the next generation of u.s. researchers for multiteam international collaborations. the accelnet program supports strategic linkages among u.s. research networks and complementary networks abroad that will leverage research and educational resources to tackle

grand scientific challenges that require significant coordinated international efforts. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: RCN: LEAPS: Rooting Out Oppression Together and SHaring Our Outcomes Transparently

Awardee: American Society of Plant Biologists

Amount: \$2,141,750.00

Abstract: the demographic distribution of scientists, especially those in positions of authority, does not reflect that of the us population. some of the causes of this disparity are known, such as a lack of role models and the tendency for people to look within their own circles when they recruit, appoint, and promote. this award will provide resources, trainings, opportunities, and structures that

will allow participating plant science and affiliated organizations to change that construct by rooting out oppression together (root) and sharing our outcomes transparently (shoot). the network is unusual in its breadth and scope, and it extends upon previous collaborative activities in the plant sciences by incorporating partners that serve underrepresented populations, as well as other non-profits and companies. the participating organizations have each independently begun this work, and through this award they will coordinate to exert meaningful and lasting change to reshape the plant science community into one that is truly equitable, inclusive, and anti-racist. the network partners will design and implement interventions to remove barriers that prevent the participation and success of individuals historically excluded from leadership and influence roles in science, assess the success of these interventions, and share the outcomes. broadly sharing the lessons and outcomes from this deep and careful self-study will inform other organizations and professional societies as they strive towards becoming more inclusive and diverse scientific communities. the goal of the rooting out oppression together (root) and sharing our outcomes transparently (shoot) research coordination network (rcn) is to develop a collaborative network that facilitates cultural changes throughout the plant sciences to advance **diversity**, equity, and inclusion. the network will coordinate the development and dissemination of resources for building and sustaining equitable and inclusive scientific organizations, including assessment tools and equity action plans. it will provide broad training of the plant science communities in equitable practices and operations, while implementing dual-membership programs and shared participation in conferences. hundreds of scholars and practitioners will be trained in topics such as inclusive teamwork, climate and culture assessment, and culturally responsive mentoring, even as the participating organizations themselves implement well-informed changes to their governance and leadership structures. the network will create shared web pages, guides, workshops, webinars, and action plans to educate and inform our community members and others across stem. the rcn initially consists of seven plant science professional societies and organizations; it has also established formal partnerships with organizations committed to supporting underrepresented and marginalized scientists, as well as

industry partners. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: NRT: Research Training in Sustainable Packaging and Biodegradable Polymer Composites for the Next Generation of STEM Graduates

Awardee: Tuskegee University

Amount: \$2,122,103.00

Abstract: this award is funded in whole or in part under the american rescue plan act of 2021 (public law 117-2). current generation packaging materials are made of polymer composites that are derived from petroleum sources. these materials are not degradable and either end up in landfills or are incinerated, releasing toxic gases. factors such as greater environmental awareness, societal concerns, and the depletion of petrochemical resources collectively drive a desire to develop new

materials and products based on plant fibers and degradable biopolymers. this national science foundation research traineeship (nrt) award to tuskegee university will establish a multidisciplinary traineeship in sustainable nanobiomaterials. the program is a partnership between three doctoral programs to collaboratively develop innovative sustainable biomaterials for biodegradable packaging systems, including biomedical and food packaging. the project anticipates training 40 students (30 ph.d. and 10 masters), including 30 funded trainees, from materials science and engineering, integrative biosciences, and integrative pathobiology. the tuskegee nrt effort will produce a large number of minority graduates, including a significant number of women with ph.d. degrees in stem. an area of focus for the traineeship includes support and training of faculty to mentor the trainees and provide trainees with training and opportunities to mentor as well. these graduates will become excellent role models for many young students and help bring much-needed **\*\*diversity\*\*** to the nation's advanced technological workforce in sustainable nanobiomaterials. the multidisciplinary project team will train emerging scientists, engineers, entrepreneurs, and managers to develop the next generation of sustainable, biodegradable food and medical packaging applications. the trainees will carry out research in: (a) synthesis of calcium and silica-based nanoparticles from waste resources such as bone ash, fish scales, egg and seashells, (b) antimicrobial functionalization of nanoparticles and short plant fibers using green synthesis methods, (c) structural, morphological, and spectral characterization of as-prepared nanoparticles, (d) fabrication of antimicrobial polymer packaging films using polymer blow films, 3d printing, and solution casting, (e) nanomechanical, structural, morphological, and thermal characterization of as-prepared polymer composite films, and (f) antimicrobial inhibition, product design, prototyping, biodegradability, and commercial feasibility studies. the knowledge and training gained by the trainees will eventually result in new design and manufacturing methodologies. the program emphasizes mentoring at three levels. students will be co-advised and mentored by a minimum of two faculty members. faculty and trainees will be involved in outreach to and mentoring of high school students. moreover, an annual mentoring workshop will be conducted to provide both faculty and trainees with strategies for effective

mentoring. other professional development activities are also in place to ensure students receive formal and informal preparation in proposal development and technical writing, teamwork, and ethics. the nsf research traineeship (nrt) program is designed to encourage the development and implementation of bold, new, potentially transformative models for stem graduate education training. the program is dedicated to effective training of stem graduate students in high priority interdisciplinary or convergent research areas through comprehensive traineeship models that are innovative, evidence-based, and aligned with changing workforce and research needs. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: AccelNet-Implementation: FLUXNET Coordination to Understand Ecosystem Function through Continuous Observations of Ecosystem-Atmosphere Interactions

Awardee: University of California-Berkeley

Amount: \$2,033,930.00

Abstract: global ecosystems provide services that sustain society, including providing food, fiber and timber, and water cycle regulation. an important service is the sequestering of carbon dioxide from the atmosphere, which greatly slows the rate of climate change. understanding ecosystem-atmosphere interactions, and the response of these to environmental change, is an urgent challenge. this accelnet implementation track award will link over ten existing national and international networks focused on continuous observations of ecosystem-atmosphere interactions at over 1000 locations around the world. the fluxnet coordination project will fill fundamental knowledge gaps in science, engineering, and societal issues associated with ongoing changes in ecosystem function and the related cycling of carbon and water. fluxnet is a global network of regional networks, consisting of scientists measuring the exchange of carbon dioxide, water, energy, and other greenhouse gas fluxes between ecosystems and the atmosphere. this project will

develop the next generation of the fluxnet network of networks to be a self-sustaining global collaboration focused on supporting early career scientists, expanding the **\*\*diversity\*\*** of scientists, biomes, and climate regions involved, and empowering international collaboration. given the **\*\*diversity\*\*** of life on earth, a full understanding of the role of ecosystems in the earth system can only be achieved through a network-of-networks approach. the central goals of the fluxnet coordination project are to provide novel training and exchange opportunities, develop strong international collaborations, and build tools and protocols that ensure continued capacity of fluxnet to provide continuous observations of ecosystem-atmosphere interactions across the globe. such measurements have proven essential for understanding ecosystem function, calibrating space-borne observations, and developing models used to project future climate. the project will develop data-focused processing protocols and pipelines, as well as people-focused education and exchange opportunities. network activities include annual in-person meetings at national and international venues, monthly webinars, workshops and synthesis publications, and student and early-career researcher personnel exchanges. the project will use creative and transformative approaches to international collaboration and networked science to achieve its goal of building the next generation of fluxnet to be a self-sustaining flagship of networked global scientific cooperation.

the accelerating research through international network-to-network collaborations (accelnet) program is designed to accelerate the process of scientific discovery and prepare the next generation of u.s. researchers for multiteam international collaborations. the accelnet program supports strategic linkages among u.s. research networks and complementary networks abroad that will leverage research and educational resources to tackle grand scientific challenges that require significant coordinated international efforts. co-funding for this award is provided by the macrosystems biology and neon-enabled science program and the neon program in the directorate for biological sciences. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: LEAP-HI: AI-Optimized 3D Printing of Super-Soft Materials for Personalized Sensing

Awardee: Iowa State University

Amount: \$2,008,000.00

Abstract: a common need in the medical community is an ability to monitor local tissue continuously, but current sensing technology lacks the personalization necessary to contour sensors for the unique anatomy of different individuals. this leading engineering for america's prosperity, health, and infrastructure (leap-hi) research seeks to develop low-cost personalized sensors which can be fabricated on demand to enhance the health and well-being of americans from all walks of life. the approach leverages fundamental research into new materials in tandem with advanced machine learning and artificial intelligence to "3d print" personalized sensors with applications in health care?from prosthetics to diagnostics and therapeutics?that could impact millions of people. these advances spanning materials science, engineering, and computation will improve the economic competitiveness of the united states? innovation and help train the next generation of scientists and engineers through a tight synergy between experimental and computational research. a series of initiatives spanning **\*\*diversity\*\***, education, and outreach to further will advance key aspects of the work across age groups. this includes (a) modules on cybermanufacturing in a new cyber physical systems minor at iowa state university, (b) working with the local chapters of society for advancement of chicanos/hispanics, native americans in science, and the national society of black engineers to draw students into research, (c) k-12 engagement through activities at the wolf museum of exploration and innovation (moxi) for children, (d) working with center for industrial research and service (ciras) to disseminate best practices and training modules in cyber manufacturing, and (e) working with the communications offices of both the university of california at santa barbara and iowa state university to disseminate the research to the public to promote the need for engineering leadership in the united states. this research will overcome the limitations of

conventional sensor technologies for personalized health monitoring by developing new materials and processing techniques to 3d print polymers with mechanical properties that are matched to human tissue. our strategy will yield fundamental insights into the translation of advanced materials to manufacturing by: (1) designing and synthesizing materials that inherently provide processability for 3d printing while maintaining biocompatibility and mechanical function; (2) advanced multi-scale simulations of the printing process through modeling and predictive dynamics at the device scale to understand macroscopic progression during the build process, and at the microstructure scale to tailor the material properties as a function of material deposition and curing; (3) data fusion from sensor response and physics-aware machine learning models to enable real-time prediction and control of the 3d printing process; and (4) creating ultra-soft structured sensors that enable unique sensing modalities for societal impact in personalized human health. these research aims to harness the data revolution by exploiting computational and machine-learning models to design more effective polymers and sensors in a convergent fashion. this research will yield experimental and computational methodologies that can also be applied to other engineering disciplines. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Dimensions US-São Paulo: Animal biases in fruit selection and seed dispersal as drivers of biotic filters in the assembly of successional forests and their carbon capture potential

Awardee: Pennsylvania State Univ University Park

Amount: \$1,995,178.00

Abstract: tropical forests play a major role in regulating the earth's climate through their effects on water cycles and their large capacity to remove and store atmospheric carbon. because of their global preeminence as life-supporting systems and the widespread threats they face, understanding how tropical forests regenerate, store carbon, and maintain high bio\*\*diversity\*\* levels is urgent. the

project will advance the understanding of the roles that animal-plant mutualisms, involving animals that eat fruit and disperse seeds, affect the tree composition, **diversity**, growth rates, and soil-microbe communities that influence forest growth and atmospheric carbon storage potential. the project will advance the practical principles that promote cost reduction and maximization of **diversity** conservation in restored forested areas. the project fosters international collaboration and cross-fertilization between brazilian and us scientists and the mentoring of junior faculty, postdocs, and students of all levels. specifically project will train at least 10 graduate and 40 undergraduate students, and develop a field biology course for students of diverse backgrounds. community outreach activities include involvement of rural school students from middle and high school in science-learning activities at the classroom and the field study site. the project builds around three aims that link phylogenetic, genetic, and functional aspects of **diversity** in the context of the role of plant-frugivore mutualisms (fsd) on community assembly patterns of early-successional tropical forests. with an well-replicated experimental design that strategically incorporates functional plant traits and phylogenetic relationships as fixed-effects, the project test functional relationships between fsd processes and phylogeny on community assembly. the project then examines how the interaction of fsd processes with the functional-phylogenetic traits of pioneer plants affect the genetic **diversity** of the colonizer species that follow, and in turn, how patterns of genetic **diversity** lead to differences in plant survival, growth, and community assembly. the project ultimately explores how the biotic filtering interactions of fsd processes and the functional and phylogenetic traits of successional communities influence, or are influenced by, soil microbiomes and the nutrient pools and carbon transformation processes they control. the project advances basic knowledge by exploring mechanisms and outcomes across diverse scales of biological organization rarely brought together in a single experimental framework: from trophic interactions and dispersal processes, to soil microbes and their biogeochemical cycling effects. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: AccelNet-Implementation: Implementing a Deep Ocean Observing Strategy (iDOOS)

Awardee: University of Texas at Austin

Amount: \$1,992,928.00

Abstract: the deep ocean below 200 m is poorly known. this dynamic realm is a vast repository for bio\*\*diversity\*\*, provides critical climate regulation, and houses a wealth of hydrocarbon, mineral, and genetic resources. observing the deep ocean at a level required to inform sustainable development and management faces significant technical and logistical challenges. to address these challenges, the idoos project will implement a deep-ocean observing strategy (doos) that brings together u.s. and international networks engaged in sustained deep-ocean observing, mapping, exploration, modeling, research, and management to leverage each other's efforts, knowledge, and resources. this implementation project will boost the doos community-driven initiative, working under the umbrella of the global ocean observing system (goos) and endorsed as a united nations ocean decade action. by connecting deep-ocean observers across disciplines, expanding the observing community to include non-traditional partners, and linking data providers to users, idoos will enhance the goos deep-ocean capabilities and target societal needs. through engagement with policy makers, regulators, and science coordinators, idoos will raise awareness and support for deep-ocean science, and bring science into critical decisions regarding climate, bio\*\*diversity\*\* and sustainability. idoos will foster a community of future leaders informed in deep-ocean observing, modeling, and data science at a global level who are adept at communicating to regulators and policy makers as well as fellow scientists. idoos addresses three main themes: (1) requirement setting for deep ocean observing; (2) promoting the coordination and implementation of integrated observing to address sustainable development goals and societal needs; and (3) translating knowledge and data to allow science-based decision-making, regulation and governance of the global deep ocean. these themes will be integrated and applied via the

framework of regional demonstration projects. idoos will work with the goos disciplinary expert panels to refine essential ocean variables in terms of deep ocean requirements, and with network partners to maximize their implementation and use. in addition, the project has two cross-cutting activities. a focus on data/informatics will contribute best practices and standards to the requirement-setting theme, support activities across the working groups, and offer tailored training to early-career researchers. the project aims to enable findable, accessible, interoperable, and reusable (fair) deep-sea data and a data-enabled, deep-sea workforce. a key element of idoos is the mentorship and training of the next generation. idoos will assemble a network of deep ocean early career researchers (doers) drawing from collaborating networks, the broader deep-ocean observing community, as well as from developing countries and indigenous communities. through the theme working groups, the project will conduct training activities and meetings to substantially improve justice, equity, **\*\*diversity\*\***, inclusion, and belonging among the participating networks and more broadly within deep-ocean science. the accelerating research through international network-to-network collaborations (accelnet) program is designed to accelerate the process of scientific discovery and prepare the next generation of u.s. researchers for multiteam international collaborations. the accelnet program supports strategic linkages among u.s. research networks and complementary networks abroad that will leverage research and educational resources to tackle grand scientific challenges that require significant coordinated international efforts. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: MIM: Elucidating the Rules of Cooperation and Resiliency in Microbial Communities through Stochastic Graph Grammars

Awardee: William Marsh Rice University

Amount: \$1,989,933.00

Abstract: microbial communities in aquatic ecosystems are central to maintaining the resiliency of these important environments. these dense microbial populations are rich in species **diversity** and their genomes are dynamic because of processes such as gene duplication and horizontal gene transfer. despite extensive genomic flux due to these evolutionary processes, microbial communities cooperate and maintain stable interactions and are resilient to environmental perturbations. this project aims to develop a suite of computational tools for deciphering the rules that govern cooperation and resiliency in hot spring microbial mats, or biofilms, from yellowstone park. these well-studied environments are ideal for examining how critical environmental parameters such as temperature, light and nutrients influence the **diversity**, abundance, and evolution of microbial populations. novel computational tools will be developed to identify rules that govern relevant biological processes. understanding how microbiomes evolve and adapt, especially with respect to the environment and to perturbations is crucial to understand many aspects of life. thus, the results obtained from this project will have a significant impact on biology, health, conservation efforts, and animal and plant management. furthermore, this research will support the interdisciplinary development of a diverse cohort of phd and undergraduate students at rice university and carnegie institution for science located on the stanford university campus. this project will also support the development of a summer reu focused on bioinformatics, ecology, evolution, and microbiology, and will also include summer training opportunities for graduate students with collaborators at the pasteur institute in paris, france. this collaborative, multidisciplinary project presents an innovative plan for combining education and outreach activities to achieve real and lasting impact. all software developed will be made available on open-source code repositories. the overall goal of the project is to understand how microbiomes evolve and adapt, especially with respect to the environment and to perturbations. to meet these goals, the team of researchers will introduce methodological advances at the intersection of graph theory, formal languages, and machine learning to identify rules governing gene duplication and horizontal gene transfer from metagenomic sequencing data. in aim 1, the project will construct and correlate species abundance networks with genome

exchange networks through genome assembly graphs. in aim 2, the project will produce a stochastic graph grammar framework for modeling network evolution over time, as well as unveil new rules with deep graph generators. in aim 3, genome-level simulations will be combined with the genomic events identified in aims 1 and 2 to assess the evolutionary benefits of these biological processes and their associated rates. the final project aim will focus on characterizing cooperation and resiliency through the study of graph grammars and network analysis techniques. the open-source computational methods developed across all four project aims will be evaluated on four distinct metagenomic datasets, including both environmental and host-associated microbiomes. finally, a wide variety of metagenomic datasets will be used to show generalizability of the computational approaches to host-associated microbiomes. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: A framework for reconciling competing effects of competitors on disease transmission

Awardee: University of Montana

Amount: \$1,979,823.00

Abstract: bio\*\*diversity\*\* is disappearing at an alarming rate, and at the same time, infectious diseases increasingly spill over from wildlife to humans. therefore, it is urgent to understand how species \*\*diversity\*\* affects infectious diseases in wildlife. in some ecosystems, increasing \*\*diversity\*\* of competitor species decreases disease risk, termed the 'dilution' effect because \*\*diversity\*\* dilutes out infection. however, in other systems, a more diverse community increases disease risk, termed the 'amplification' effect. when to expect dilution or amplification is a topic of debate among disease ecologists. this project aims to reconcile the competing effects of bio\*\*diversity\*\* using sin nombre hantavirus (snv) in deer mice as a model. this system displays aspects of both dilution and amplification at the same time. this project lays out a framework for

examining potential mechanisms of dilution and amplification and how they can interact to potentially be synergistic or antagonistic. this will facilitate moving beyond the long-standing debate of which pattern (dilution or amplification) is more prevalent, clarifying when different mechanisms may be dominant and help explain the different patterns seen in various studies. it will also benefit society by advancing prevention efforts for hantavirus pulmonary syndrome (hps). this human illness caused by snv, has affected more than 700 people (killing more than 250) since its discovery in 1993. other broader impacts of this research include outreach and work with native americans, with particular focus on k-12 outreach.

three mechanisms determine if increasing competitor **\*\*diversity\*\*** will lead to dilution or amplification of a directly transmitted pathogen. dilution will occur if increased species **\*\*diversity\*\*** leads to 1) decreased host density, 2) decreased contact rates, or 3) decreased probability of transmission given contact (transmissibility). conversely, amplification could occur if increased **\*\*diversity\*\*** does the opposite. this project develops a framework to disentangle these component dilution and amplification effects, centered around a mathematical model that combines sir (susceptible-infected-recovered) dynamics with a lotka-volterra competition coefficient. aim 1 is to determine how increased small mammal **\*\*diversity\*\*** / composition affects mouse population demography and subsequent snv prevalence, by performing bayesian population analyses on longitudinal data. aim 2 is to determine how increased small mammal **\*\*diversity\*\*** affects the transmission rate, through changes in transmissibility (via stress, co-infections, immunity, and viral shedding) and/or contact rates between deer mice, using a combination of long-term monitoring of physiology in natural populations, and experimental manipulation in the field. aim 3 is to synthesize the findings from aims 1 and 2 into a general model of how competitors can differentially affect all three components of transmission and scale up to determine the variety of observed patterns in disease prevalence within and across systems.

Title: Collaborative Research: GRate ? Integrating data and modeling to quantify rates of Greenland Ice Sheet change, Holocene to future

Awardee: SUNY at Buffalo

Amount: \$1,891,148.00

Abstract: the greenland ice sheet has experienced devastating melt in recent years. recent scientific reports highlight how vulnerable the greenland ice sheet is to arctic climate change and draw a dire picture of the impact of sea-level rise. in order to equip society with the best forecasts of sea level rise for planning, scientists need to improve the ability to simulate ? or model ? the response of ice sheets to climate change. for this project, scientists from different branches of ice-sheet research will work together to improve ice sheet modelling. the researchers will leverage recent scientific

advances to model the entire Greenland ice sheet in order to investigate long-term ice-sheet sensitivity to changes taking place in the ocean and atmosphere. The research group is committed to creating an inclusive environment where all team members can learn and excel. The team contains **diversity** in ethnicity, gender and rank, and will train six early career scholars, recruiting specifically from groups underrepresented in the geosciences, which is among the least diverse STEM fields in the U.S. Results will be made publicly available and will facilitate a broad range of future research about the Arctic system, including ice sheet modeling, model spin-up, paleoclimate reconstruction/synthesis and glacier history. To elevate the capacity of outreach and education programs developed during their first project, the team will build on their "scientists are superheroes" outreach program and leverage other, existing outreach frameworks, including making connections with Greenlandic communities and with high school student intern programs at their universities linked to the Young Women's Leadership School (Bronx, NY) and the Spring Valley (NY) branch of the NAACP, coordinated by our dedicated project educator and outreach specialist.

Reducing uncertainties in ice-sheet model predictions is crucial in society's handling of the sea level crisis. Uncertainties related to ice-sheet instability arise from limited observations, inadequate model representation of ice-sheet processes, and limited understanding of the complex interactions between the atmosphere, ocean, and ice sheets. How atmospheric and oceanic forcing vary through time, and at what timescales each are capable of forcing rapid change, are critical for predicting future ice mass loss, but scientists have been observing ice sheet change for only a short period of time (decades). The PIs propose to scrutinize Greenland ice sheet change spanning from the beginning of the Holocene (12,000 years ago) to 2100 CE, making it possible to evaluate the varying roles of atmospheric and ocean forcing on decadal-to-centennial timescales relevant for the future Greenland ice sheet evolution. The PIs will utilize their established multi-disciplinary collaboration to combine ice sheet modelling, climate forcing and reconstructions of past ice-sheet change. This will position the team to make predictions of future ice sheet change that are grounded in Greenland ice sheet behavior during past climate swings that occurred prior to our brief window of modern

observation. the work will lead to lasting products to serve the community's collective effort to better understand ice sheet change: 1) a state-of-the-art ice-sheet model optimized for simulations over long timescales, 2) a holocene-through-modern set of atmospheric and ocean state estimates optimized for forcing an ice-sheet model, and 3) a database of past-ice sheet configurations and paleoclimate records formatted for model-data comparison. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: CCRI: ENS: Cognitive Hardware and Software Ecosystem Community Infrastructure (CHASE-CI)

Awardee: University of California-San Diego

Amount: \$1,882,000.00

Abstract: machine learning (ml) is a rapidly expanding field. computationally intensive workflows train neural nets and then use the results in smartphones, robots, drones, self-driving vehicles, and to run the internet of things. access to graphics processing units (gpus) is provided through chase-ci's nautilus, a highly distributed but centrally managed on-demand computer cluster designed for ml and computational media (cm). chase-ci provides over 20 campuses the scaffold for adding on-premises compute cycles and fast data handling and it offers researcher-focused support and training. using chase-ci's detailed measurements of performance, researchers learn to become experts in optimization of their computational resources. chase-ci is a community-building effort that sustains a growing community of ml/cm researchers using a purpose-built continuously enhanced nationally distributed computing and data storage infrastructure. researchers explore combinations of algorithms and architectures optimized with the help of graphed performance metrics. researchers benefit from extensive shared workflows and open-source software. they use chase-ci's on-line social media platform to receive and give support and share techniques.

community use of chase-ci informs computer architecture discussions about future national cyberinfrastructure research and instructional lab needs. chase-ci forms a national on-line community that is easy to join, designed for sharing code, data, and results. the hardware, software, and socio-technical approaches developed by chase-ci have provided a roadmap for broader research uses and student training in ml/cm technologies. researchers get expanded access to hundreds of gpus for developing algorithms and software to train sensing devices and visualize results thus engaging the students who will soon join the essential workforce for the ongoing massive expansion of mobile platforms such as robots, drones, and self-driving cars. chase-ci impacts social **\*\*diversity\*\*** in computer science, broadening participation among minority-serving institutions and underserved states. chase-ci thoroughly measures and monitors data access by applications over the regional and national r&e networks. the repository for the project may be found at [prp.ucsd.edu](http://prp.ucsd.edu), to be maintained for the length of the project at a minimum. it is the anchor website containing pointers to all the research efforts that build upon the pacific research platform. it contains code repositories, presentations, references like publications, presentations, and recorded lectures, and it maintains and archives an active social media channel. chase-ci is led by uc san diego, partnering with investigators at uc santa cruz, the university of nebraska-lincoln, florida agricultural and mechanical university, new york university, the university of illinois at chicago, and san diego state university. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: WINTRE-MIX: Winter Precipitation Type Research Multi-scale Experiment

Awardee: University of Colorado at Boulder

Amount: \$1,837,002.00

Abstract: during near-freezing weather conditions, a **\*\*diversity\*\*** of surface precipitation types are possible, including: rain, drizzle, freezing rain, freezing drizzle, wet snow, ice pellets, and snow. such near freezing precipitation affects wide swaths of the united states and canada, impacting aviation, road transportation, power generation and distribution, winter recreation, ecology, and hydrology. this award is for a field experiment, named the winter precipitation type research multi-scale experiment (wintre-mix) with the overarching goal of improving understanding of how a variety of processes influence the variability and predictability of the type and amount of precipitation that falls during winter weather events. the project has direct societal impact through the potential for improved forecasting of these events. additionally, the project will have significant student involvement, public outreach events, and citizen science participation. the wintre-mix campaign will be conducted in southern quebec, canada and northern ny and vt in the united states. the canadian national research council convair-580 research aircraft and the university of illinois mobile radars will be deployed along with a host of surface-based instrumentation in february and march of

2022 to make observations that can be used to determine the thermodynamic, dynamic, and microphysical processes that interact to determine near-freezing precipitation type. more specifically, the project has three overarching scientific questions that will be addressed using observations, analysis, and modeling: 1) how do mesoscale dynamics modulate near-freezing precipitation, 2) how do microscale processes modulate near-freezing precipitation, and 3) how do multi-scale processes combine to determine the predictability of near-freezing precipitation? this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: EDGE FGT: Bee Functional Genomics Using Engineered Symbionts

Awardee: University of Texas at Austin

Amount: \$1,820,000.00

Abstract: insects are among the most widespread and diverse animals on our planet. they have critical roles in natural ecosystems and agriculture and have evolved unique biomaterials and lifestyles. scientific tools for studying the functions of the genes responsible for these traits are well-established for only a few types of insects, such as fruit flies. genetic tools do not exist for millions of other species. honey bees and bumblebees are economically important as widespread pollinators of food crops and are scientifically interesting due to the complex social behaviors observed in bee colonies. currently, there are few effective tools for studying the functions of bee genes. this project will develop and disseminate a toolkit that allows researchers to alter the expression of bee genes by engineering their native symbiotic gut bacteria. this technology will enable studies of how specific genes contribute to bee physiology, development, and behavior. this work will contribute to understanding bee ecology and health in ways that are expected to benefit bio\*\*diversity\*\* and us food security in the long term. the technology for engineering symbiotic bacteria is expected to be widely applicable to studying other insect species. these research and

outreach activities will be integrated with education by supporting two experiential learning courses that are part of the freshman research initiative program at the university of texas at austin. supporting this program will foster the development of a diverse science and technology workforce by involving underrepresented and first-generation college students in genuine research experiences. silencing the expression of a gene by inducing an rna interference (rna) response is a common approach for performing studies of gene function in invertebrates. however, delivering enough double-stranded rna to achieve sufficient gene knockdown through injection or feeding is expensive and ineffective in many insects, including bees. in this project, a functional genomics using engineered symbionts (fugues) methodology will be developed and applied to honey bees (*apis mellifera*) and bumblebees (*bombus* spp.). in fugues, microbial symbionts are engineered to continuously produce and deliver double-stranded rna to induce a targeted rna response in their host. newly emerged bees colonized with an engineered bacterial symbiont exhibit reduced expression of a target gene throughout the bee body, enabling one to ascertain the function of a bee gene and its role in determining specific phenotypes. there are key advantages of using fugues to study gene function over current techniques that generate transgenic animals: it can be accomplished more quickly, it can be conducted in high-throughput when coupled with insect colonization via feeding, and it can be applied to species, such as bees, with mating systems and collective behaviors that complicate using genome editing techniques. improving and disseminating the fugues tools created in this work will broadly enable studies of genes underlying bee behavior, development, and physiology. these tools will likely also be useful for studying many other insect species and other organisms that harbor symbiotic bacteria. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: EDGE FGT: Bee Functional Genomics Using Engineered Symbionts

Awardee: University of Texas at Austin

Amount: \$1,820,000.00

Abstract: insects are among the most widespread and diverse animals on our planet. they have critical roles in natural ecosystems and agriculture and have evolved unique biomaterials and lifestyles. scientific tools for studying the functions of the genes responsible for these traits are well-established for only a few types of insects, such as fruit flies. genetic tools do not exist for millions of other species. honey bees and bumblebees are economically important as widespread pollinators of food crops and are scientifically interesting due to the complex social behaviors observed in bee colonies. currently, there are few effective tools for studying the functions of bee genes. this project will develop and disseminate a toolkit that allows researchers to alter the expression of bee genes by engineering their native symbiotic gut bacteria. this technology will enable studies of how specific genes contribute to bee physiology, development, and behavior. this work will contribute to understanding bee ecology and health in ways that are expected to benefit bio\*\*diversity\*\* and us food security in the long term. the technology for engineering symbiotic bacteria is expected to be widely applicable to studying other insect species. these research and outreach activities will be integrated with education by supporting two experiential learning courses that are part of the freshman research initiative program at the university of texas at austin. supporting this program will foster the development of a diverse science and technology workforce by involving underrepresented and first-generation college students in genuine research experiences. silencing the expression of a gene by inducing an rna interference (rnai) response is a common approach for performing studies of gene function in invertebrates. however, delivering enough double-stranded rna to achieve sufficient gene knockdown through injection or feeding is expensive and ineffective in many insects, including bees. in this project, a functional genomics using engineered symbionts (fugues) methodology will be developed and applied to honey bees (*apis mellifera*) and bumblebees (*bombus* spp.). in fugues, microbial symbionts are engineered to continuously produce and deliver double-stranded rna to induce a targeted rnai response in their

host. newly emerged bees colonized with an engineered bacterial symbiont exhibit reduced expression of a target gene throughout the bee body, enabling one to ascertain the function of a bee gene and its role in determining specific phenotypes. there are key advantages of using fugues to study gene function over current techniques that generate transgenic animals: it can be accomplished more quickly, it can be conducted in high-throughput when coupled with insect colonization via feeding, and it can be applied to species, such as bees, with mating systems and collective behaviors that complicate using genome editing techniques. improving and disseminating the fugues tools created in this work will broadly enable studies of genes underlying bee behavior, development, and physiology. these tools will likely also be useful for studying many other insect species and other organisms that harbor symbiotic bacteria. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: RESEARCH-PGR: Genetic and environmentally-induced functional variation in the rice RNA structurome

Awardee: Pennsylvania State Univ University Park

Amount: \$1,800,000.00

Abstract: ribonucleic acids (rna) are essential molecules in living organisms, including in plants. rna can serve roles as both an informational molecule (genetic code) and a functional molecule (perform and regulate chemical reactions). rna can fold into complex shapes that can control whether it stays intact or is degraded. this in turn can control how a plant responds to environmental stresses it faces such as heat and cold. the research involves the development of new experimental technologies to investigate rna structures one molecule at a time and new computational technologies of artificial intelligence wherein a computer learns patterns that can predict rna structure and its variation. rice is an important world-wide crop, and the research applies these

technologies to rice varieties that are grown in different parts of the world. there are thousands of different varieties of rice adapted to local environments and their rnas often differ from each other by relatively few changes. some of these changes will alter the shape of the rna and thus the response of that rice variety to stress. a major goal of these study is to identify those changes that alter rna shape and thereby affect temperature tolerance. once identified, these shape-shifters could be engineered into specific rice varieties to breed crops more resistant to stress. aspects of the research will involve high school students and their teachers, and research results and methods will be disseminated in public outreach activities. rna structure is a primary determinant of gene expression. individual copies of the same transcript can take on different structures as influenced by their microenvironment, but methods have been lacking to categorize this **\*\*diversity\*\***. single nucleotide polymorphisms (snps) also can affect rna structure as ?ribosnitches?; however, ribosnitches have not been studied in plants, and their conditionality on environmental conditions has not been assessed. using rice (*oryza sativa*) as the primary model system, the proposed research will develop new wet bench and computational approaches that will allow categorization of the mrna ?pan-structurome,? its consequent impacts on gene expression, and its functional association with respect to local climate conditions in rice landraces. training will be provided to postdoctoral fellows, graduate students, undergraduates, and high school students and teachers. broader impacts will include development of the *oryza* climtools webtool to relate rice genotypes with climate variables and to identify beneficial structural haplotypes for use in development of elite rice cultivars. impact will be broadened through technology including enhanced browser-based rna structure-reactivity visualization and publicly available instructional screencasts. collaborations with pui swarthmore college will engage undergraduate researchers in computational aspects of the project. local high school students will perform whole plant physiological experiments, engaging a future generation of biologists and chemists. finally, the 23rd penn state plant biology symposium, on rna biology, will be organized, which will promote the global field of post-transcriptional gene regulation. this award was co-funded by the plant genome research program in the division of

integrative organismal systems and the genetic mechanisms cluster in the division of molecular and cellular biosciences. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: CCI Phase I: NSF Center for Quantum Dynamics on Modular Quantum Devices (CQD-MQD)

Awardee: Yale University

Amount: \$1,800,000.00

Abstract: the nsf center for quantum dynamics on modular quantum devices (cq-d-mqd) is supported by the centers for chemical innovation (cci) program of the division of chemistry. this phase i center is led by professor victor batista from yale university. other team members include professors michel devoret from yale university, sabre kais from purdue university, lea ferreira dos santos from yeshiva university, and eitan geva from the university of michigan. the project is motivated by the huge gap that currently exists between the problems for which a quantum computer could be useful in chemistry and what can actually be simulated today with state-of-the-art quantum computers. the challenge is that most well-known quantum computing (qc) algorithms have hardware requirements that far exceed the capabilities of current state-of-the-art quantum computers by several orders of magnitude. closing that qc gap is thus essential to make qc technology finally available to studies of reaction dynamics and spectroscopy, beyond the rather simple proof-of-concept applications that so far have been developed. demonstrating a new generation of quantum electro-dynamics (cq-ed) platforms, in conjunction with quantum algorithms and fundamental studies of quantum reaction dynamics, has the potential to change the landscape of quantum simulations and lead to significant advances in chemistry with impact on other fields ranging from biology to materials science to engineering. partnerships with the stern college for women at yeshiva university, the yale pathways summer scholars program, and programs at purdue and the university of michigan will be developed

to specifically establish an ecosystem for development of a well-trained workforce in quantum information science and in the modeling of molecular systems with quantum devices. the main goal of the cq-d-mqd is to investigate chemical processes by using modular 3d circuit quantum electro-dynamics (cqed) platforms that can enable efficient realizations of molecular problems at the hardware level. an example of the type of quantum dynamical processes to be studied with the proposed quantum computing modules is the dynamics of photoisomerization that initiates the process of vision in vertebrates, involving non-adiabatic quantum dynamics at a conical intersection of potential energy surfaces. thus, the cq-d-mqd will design bosonic modular circuits described by potential energy surfaces that directly map the corresponding molecular hamiltonians of interest, thereby enabling quantum simulations with fundamentally new and potentially very efficient quantum devices. the cq-d-mqd will embrace a climate of inclusion and **\*\*diversity\*\*** so that underrepresented minorities and women are included in the interdisciplinary, team-based research. specific goals for phase i include (i) the design of modular 3d circuit quantum electro-dynamics (cqed) platforms for molecular quantum dynamics simulations, (ii) development of algorithms for quantum simulations and quantum computing on the new cqed platforms, and (iii) applications of the developed bosonic modular devices and algorithms to simulations of photo-induced quantum reaction dynamics, vibronic many-body systems; and quantum chemical dynamics in the condensed phase. the cq-d-mqd research and training program will establish an ecosystem with emphasis on recruitment and retention of female scientists and other members of underrepresented groups to advance the frontiers of knowledge in this burgeoning field and to train the next-generation workforce. the scientific and technological outcomes have the potential to be transformative for the quantum simulation of chemical systems and have the potential to out-perform conventional quantum computing platforms and find application across a wide range of molecular systems and quantum phenomena. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: CCI Phase 1: NSF Center for Quantum Electrodynamics for Selective Transformations (QuEST)

Awardee: University of Rochester

Amount: \$1,800,000.00

Abstract: the nsf center for quantum electrodynamics for selective transformations (quest) is supported by the centers for chemical innovation (cci) program of the division of chemistry. quest is directed by todd krauss at the university of rochester, with a team that includes pengfei huo, william jones and nick vamivakas all from the university of rochester, jillian dempsey at the university of north carolina-chapel hill, nicolas large and zachary tonzetich from the university of texas-san antonio, teri odom from northwestern university and daniel weix from the university of wisconsin-madison. the development of better drugs to treat diseases, new materials that are both affordable and sustainable, and new ways to harness renewable energy all depend upon the synthesis of new molecules. when making new molecules, chemists are generally bound by a well-established set of "rules" for how a given molecule will and will not react. a limited number of tools exist to tune the result of a chemical synthesis, such as by varying the temperature, shining light on the reaction, or using a metal catalyst. however, the outcomes of a chemical reaction are largely pre-determined by the fundamental nature of the reacting molecules themselves. the goal of quest is to discover a new tool that will allow the development of new chemical reactions that are not currently possible. quest will do this by performing chemical reactions inside an optical cavity. in an optical cavity, light is best described as consisting of discrete quanta called photons. when such quantum-light from inside the cavity strongly interacts with the reactant molecules in a chemical reaction, the molecules are fundamentally altered in a manner that should unlock new types of chemical reactions. the ability to direct the outcomes of chemical reactions by simply changing properties of light delivered to the system represents a completely new way to tune a particular chemical synthesis, which, in turn, has the potential to transform approaches to chemical synthesis

and have broad benefits to society. quest will also train future leaders in the field, ensuring that they are well-prepared to communicate the excitement of quantum science applied to chemistry to a broad audience, and striving to build a cohort of developing quantum chemistry researchers that is truly diverse. the cci phase i nsf center for quantum electrodynamics for selective transformations aims to discover uniquely selective chemical functionalizations that are enabled by the strong interaction of matter and the quantum light of an optical cavity. quest is exploring a fundamentally new tool for the development of selective organic chemistry by utilizing optical cavity polaritons, hybrid light-matter quasiparticles, in a manner similar to chemical catalysts. quest brings together methods and approaches from across organic, inorganic, materials, theoretical, and physical chemistry as well as quantum optics. quest aims to establish a clear understanding of how polaritons influence properties of molecules relevant for chemistry--such as potential energy surfaces--and develop effective methods to create polaritons for a broad array of molecules in solution. model chemical reactions in phase i have been chosen to test the fundamental mechanism and basic principles of polariton chemistry. in addition to rigorous scientific training, quest will instruct students in best practices for bringing quantum-chemical science to a broad audience. efforts will be directed toward increasing **\*\*diversity\*\*** in the scientific pipeline through science experiences for underrepresented undergraduate students, as well as translating quest science into high-school laboratory activities, social media dialogues, and portable museum exhibits appropriate for all ages. this cci presents a bold vision for facilitating the growth of an entirely new and emerging field: using quantum electrodynamics principles to enable selective chemistry. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Recrafting Computer Science: Fiber Crafting as Computational Thinking

Awardee: University of California-Irvine

Amount: \$1,750,000.00

Abstract: this project aims to serve the national interest by paving the way to creating a technical workforce that is able to function effectively in highly collaborative, diverse environments. enhanced ability to nurture these skills and abilities will occur through development of measurement instruments, a novel curriculum, and research into the impacts of the curriculum. the project seeks to align with the ehr core research (ecr) program's intent by reflecting the interdisciplinarity of computational thinking (ct) and encouraging critical reflection with respect to the historical role of women and people of color in computer science (cs) and robotics. this project moves the traditional cs curriculum beyond the screen and back to its tangible roots to support learning, collaboration, and participation in cs. in this project, the newly crafted cs curriculum will engage undergraduates in the construction, programming, and use of a robotic loom, foregrounding the inherently interdisciplinary nature of ct in a formal cs curriculum. the project activities expect to broaden participation and collaboration in cs and stem, redefining what counts as a valuable learning activity in cs education. grounded in the learning sciences and embodied cognition, this project will further the development of interdisciplinarity and address key challenges to **\*\*diversity\*\*** in computing. the project activities will interweave iterative design-based research with periodic experimental research experiments to test the efficacy of the robotic loom designs and course materials for undergraduate learning of interdisciplinarity and collaborative computing. to ensure that the proposed designs effectively complement curricular and practical realities, the project team will consult with an advisory board, the undergraduates, and the participating institution's curriculum advisory boards to inform design and development throughout the project period. this project is supported by the ecr program, which supports work that advances fundamental research on stem learning and learning environments, broadening participation in stem, and stem workforce development. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Strategic Course-based Adaptations of an Ecological Belonging Intervention to Broaden Participation in Engineering at Scale

Awardee: University of Pittsburgh

Amount: \$1,731,741.00

Abstract: this project aims to serve the national interest by increasing the number and **\*\*diversity\*\*** of engineers produced in the united states. science overall has made great progress in increasing the participation of women. however, engineering has made no overall progress in the last 20 years, with women continuing to earn only 20% of engineering bachelor's degrees each year. improving retention in the first two years of engineering programs is important in addressing ongoing attrition. in particular, engineering will become more inclusive when the concerns that many students have about feeling alone in thinking they are incapable of mastering the course's content are addressed. in this project, short interventions will be implemented. these interventions are intended to reveal to students that most of the students in their class have these same concerns, that previous students just like them with similar concerns have successfully completed this coursework, and that their instructor believes they are capable of succeeding. prior research by the project team using the intervention in first-year courses has shown that these interventions can entirely eliminate course retention differences by gender as well as by race/ethnicity. a new method for customizing this intervention will be developed, tested, and further improved so that it can have similar strong benefits in different courses and at different universities. simple interventions that can be easily and scientifically customized to many contexts may have potential for significantly improving engineering outcomes across the united states. this project uses an ecological-belonging intervention approach that only requires a one-class or one-recitation session to implement and has been shown to erase long-standing achievement gaps by gender and race/ethnicity in several introductory stem courses. however, while simple, the intervention cannot involve a fixed script for different university and course contexts. rather, the content of the intervention needs to be customized to the local

context in order to address the specific concerns students have in that specific context. this project brings a highly interdisciplinary team across three strategically-selected universities with the goal of developing an approach to identify which 1st and 2nd year courses need this intervention, reveal student concerns in that course, adapt the intervention to address those concerns, and address other pragmatic constraints of how that course is taught. this systematic approach also includes processes for onboarding all the instructors of the given course. in answering a set of seven core research questions, the project intends to expand knowledge about 1) where (on which outcome variables), when (in which contexts, for which students), and why the ecological belonging intervention has positive effects, and 2) the extent to which this intervention on its own has measurable impacts on the overall problem of representation in the larger challenge of representation within the large engineering pathways that have struggled with representation. this kind of foundational knowledge is critical to making decisions about when to apply the intervention as well as providing important insights into how to apply the intervention. the nsf iuse: ehr program supports research and development projects to improve the effectiveness of stem education for all students. through the institutional and community transformation track, the program supports efforts to transform and improve stem education across institutions of higher education and disciplinary communities. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Improving Engineering Student Engagement, Self-Efficacy, Diversity Awareness, and Retention using Visualization and Virtual/Augmented Reality Technologies

Awardee: Georgia Tech Research Corporation

Amount: \$1,700,000.00

Abstract: this project serves the national interest by creating visualization and augmented/virtual reality (ar/vr) education modules in architectural engineering and construction (aec) courses that will help improve students' persistence in the program, self-confidence, and **\*\*diversity\*\*** awareness. students will work on real world projects in teams using the visualization and interactive ar/vr modules. social and technical interactions between students will be facilitated using virtual spaces that simulate physical meeting rooms in which students can share engineering artifacts. student learning will be supported with an interactive building environment, interactive exercises in a 3d virtual environment, and embedded audio/videos that provide feedback on student design decisions. students will visualize themselves as aec professionals and increase their self-efficacy starting in

k-12 or community college contexts as well as in the first year of their degree program. more advanced real-life engineering experiences will continue to reinforce self-efficacy and engagement in engineering throughout the aec curriculum. this collaboration between a research-intensive institution, university of nebraska-lincoln, and an hbcu, tennessee state university, will provide an opportunity for students to interact with other students from diverse backgrounds and produce valuable insights on the effectiveness of the education modules with different audiences. a virtual workshop series will be used to support the adoption of the modules by other aec programs, other engineering disciplines, and high school teachers. three education modules will be developed and implemented in courses at the collaborating institutions. an introductory module will be used for outreach to k-12 and community colleges to generate interest in aec fields. the remaining modules will be used for first and second-year aec students in existing courses. the design of the modules is informed by the model of domain learning theoretical framework including its constructs of stages of learning and phases of interest. modules will be developed with attention to the learning objectives of the courses and the level of aec curriculum that is being targeted. the project seeks to answer the following overarching research questions: 1) how does a module impact students' engagement, self-efficacy, and \*\*diversity\*\* awareness? 2) how do enrollment, retention, and graduation rates change as modules are introduced into the curriculum? and 3) how do the findings to the first two questions vary by institution? each module will provide the basis for a multi-case study where the institutional context defines each case. rich case descriptions and cross-case analysis will guide improvements to the module, highlight module transferability barriers and affordances, and enable interpretation of findings based on data from survey instruments and interviews. this project will advance knowledge about the impact of ar/vr-based learning modules in stem teaching and learning. the nsf iuse: ehr program supports research and development projects to improve the effectiveness of stem education for all students. through the engaged student learning track, the program supports the creation, exploration, and implementation of promising practices and tools. this award reflects nsf's statutory mission and has been deemed worthy of support through

evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Digitization TCN: Collaborative Research: Bringing Asia to digital life: mobilizing underrepresented Asian herbarium collections in the US to propel biodiversity discovery

Awardee: Harvard University

Amount: \$1,632,344.00

Abstract: asia is the largest continent on earth, and includes the world?s tallest mountains, lowest landscapes, and habitats ranging from arctic tundra to tropical rainforests and mangroves to deserts. the plants of this region are incredibly diverse in their identities and functions. more than one-third of

the world's 350,000 plant species grow in asia and include tiny alpine cushion plants, medicinal herbs, ancient crops, and some of the planet's tallest rainforest trees. but documentation of this **diversity** remains inaccessible and research about it is difficult because most herbarium specimens of asian plants have not been digitized. the all asia thematic collections network (tcn) will mobilize online 15 million specimens of asian plants currently housed in the us and around the world. the project will especially focus on digitizing specimens from the unique and critically endangered **diversity** hotspots of southeast asia and the himalaya-hengduan region. these mobilized digital data will accelerate research to conserve endangered plant species and understand the interacting effects of evolution and global environmental change on plant species **diversity**. the project will apply state-of-the-art informatics tools and high-throughput digitization methods to efficiently and affordably digitize an unprecedented number of herbarium collections. this effort will connect and build long-lasting relationships among 25 large and small consortium institutions in the u.s., europe, and asia. the focal areas from which specimens will be digitized encompass five **diversity** hotspots that include ~20% of the world's vascular plant flora and historically spanned 3 million km<sup>2</sup> of primary vegetation that now covers less than 300,000 km<sup>2</sup>. fundamental **diversity** data for these **diversity** hotspots are lacking, along with the necessary baselines required to characterize species' identity, range, and responses to ongoing climatic change. the overall goals of the all asia tcn are to rapidly digitize herbarium specimens of asian plants to advance **diversity** discovery and provide critical baseline assessments essential for establishing floristic change in the anthropocene. the project will accomplish this by (1) digitizing 3 million asian vascular plant specimens from u.s. herbaria; (2) developing and applying novel informatics tools and high-throughput digitization methods to massively scale herbarium digitization; (3) aggregating and mobilizing the digitized records from the project with those by international partners in china, france, the netherlands, and russia to establish a single online all asia portal of ca. 15 million specimens; and (4) enhancing opportunities for early career learners in science, technology, engineering, and mathematics by stimulating synergies between

bio\*\*diversity\*\* and computer scientists who will use design thinking principles to create real-world informatics solutions to bio\*\*diversity\*\* challenges. to stimulate curiosity in plant \*\*diversity\*\* and botanical exploration among the general public, the consortium members will host several asia-themed notes from nature virtual expeditions to facilitate additional specimen digitization by citizen-scientists. digitized specimen data mobilized through this project will be shared and made available through idigbio.org. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: BEE: The Evolution of Fluctuation-Dependent Species Coexistence

Awardee: Williams College

Amount: \$1,616,701.00

Abstract: understanding how similar species coexist has been a central question in ecology since its inception. the question is important because species **diversity** is a defining characteristic of natural ecosystems. traditional answers to this question focus on how species differ in the types of resources they use in non-fluctuating environments. under this paradigm, evolution can facilitate species coexistence when it makes species less similar in their resource use. however, natural ecosystems are not constant, and there has been recent interest in understanding how temporal variation in the environment, and differences in how species respond to this variation, can lead to conditions that favor coexistence. while we know about these fluctuation-dependent mechanisms in theory, we know little about whether they can promote species coexistence in natural populations. we know even less about how evolution either facilitates or impedes such fluctuation-dependent mechanisms. this research attacks these questions by leveraging studies of experimental evolution in nature together with mathematical models and experiments in artificial streams. the research will engage 38 young scientists from diverse backgrounds per year in the young scientist training program. the young scientists gain research experience that is complemented by training in ecology, evolution, and statistics. the researchers will also engage the public through an online outreach website and will develop training in ecology and evolution through mobile gaming, social media, and teacher training modules based on this system. this work will provide a multipronged test of fluctuation-dependent coexistence mechanisms in natural communities and investigate how they evolve. in doing so, this work will synthesize ideas in ecology and evolutionary biology. this research takes advantage of the natural laboratory provided by the structure of stream communities in trinidad, west indies where fish communities consist of either trinidadian guppies and hart's killifish or hart's killifish by themselves. killifish-guppy communities are formed when guppies invade

communities with only killifish. prior research has shown that following these invasions, guppies and killifish rapidly evolve differences in their life histories and resource use. these streams are also highly seasonal with pronounced dry and wet seasons. do killifish and guppies respond differently to these seasonal fluctuations? are guppies adapted to dry season conditions and killifish to wet season conditions? if so, then this difference provides an avenue for the two species to coexist. this research will also address how important these fluctuation-dependent mechanisms are relative to traditional fluctuation-independent mechanisms and identify how these contributions change through the formation of the community. this research will leverage replicated experimental evolution studies in natural ecosystems with structured models, factorial experiments in artificial streams, and stable isotope work. at the same time, the mathematical models will provide a framework for linking theory on species coexistence with evolutionary theory. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: DISES: Toward resilient and adaptive community-driven management of groundwater dependent agricultural systems

Awardee: Virginia Polytechnic Institute and State University

Amount: \$1,611,722.00

Abstract: groundwater for irrigation is foundational to the viability of numerous us farming communities, as well as the national and global food supplies they support. yet, this natural resource is being overexploited in many areas, threatening the social and economic viability of those that depend on it. irrigators in western kansas and south-central colorado are developing community-level rules regulating groundwater use and management in an effort to preserve the aquifer and their livelihoods ? a novel experiment in self-governance of groundwater commons. the initial success of these self-governance regimes has prompted their rapid spread, facilitated by a

transfer of experience and rule design from one community to another, resulting in the adoption of relatively similar rules across the communities. however, questions remain regarding the long-term effectiveness, resilience, and adaptability of these similar self-governance regimes under shocks, such as drought or volatile commodity markets. this work will explore these questions and help groundwater dependent agriculture communities create more effective, resilient, and adaptive groundwater management strategies. the project team will strive to not only bring timely findings to a pressing societal need but also to train undergraduate and graduate students in interdisciplinary science so they are positioned to help solve the vexing sustainability issues that confront society. the project will provide an empirical basis for new theory explaining how individuals and institutions contribute to socio-environmental system effectiveness, resilience, and adaptability. specifically, the work will answer important, but understudied, questions related to the processes, dynamics, and vulnerabilities of groundwater self-governance regimes. the work will tightly integrate research in both natural and social sciences to advance theory on how the spread of self-governance arrangements, and their interplay with natural and social factors, collectively influence the sustainability and resilience of groundwater-dependent communities. foundational to the research plan is the convergence of social and environmental data that will underpin a novel integrated model representing complex, dynamic interactions and feedback between social (irrigators and institutions) and environmental (aquifer and land) realms. the overall goal is to develop new theory of how socio-environmental and institutional **\*\*diversity\*\*** (or lack thereof) determines the effectiveness, resilience, and adaptability of groundwater self-governance regimes under current conditions and in response to social and environmental change. achieving this goal will advance broader understanding and theory of common-pool resource management and chart paths forward for groundwater dependent agriculture communities. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: DISES: Between maintenance and transformation: a socio-environmental systems framework for restoration decision-making under climate change

Awardee: University of California-Davis

Amount: \$1,599,937.00

Abstract: this project will develop a framework for understanding the range of responses, and their potential drivers, in restoration decision-making under climate change. following an extreme event such as a drought, storm, or heat wave, restoration actions might seek to recover and maintain a historically representative state. alternately, restoration actions might seek transformation to a new state that is anticipated to be more robust to future extreme events with climate change. both outcomes represent adaptation to climate change, but with distinct management goals for the end state. therefore, by analyzing the drivers of restoration outcomes on a continuum from maintenance to transformation, this project will identify drivers of adaptive capacity to climate change framed in terms of concrete, actionable goals. in addition, by focusing on marine systems, this project will benefit society by informing active restoration efforts. with fishery declines and closures, public agencies, ngos, fishing organizations, and citizen groups are implementing novel restoration interventions. partnership with these entities throughout the project will account for community and management needs in project activities and inform time-sensitive management decisions. the project advances stem educational training at three institutions, and broadens the participation of groups historically underrepresented in science. this project will explore kelp forests off the california coast as a model system to evaluate environmental and social drivers influencing efforts at restoration. following a series of marine heat wave events, california kelp have recently experienced unprecedented decline, with associated increases in kelp-consuming urchins impeding kelp recovery. kelp declines are associated with declines in bio\*\*diversity\*\* as well as declines in recreational and commercial fisheries that are vital to the associated coastal communities. the goal of this project is to characterize the drivers of maintenance and transformation outcomes in different

socio-environmental system (ses) components and explore their interactions through three integrated approaches. first, empirical investigation will characterize the drivers of ecological, social, and institutional capacity to respond to extreme events with a combination of oceanographic analysis, ecological field studies, and interviews and a survey of resource users, other stakeholders, managers, and regulators. second, informed by this empirical characterization, a dynamically coupled ses model will explore how the achievement of identified management goals on the maintenance-transformation continuum depends on uncertainty in system components and the relative time scales of ecological recovery and social response. third, linking the ses model to governance network analysis will indicate how ses network configurations affect the ability to realize goals on the maintenance-transformation continuum in fragmented institutional contexts. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: DISES: Modeling interactions between community forest dynamics and local livelihoods amidst institutional changes

Awardee: Oregon State University

Amount: \$1,598,100.00

Abstract: regulators and forest managers have long looked for answers regarding which institutional arrangements best serve to balance rural development and forest conservation. one such arrangement, is community forestry where some forest care and management is handled by local communities. while community forestry can be an effective in conserving forests and enhancing rural livelihoods, studies also show that that success is variable. this project will identify the conditions that lead to positive community forestry outcomes. it will identify the situations and arrangements that lead to success, across vietnam, laos, and cambodia. this work important for governments and non-governmental organizations in the u.s., where forests under community management are

increasing in number. it will also be beneficial in low- and middle-income countries where communities manage over 25% of forests. this project will train two phd students and a postdoctoral fellow in data science and modeling. course materials will bring modeling exercises into the classroom. this project will investigate changes in community forestry arrangements on forest condition and livelihoods. it will examine the role of institutional variability and social and ecological conditions in moderating community forestry impacts. it will also study feedback that drive changes in social and ecological outcomes. the researchers will build spatial datasets on forest condition and change, livelihoods, and institutions across three countries in the mekong region. this will be done using satellite imagery, citizen science datasets, longitudinal national socio-economic datasets, and community forest spatial data. they will apply a statistical matching research design to test the hypotheses that community forestry is more likely to maintain and restore forest cover and bio\*\*diversity\*\*. the method will also explore the ability of community forestry to enhance livelihoods, and how these impacts will be moderated by institutional variability and baseline social and ecological conditions. they will collect site-level ecological and social data to validate and refine the resulting models and examine causal mechanisms leading to varied outcomes. finally, they will build models that recognize feedbacks between forest condition and livelihoods under community forestry. those models will be capable of predicting landscape and livelihood changes at various spatial and temporal scales under changing institutional drivers and ecological conditions. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: DISES: Cumulative effects of ecological and social stressors on the dynamics of integrated ranching-wildlife systems: drought, wolves, and human decision-makers

Awardee: Regents of the University of Idaho

Amount: \$1,597,830.00

Abstract: as environmental changes intensify around the world, both humans and wildlife face greater uncertainty and risk, threatening both human livelihoods and wildlife bio\*\*diversity\*\*. this research seeks to understand how multiple sources of stress impact humans, free-ranging livestock, and wildlife in shared rangelands in the western us. increasingly frequent and more severe droughts make plant forage for wild herbivores and cattle less predictable and abundant, even as the return of gray wolves to parts of the landscape increases predation risk. as a result, wildlife such as deer and elk, as well as free-ranging livestock, may be forced to trade off food and security, and ranchers grazing their cattle on public land may face more uncertainty. this research will assess (1) how drought and wolves interact to affect wild herbivores and free-ranging cattle distributions across the landscape, (2) how decision-makers respond to these two sources of stress, and (3) how information, provided via a new wildlife and plant forecasting application, is received and used by both ranchers and wildlife managers. the project will also increase public awareness of human and wildlife connections and interactions in rangeland ecosystems via a documentary film, as well as by training citizen scientists to classify camera-trapped images of rangeland wildlife. a diverse group of undergraduate and graduate students as well as a post-doctoral researcher will be trained over the course of this project. outcomes of this project include a better understanding of how climate and carnivore risks affect human decision-making, as well as how humans impact rangeland food webs via cattle stocking and wildlife removal, potentially leading to increased opportunities for coexistence between humans and wildlife in changing environments. ecological shifts brought about by climatic change can strongly interact with other sources of change, such as recolonizing large carnivores, to alter food web dynamics and potentially reduce ecosystem provisioning for humans. the uncertainty created by such interactions also challenges human decision-making. a critical gap exists in our knowledge of how climate change affects human-wildlife systems via wild food webs, and how natural resource decision-makers respond to such stress. we hypothesize that multiple environmental stressors (e.g., climate change and novel predators) will have complex and interactive effects on human-wildlife systems. effects will likely occur via trophic interactions among

predators, prey, domestic animals, and plants within shared food webs, potentially reducing the provisioning of humans from the shared ecosystem and human tolerance for predatory and competitive wildlife, and increasing uncertainty for natural resource decision-makers. there is a pressing need to advance models, tools and theory to (a) understand how multiple stressors interactively affect food webs in which humans and domestic animals are embedded, and (b) identify and quantify feedbacks among natural resource decision-makers and human-wildlife systems in response to multiple environmental stressors. such information would assist in identifying potential ?tipping points? in system resiliency and allow for better management of interacting wildland and agricultural systems. using a factorial design of study sites across combinations of wolf presence and drought in oregon and idaho, we will study rancher-wildlife-plant dynamics. data will stem from rancher surveys, wildlife camera grids, and ground-surveyed and remotely-sensed plant data. we will integrate social and ecological data into a structural equation modeling framework, which will drive ecological forecasts of predation and competition risk to livestock for ranchers and managers to use in future decision making. to understand natural resource manager decisions, which occur at larger spatial scales than rancher decisions, we will conduct a broad-scale analysis of the rangeland ses across the western us using publicly-available wildlife and social data and remotely-sensed environmental characteristics. by analyzing decision-making across these spatial scales, we anticipate being able to identify key feedbacks, emergent phenomena, and potential tipping points in resilience for the human and wildlife components of the rangeland ses. this project is jointly funded by the dynamics of integrated socio-environmental systems (dises) and the established program to stimulate competitive research (epscor). this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: MIM: The impact of the fungal microbiome in metal tolerance and soil biogeochemical transformations

Awardee: University of Houston

Amount: \$1,574,057.00

Abstract: some metals are essential nutrients for life, while some are non-essential or even harmful to living organisms. fungi and bacteria are microorganisms that often live in a close association and play a key role in transforming and detoxifying metals in the environment. in spite of this importance, there is relatively little understanding of how the interactions between bacteria and fungi influence the transformation and/or detoxification of metals. the goal of this project is to address this knowledge gap by identifying how fungal-bacterial interactions affect metal transformation. this will be achieved through a novel multidisciplinary research approach employing advanced, state-of-the-science analytical techniques. knowledge gained through this project will allow the engineered control of metal transformations for a wide range of applications in environmental cleanup, biorefining, production of nanoparticles, and other beneficial applications. successful completion of this research has strong potential to benefit society through improvements in environmental remediation and industrial manufacturing. this project will improve the nation's stem workforce by providing a unique training opportunity for student researchers that bridges diverse fields such as environmental engineering, microbiology, geochemistry, bioinformatics, and art. remediation of metal contamination is a major environmental challenge because, unlike many organic pollutants, metal species cannot be degraded and can only be extracted or biotransformed to less toxic forms. while past approaches to biotransform metals have focused primarily on single microorganisms, host-microbiome interactions have shown potential to biotransform surrounding environments and improve host resiliency. however, the mechanisms for metal biotransformation by microbial host-microbiome systems are largely unknown. the overall goal of this project is to

elucidate the rules of life that govern fungal microbiomes. this goal will be achieved through a specific focus on fungal microbiomes, which include a fungal host, endosymbionts (endobacteria), and symbionts (exobacteria that live extracellularly) as a model host-microbiome system. the specific research objectives of this project designed to achieve the goal are to: understand the effects of metals and metalloids on the **\*\*diversity\*\*** and transmission of fungal microbiomes (facultative and obligatory); and determine the role of fungal microbiomes in metal tolerance by mediating the uptake, transformation, and sorption of metal ions, nanoparticles, or other metal species. a deeply integrated multidisciplinary approach will be used to investigate physiological, genetic/genomic, and metabolic processes that govern the structure and function of fungal microbiomes in the presence of metals. this will be achieved using novel state-of-the-science isotope probing, advanced microscopy, spectroscopy, and integrated genomics, transcriptomics, and metallomics to elucidate how the microbiome influences the metabolic activity of the host towards metal ions. successful completion of this research has strong potential to identify new genes and/or pathways for metal tolerance and biotransformation, as well as expand our mechanistic understanding of the structure and function of fungal microbiomes in nature. this knowledge has strong potential to benefit society by facilitating applications in remediation, water treatment, electronics manufacturing, antimicrobial production, medicine, and related fields. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: FW-HTF-R: Race, Gender and Class Equity in the Future of Work: Automation for the Artisanal Economy

Awardee: Regents of the University of Michigan - Ann Arbor

Amount: \$1,566,000.00

Abstract: ai is poised to eliminate millions of jobs, from finance to truck driving. but artisanal products

and labor?such as handmade textiles, furnishings, adornments, foods, and repair shops?are valued precisely because of their human origins, and thus have some inherent ?immunity? from ai job loss. and they are often more enjoyable. while many of the jobs ai can (and should) replace are dull or dangerous, artisanal labor is at the other end of the spectrum: some of the most satisfying professions possible. many artisans strive to be more environmentally sustainable, using ?green" supply chains and techniques. but most importantly, artisanal business is one of the few sectors where ownership can be found at the grassroots. from beauty salons to auto detailing; ethnic foods to repair shops, we find that groups underrepresented by race (black, native, latinx); by gender (women) and by socioeconomic status (poor people of all ethnicities) are more likely to own non-employee businesses than other companies. new forms of automation--ai, robotics, and others--are now being developed for mass-production contexts. this research will work to adapt these new forms of automation for use by small non-employee businesses, in order to enhance production rates, repertoires, product quality and sustainability for this more diverse demographic. it will work toward enhancing wealth equity through a diverse ecosystem of artisanal enterprises, utilizing innovations in information technology to foster collaborations in supply chains, marketing and other dimensions.      this project will develop new theory and knowledge addressing 2 primary research questions. (1) how can ai, robotics and related automation technologies enhance equity for underrepresented groups by enhancing the capabilities of artisanal production and services? (2) how can collaborative innovation with grassroots participants expand their niche to move us closer to a circular economy; one that empowers their labor value? these research questions will be investigated using a four step approach. (1) develop practical applications for immediate use with artisan collaborators in detroit, focusing on digital fabrication. prior studies show that many artisanal practices include computational thinking in their approach (iteration in weaving for example). by simulating these ?heritage algorithms? we can test strategies to enable the blending of beloved cultural traditions with digital fabrication, and from there develop training opportunities and resources for new products, skills, and innovation. the hypothesis is that, contrary to mass production

scenarios, there is no single optimum for human-machine task allocation in the artisanal domain. instead, we hypothesize a wide **\*\*diversity\*\*** of strategies that are optimal for different contexts. (2) utilize feedback from these experiences to run small scale experiments in the future of work with artisanal economic networks, such as platform cooperatives and the use of ai in guiding sustainable consumption and supply chains. (3) design, develop, and evaluate a community asset mapping database for tracking changes in inter-organizational alliances, supply chains, entrepreneurship incubation, and other elements of the potential artisanal economy network. the intention is to enable the evaluation of a broader vision for how automation-empowered artisanal labor could aid the general transformation to a circular, non-extractive economy. (4) expand the research context to include artisanal groups across the nation. this will address the generalizability of the project's emerging theoretical framework, and support dissemination of its open-source technologies. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Faculty Research and Education Development Program II

Awardee: American Society For Cell Biology

Amount: \$1,534,605.00

Abstract: over the past 40 years, there has been an expansion in our understanding of the world through a scientific lens; however, there is a recognition that we are not fully engaging our scientific talent pool. the faculty research and educational development (fred) program seeks to broaden participation through mentored relationships for postdoctoral scholars and junior faculty members, many of whom are from groups historically and currently underrepresented in the sciences. in addition, given the impact that minority-serving institutions (msis) have on broadening participation in the sciences, the fred program also encourages the participation of faculty members at msis. fred was developed by the minorities affairs committee (mac), a standing committee of the american

society for cell biology (ascb) tasked with addressing issues of historically underrepresented cell biologists. specifically, the fred program matches junior scientists with senior mentors who have demonstrated funding success at research-intensive institutions for a long-term mentoring relationship focused on the preparation and submission of a research or educational grant to an external funding agency. over the past 7 years, 46 historically underrepresented scholars or junior faculty at minority-serving institutions (msis) have participated in the fred program with a funding success rate of 62% and 27% of them receiving more than one award. the fred program is organized with participants attending a career development workshop, participating in a mentored relationship to prepare a proposal, and a mock review panel at the annual ascb conference to review the proposal and provide the mentee comments before submission to a funding agency. the fred-ii program will continue with the mission of improving grant funding success and career development for junior faculty and will implement improved support pathways for fred mentees who are not successful in their first proposal submission and will look to resubmit their proposal. it will continue with the successful implementation of a summer workshop to be held primarily near or at msis. in addition, in alignment with national imperatives in increasing **\*\*diversity\*\*** among faculty, the program will create a pre-fred workshop designed to engage potential fred mentees to develop an applicant pool for future fred workshops. the fred-ii program will continue to support and develop the next generation of research scientists and leaders and broaden their participation in science. the fred-ii program will support junior faculty and postdoctoral scholars through a structured mentored relationship with a senior faculty member. the year-long program will include a summer career development workshop for all fred mentees, monthly mentor-mentee meetings with in-person reciprocal visits to mentor-mentees campuses. fred mentees will develop a proposal with support from their selected mentor and participate in a winter mock review panel hosted at the annual ascb meeting. meetings and reciprocal visits will continue until a proposal is submitted to a federal agency. fred-ii will also include continued participation and additional support for fred mentees who are unsuccessful in securing funding on their first attempt. the fred-ii program will also include

evaluative efforts to inform the leadership of the effectiveness of the program and areas where improvements are needed. overall, the fred-ii program promotes the careers of underrepresented junior faculty and postdoctoral scholars at research institutions and msis through mentorship and grant success. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Belmont Forum Collaborative Research: Abandonment and rebound: Societal views on landscape- and land-use change and their impacts on water and soils (ABRESO)

Awardee: Pennsylvania State Univ University Park

Amount: \$1,531,825.00

Abstract: this award provides support to u.s. researchers participating in a project competitively selected by a 9-country initiative on global change research through the belmont forum. the belmont forum is a consortium of research funding organizations representing over 55 countries focused on support for transdisciplinary approaches to global environmental change challenges and opportunities. it aims to accelerate delivery of the international research most urgently needed to remove critical barriers to sustainability by aligning and mobilizing international resources. each partner country provides funding for their researchers within a consortium to alleviate the need for funds to cross international borders. this approach facilitates effective leveraging of national resources to support excellent research on topics of global relevance best tackled through a multinational approach, recognizing that global challenges need global solutions. this award provides support for the u.s. researchers to cooperate in consortia that consist of partners from at least three of the participating countries. the research teams will work to identify sustainable pathways to help alleviate the increasing and unprecedented pressure on the natural resources that interact to provide sustainable life support systems and essential benefits to societies such as food production and water quality and quantity. the impacts of changes in land management and

urbanization will be evaluated to develop sustainable soils and groundwater management options that will help create and maintain sustainable terrestrial ecosystems. the project seeks to develop a global transdisciplinary platform for understanding the impacts of land abandonment on sustainability of soil and water resources. land abandonment and subsequent land use or land cover change can have profound implications for water resources, as the changing fabric of the critical zone dictates changes in infiltration, runoff, and the delivery of sediment and nitrogen to groundwater and surface waters. the project team will describe social and natural forcing functions that drive land abandonment and subsequent land use change; and quantify impacts on water quality due to this abandonment. the team will also identify gaps in understanding of the impacts and those perceived by stakeholders so that land use change can be better understood and modeled. the team will use this information to develop a modeling framework to assess sustainability of various land use and land abandonment scenarios in the context of the intergovernmental science-policy platform on bio\*\*diversity\*\* and ecosystem services. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Particles, Strings and Gravity in a Dynamical Universe

Awardee: University of California-Berkeley

Amount: \$1,507,000.00

Abstract: this award funds the research activities of professors mina aganagic, raphael bousso, and petr horava at the university of california at berkeley. in the first two decades of this century, we have witnessed dramatic progress in our understanding of the fundamental laws of the universe from the shortest to the largest scales, firmly based on the principles of quantum mechanics (which describes the subatomic world) and general relativity (which describes gravitational forces acting at large distance scales). while string theory may represent the dominant paradigm for unifying these

two principles, many important puzzles and open questions still remain. professors aganagic, bousso, and horava will attempt to provide answers to some of these open questions and puzzles, with the goal of deepening our understanding of the quantum-mechanical universe. specifically, these professors will investigate the properties of quantum-mechanical theories of gravity by using the newly found connection between such theories and the rapidly developing interdisciplinary field of science known as "quantum information theory", as well as by using more traditional methods that have been successful in describing all the non-gravitational forces in nature. the results of this research are expected to have implications for the puzzles associated with the quantum-mechanical behavior of black holes, possible short-distance generalizations of einstein's general theory of relativity, and the structure of the evolving universe at largest distances. in addition, professors aganagic, bousso, and horava will work on the relations of string theory and quantum gravity to pure mathematics. such research is expected to have a broad impact not only in particle physics and cosmology, but also in neighboring areas of physics and beyond. this research thereby advances the national interest by promoting the progress of science in its most fundamental form. the universal nature of this research also serves as an excellent vehicle for supporting the education of young researchers (students and postdoctoral scholars), and provides a natural platform for further increasing **\*\*diversity\*\*** and inclusion in science. more specifically, professor aganagic will develop her program of categorifying quantum knot invariants using little string theory in six dimensions and its low-energy limit known as theory x. she will also pursue categorification of chern-simons gauge theory on general three-manifolds. professor bousso will expand the ads/cft holographic dictionary by studying the kink transform. he will examine the euclidean path integral in semiclassical quantum gravity, using his recently proposed gravity/ensemble duality. in addition, he will attempt to strengthen the quantum focussing condition, and will revisit the notorious measure problem in the landscape cosmology of string theory. professor horava will apply nonrelativistic completions of relativistic quantum field theories to the puzzles of technical naturalness (such as the higgs mass hierarchy problem and the cosmological constant problem). he will work to identify new classes of

short-distance completions of relativistic supersymmetric yang-mills gauge theories in higher dimensions, using nonrelativistic aristotelian supersymmetry at short distances. he will use the recently discovered topological nonrelativistic quantum gravity of perelman's ricci flow to study puzzles of quantum gravity, such as topology-changing transitions and quantum completeness. he will study string theory in its covariant formulation in the novel regime far from equilibrium, as described by the schwinger-keldysh formalism. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: RECODE: Functional characterization of human skin organoids

Awardee: University of California-Irvine

Amount: \$1,500,000.00

Abstract: do skin organoid cultures, essentially growing human skin in a dish, accurately reflect how normal skin develops? this project aims to use cutting-edge technologies in biology, engineering, and mathematics to define how human epidermal stem cells differentiate at the single cell level. the major benefits will reveal new insights into developmental biology, adult homeostasis, disease modeling, and provide a platform for preclinical drug testing. new computational tools for analyzing cells at the single cell level will be developed by integrating dynamic modeling with the cell's spatial position to reconstruct how cells transition from one state to another, how they communicate, and how cells interact at the single cell to tissue levels. the broader societal impacts include developing an interdisciplinary training program to enhance research, **\*\*diversity\*\***, and outreach at the interface between mathematical, physical, and biological sciences. a major challenge in organoid biology is defining stem cell states and their interactions that lead to differentiation of the tissue. the goal of this recode project is to define human skin equivalent organoids to address how to faithfully reproduce the differentiation of human epidermal stem cells and generate fully functioning in vitro

stratified human skin. this project will integrate single cell rna-sequencing with spatial imaging data using new mathematical and computational tools applied to primary human epithelial progenitors undergoing active differentiation on engineered substrates in an in vitro organoid culture. novel computational tools will be developed to connect dynamic spatial models with novel data analytics and these tools will reveal transition cell states, cell-cell communication, and cell-cell spatial maps ? three important but underexplored areas in cell fate analysis. the new multiscale models will define when, where, and how human keratinocytes acquire their fates and robustly differentiate to establish stratified epidermis. this recode award is co-funded by the physiological and structural systems cluster in the division of integrative organismal systems and the engineering biology and health cluster in the division of chemical, bioengineering, environmental, and transport systems. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Recognizing Science Scholars' Potential through Access and Engagement

Awardee: Saint Paul College-A community & Technical College

Amount: \$1,500,000.00

Abstract: this project will contribute to the national need for well-educated scientists, mathematicians, engineers, and technicians by supporting the retention and graduation of high-achieving, low- income students with demonstrated financial need at saint paul college, an urban community and technical college with a large population of students from populations traditionally underrepresented in stem. over its six-year duration, this project will fund scholarships to approximately 80 unique full and part time students who are pursuing associates degrees primarily in science and engineering technology. students will be awarded up to \$16,000 over up to eight semesters, including summer. the ?science scholar? students participate in relationship-building co-curricular activities: faculty and peer mentoring, science-related campus events and

service-learning activities, and a semester long undergraduate research project. the science and engineering technology a.s. program encourages transfer or entrance to the workforce, so students can work while continuing towards their b.s, degree. the educational research on the effect of the project on student success, experience, and career choice will help inform science education and co-curricular engagement at many two-year schools with a diverse student pool. the overall goal of this project is to increase stem degree completion of low-income, high-achieving undergraduates with demonstrated financial need. the first major objective is to recruit and award scholarships to these students, using internal recruitment strategies and partnerships with area high schools. the project will also increase participation of students from groups underrepresented in stem due to the **\*\*diversity\*\*** in the pool of potential students. the recruitment events at partner high schools will expose high school students to stem career opportunities and solidify a pipeline of students coming to the two-year institution. the scholarship amount is approximately the cost of tuition and fees for a full-time student, so the first expected outcome is the scholarships will increase the number of students completing an a.s. degree. the second objective is to add the relationship-building, co-curricular, high impact practices (hips) to the scholarship program. previous research, mainly performed at universities, suggests scholarships combined with support services increased student success and promote access. hence, an expected second outcome is an increase in retention and student success. the third objective is to perform and disseminate educational research on the effectiveness of the scholarship/hips on student success (course success, retention, and graduation/transfer), science attitudes, and career choice. a mixed- methods approach will link survey responses to student records, and the focus groups will give context to the quantitative data. further, there is a notable gap of applied science education research coming from two-year institutions. the dissemination of the project findings, the third project outcome, will play a small role in closing this gap. this project is funded by nsf's scholarships in science, technology, engineering, and mathematics program, which seeks to increase the number of low-income academically talented students with demonstrated financial need who earn degrees in stem fields. it also aims to

improve the education of future stem workers, and to generate knowledge about academic success, retention, transfer, graduation, and academic/career pathways of low-income students. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: SCC-IRG Track 2: Toxic-Free Footprints to Improve Community Health against Respiratory Hazards

Awardee: Northeastern University

Amount: \$1,500,000.00

Abstract: fifty years after the passing of the clean air act in the u.s., nearly half of the nation's population is estimated to live with and breathe polluted air in 2020. the recent acceleration in the number and intensity of wildfires driven by climate change and the devastating covid-19 pandemic have made air pollution effects on public health an even more heightened concern. this smart and connected communities project builds and enhances technological, economic, political, and social infrastructures in vulnerable communities to better sense and monitor air quality, prevent exposure to respiratory hazards, and raise awareness of and battle misinformation on air quality. the research aims to build smart and connected toxic-free communities, which resonates with nsf's mission ?to advance the national health, prosperity, and welfare.? the research team collaborates with local grass-root organizations, communities, research centers, and planning agencies in two communities, roxbury, boston, ma and st. john the baptist parish, la. the new technological approaches and air quality data generated by the project along with the deep community engagement will potentially influence and enhance policies and benefit underserved communities with more equitable access to a healthy environment. in this research project, the research team (1) develops data-driven approaches to seamlessly link human mobility (i.e., a person's footprints within and beyond the residential place) and respiratory hazards measured by air quality monitors;

(2) designs real-time ai technologies to connect information and communities that support both network-based interventions; and (3) deploys the methodology in two representative local communities characterized with minority and **\*\*diversity\*\*** both burdened by air pollution. the research focuses on volatile organic compounds (vocs) and particulate matter (e.g., pm2.5) for their known health impacts of causing lung cancers and cardiovascular and respiratory diseases. the key deliverables of work include: (1) a data-driven and real-time ai-based framework that links multi-model data streams (e.g., geolocations, air quality, social networks, etc.) to quantify and predict air pollution exposures associated with human footprints; (2) social network-based interventions strategies developed interactively with and tested by two communities burdened by air pollution (roxbury, boston, ma and st. john parish, new orleans, la); and (3) real-time ai-powered mobile application (app), toxic-free life, for mainstream smartphones that allows real-time estimations of air exposure and supports network-based interventions. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Alternate Pathways to Excellence: Engineering a Transfer-Friendly Experience

Awardee: University of St. Thomas

Amount: \$1,499,997.00

Abstract: this project will contribute to the national need for well-educated scientists, mathematicians, engineers, and technicians by supporting the retention and graduation of high-achieving, low-income students with demonstrated financial need at the university of st. thomas (ust). located in the twin cities, mn, ust is a designated "military friendly school" as well as a recognized "first-gen forward institution" and is known for its high rates of retention (87%) and graduation in four years (68%). over its six-year duration, this project will fund scholarships to 31 unique full-time students, including transfer students, who are pursuing bachelor's degrees in civil,

computer, electrical, or mechanical engineering. low-income, academically talented engineering students who have demonstrated financial need will receive scholarships for up to three years. the alternate pathways to excellence (apex) project will increase the number of engineering transfer graduates by leveraging innovative mentoring practices, advancing engineering-focused **\*\*diversity\*\***, equity, and inclusion efforts, and leveraging ust's partnerships with five local community colleges. the project team also expects to build strong connections with local employers to help achieve the project's goals. support activities for scholars will include a new summer bridge course, monthly seminars to boost skills, and faculty, peer, and industry mentoring. through the apex project, ust will accelerate the engineering department's efforts to advance an inclusive culture by addressing structural limitations that are common in engineering program curriculum, teaching practices, and recruitment efforts. these strategies will have significance for engineering education broadly, and for supporting and retaining transfer students. as a result, the apex project will produce diverse, well-qualified engineers who will meaningfully contribute to fueling innovation in the twin cities region.

to increase stem degree completion of low-income, high-achieving undergraduate transfer engineering students, including students traditionally underrepresented in their participation in stem courses of study and first-generation students, the project leadership will pursue three specific aims. first is to partner with five community colleges to recruit transfer students. second is to retain 90% of scholars each year and graduate 90% of all scholars within 3 years. third is to support at least 95% of graduates to become employed in engineering or enrolled in a graduate degree program within 4 months of degree attainment. apex is grounded in institutional research and knowledge from prior step awards, as well as an understanding of transfer students' unique needs for retention support, including needs to identify scientific mentors and establish a sense of belonging. community college engineering students have been shown to benefit from tailored academic and personal supports that address their unique challenges. however, more investigation is needed to understand how specific interventions such as mentoring, a summer bridge course, and enhanced internships or research can improve engineering transfer student retention. in addition,

there is limited research on the extent to which \*\*diversity\*\*, equity, and inclusion programming for engineering faculty and students creates a scientific community that supports transfer student retention. ust will evaluate and advance understanding of the extent to which these targeted activities contribute to retaining transfer students. results will be disseminated via the keen national conference and website, asee's two-year college division, and submissions to peer-reviewed publications such as the journal of engineering education. this project is funded by nsf's scholarships in science, technology, engineering, and mathematics (stem) program, which seeks to increase the number of low-income academically talented students with demonstrated financial need who earn degrees in stem fields. it also aims to improve the education of future stem workers, and to generate knowledge about academic success, retention, transfer, graduation, and academic/career pathways of low-income students. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Biology Opportunities and Scholarships for Success II

Awardee: University of West Alabama

Amount: \$1,499,857.00

Abstract: this project will contribute to the national need for well-educated scientists, mathematicians, engineers, and technicians by supporting the retention and graduation of high-achieving, low-income students with demonstrated financial need at the university of west alabama (uwa). located in rural alabama, uwa is designated as a predominately black institution (pbi) and predominately undergraduate institution (pui). building on the experiences and lessons learned from a prior s-stem award, this project will fund scholarships to 30 unique full-time students pursuing bachelor's degrees in biological and environmental sciences. it will also expand student support services including a summer boot camp to aid with the transition to college life, training to

improve students' study strategies, monitoring students' well-being, and improving their communication skills. scholars will also be involved in peer- and faculty-mentoring, research opportunities, presentations at professional conferences, and participation in field trips. the project plans to increase retention and graduation rates, monitor student success in obtaining jobs or entering graduate school, and measure the significance of the project's services and activities in helping students achieve their goals. the project will advance understanding of the role well-being assessments, metacognitive study strategies, and communication skills in increasing student retention and success. the knowledge generated from this project is of significance to uwa and many other similar higher education institutions. the overall goal of this project is to increase stem degree completion of low-income, high-achieving undergraduates with demonstrated financial need. the biology opportunities and scholarships for success ii project aims to increase participants' persistence in science, success in academic careers, and, ultimately, **diversity** in the scientific workforce. two specific goals serve as driving forces for the project. the first is to increase the enrollment and graduation rates of academically talented students majoring in biological and environmental sciences and improve student success in obtaining jobs or entering graduate programs. the second is to evaluate the role of student support services (boot camp, student's well-being, metacognitive study training, and enhancement of students' communication skills) in improving students' retention and graduation rates. the project will generate knowledge through a mixed methods quantitative and qualitative study that investigates the effectiveness of the project's support services. the work will help to fill a knowledge gap about how the student support services impact students' retention and overall success, particularly on minority students in rural settings. the project will disseminate the generated knowledge via articles in peer-reviewed journals and presentations at regional and national stem education-related conferences. this project is funded by nsf's scholarships in science, technology, engineering, and mathematics program, which seeks to increase the number of low-income academically talented students with demonstrated financial need who earn degrees in stem fields. it also aims to improve the education of future stem workers, and to

generate knowledge about academic success, retention, transfer, graduation, and academic/career pathways of low-income students. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: HDR DSC: AI across the statewide curriculum

Awardee: University of Florida

Amount: \$1,498,319.00

Abstract: artificial intelligence (ai) is reshaping the society we live in a profound manner. ai is changing how a nation protects its homeland and population, manages its natural resources and infrastructure, diagnoses and treats diseases, travel, communicates and creates artistic works, etc. ai has the potential to generate tremendous benefits for the society and people. however, the future ai workforce must represent the **\*\*diversity\*\*** of racial, ethnic, gender-identity and socioeconomic backgrounds reflective of the nation as a whole, otherwise, an ai-enabled future society could exacerbate existing disparities and benefit just a few, at the expense of too many. to address such a grand challenge, this dsc award is to train a diverse workforce capable of integrating ai equitably across a broad range of disciplines. the project provides unique ai training to students from any discipline using an approach that integrates classroom education in ai fundamentals, applications and ethics with real-world case studies and research experiences spanning the undergraduate curriculum with a focus on enhancing **\*\*diversity\*\***. by recruiting and retaining historically underrepresented minorities in ai-related education and research, this project helps ensure that a **\*\*diversity\*\*** of backgrounds and opinions are included at all levels of future ai developments and applications, so the ai-enabled society can broadly benefit everyone. to achieve the goal of educating a diverse next-generation ai workforce, this project develops a vertically-integrated curriculum in which students from outside traditional computer-science fields can learn ai-related concepts, skills and ai applications to address critical emerging problems in one's field. over 250 undergraduate fellowships will be created to help eliminate or lessen financial barriers to education. further, between a research university and a historically black college, a strategic partnership provides flexible avenues to engage diverse undergraduates in ai-related education and research. this project develops a core curriculum covering ai fundamentals, ethics and discipline-specific applications that can be deployed across traditional university disciplines and leverages distance-learning to enable students to participate on their own schedule from anywhere with internet. the award also provides unprecedented access to some of the most advanced computational resources in the world while maintaining the flexibility to adapt to a rapidly-changing

field by providing financial assistance supporting the development of new courses and undergraduate research in academic, industry and community studies. it is expected that this approach of integrating "ai across the curriculum" will equip all interested students to equitably engage ai in their chosen discipline. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Fostering Future Engineering Faculty Diversity by Building a Pipeline to Graduate Programs

Awardee: University of Massachusetts Lowell

Amount: \$1,495,564.00

Abstract: this project will contribute to the national need for well-educated scientists, mathematicians, engineers, and technicians by supporting the retention and graduation of high-achieving, low-income students with demonstrated financial need at the university of massachusetts lowell, a r2 public research university with a high percentage of first-generation undergraduate students. over its 6-year duration, this project will fund scholarships to 24 unique full-time students who will be supported for four years from their junior undergraduate year through the completion of a master's degree or completion of their qualifying exam within a ph.d. program. the goal of the project is to create a diverse and competitive pool of students who could become future faculty candidates in engineering by aiding them to explore their interest in these careers and supporting them to prepare and embark on these graduate education pathways. project activities include group-based mentoring meetings with internal and external faculty, safe space cohort building, job shadowing, individual graduate school application support, positive teaching and research experiences, a curriculum to cultivate pedagogical and content knowledge, and a mentorship program (entering research mentoring program; ermp) for first- and second-year graduate students. the project will also employ podcasting as a way to introduce high school

students to stem careers. this project has the potential to significantly increase the number of stem graduates from traditionally underrepresented populations in engineering at the graduate level, and strengthen the pipeline of highly qualified diverse candidates entering careers in higher education. another important broader impact is the project's strong potential to foster social justice educators with core personal and professional beliefs in **\*\*diversity\*\*** and inclusion, which help promote inclusive and equitable environment in higher education to retain a future generation of engineering students. the intellectual merit goal is to better understand the factors that motivate low-income, high-achieving, underrepresented engineering students to persist in the trajectory to engineering graduate programs and future faculty positions in higher education. the project plans to employ a variety of evidence-based interventions that have been used successfully to support students to achieve their career goals. the project will determine whether group-based mentoring and safe space cohort building contribute to low income, high achieving analyze the evaluation data collected from a teaching diverse populations course to advance knowledge about how to cultivate social justice educators. in addition, the project will explore the potential of podcasting as a way for scholars to self-express and explore their interest and confidence in pursuing a faculty career. lastly, the project will examine whether participation in ermp results in positive mentoring relationships, professional identity, research and academic skills, and confidence in pursuing faculty careers. results of this project will be disseminated via presentations at local and national conferences, publications in engineering education journals, a website featuring cohort activities, and podcast episodes targeted to high school students. this project is funded by nsf's scholarships in science, technology, engineering, and mathematics program, which seeks to increase the number of low-income academically talented students with demonstrated financial need who earn degrees in stem fields. it also aims to improve the education of future stem workers, and to generate knowledge about academic success, retention, transfer, graduation, and academic/career pathways of low-income students. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review

criteria.

Title: Dimensions US-China-South Africa: Establishing genetic, phylogenetic and functional mechanisms that shape microbiome diversity of polar and alpine soils

Awardee: Rutgers University New Brunswick

Amount: \$1,494,294.00

Abstract: microorganisms are the foundations of ecosystems and drive the biology and chemistry in soils, e.g. the conversion of soil organic matter into the greenhouse gases carbon dioxide and methane, as well as nitrogen and phosphorous compounds that can be used by plants. soil microbial community **\*\*diversity\*\*** maintains ecosystem stability and sustainability. understanding the ecology of these microorganisms is one of the most compelling scientific challenges. this project will focus on the microbial ecology of soil ecosystems in the arctic, antarctic, and tibetan plateau. these ?tri-polar? soils are chosen for study as they are disproportionately impacted by climate change and predicted to show increased microbial activity and enhanced turnover of soil organic matter in the future. while microbes excel at adapting to environmental change, the functional implications of microbial community transitions remain to be characterized. laboratory- and field-based approaches will identify microorganisms that are successful in these ?tri-polar? soil ecosystems and why, i.e., which bacterial species/strains are successful and what functional traits make them successful. understanding how soil ecosystems respond in these polar regions is critical for evaluating the controls of biogeochemical cycling and clarifying microbial feedbacks in a changing world. this project will assemble an international team and recruit young scholars to reflect a blend of expertise in microbiology, ecology and environmental sciences. research will be integrated with educational activities by involving samples and data into hands-on classroom training at the k-12, undergraduate, and graduate levels. this project will delineate mechanisms that lead to diverse soil microbial communities that are hallmarks of stable and sustainable soils. we lack predictive

understanding of mechanisms that regulate and maintain microbial bio\*\*diversity\*\* and how this relates to biogeochemically relevant microbial functions. integrative approaches are needed to identify the principles that shape and maintain this bio\*\*diversity\*\*. this project combines genetic, phylogenetic, and functional dimensions of bio\*\*diversity\*\* to probe factors that shape the "morass of \*\*diversity\*\*" of soil systems. the overarching hypothesis is that resource partitioning, selective predation, and temporal separation of activity each contribute to the success of particular bacterial strains/species in polar and alpine systems. the international research team will focus on testing these hypotheses in soils across arctic, antarctic and tibetan plateau habitats with the acidobacteria as a model microbial phylum for study. laboratory- and field-based approaches will be linked to describe the genetic, phylogenetic and functional \*\*diversity\*\* the acidobacteria, one of the most ubiquitous but elusive bacterial phyla found in terrestrial ecosystems around the globe. the study will identify their ecosystem functions in soils, their interactions with other microbes, their adaptations to environmental stress such as climate change, and will assess their in situ dynamics and activity. integration of these data will address which organisms compete for resources, avoid predation, and ultimately, occupy fundamentally distinct niches in these ecosystems. elucidating these equalizing/stabilizing mechanisms can begin to explain the tremendous bacterial \*\*diversity\*\* observed in soil microbiomes. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Improving Educational Outcomes at Two-Year Colleges through Mentorship, Support Services, and Equitable Classroom Practices

Awardee: College of the Canyons

Amount: \$1,493,379.00

Abstract: this project will contribute to the national need for well-educated scientists,

mathematicians, engineers, and technicians by supporting the retention and graduation of high-achieving, low-income students with demonstrated financial need at college of the canyons. as a two-year, hispanic serving institution (hsi) located in southern california, the college seeks to increase enrollment and graduation rates among stem majors within student populations that are underrepresented in their participation in stem fields of study, including black, latinx, female, first-generation, english language learner, and low-income groups. over its six-year duration, the project will fund scholarships to 100 unique full-time students pursuing associate degrees in biology, biological sciences, computer science, engineering, environmental science, mathematics, and physics. academically talented stem students who complete scholarship applications and demonstrate financial need will receive two-year scholarships. the project builds upon the college's successful mathematics, engineering, and science achievement (mesa) program to provide stem students with access to academic, social, and cultural capital. one of this project's distinguishing features is well-defined mentoring relationships between students and faculty aimed to increase student engagement in stem coursework and career exploration. faculty will also engage in activities designed to help them create inclusive learning environments that lead to culturally responsive and equitable stem classrooms. the project team hypothesizes that these additional supports will promote the development of positive stem-related identities among students and thereby improve retention, transfer, and success rates. this project has the potential to broaden stem participation among college of the canyons' large underrepresented and disadvantaged student population. to enhance retention, transfer, and success rates in stem among underrepresented populations, this project will explore the impact of meaningful student-faculty mentorships and culturally responsive classrooms in two-year institutions. the overall goal of this project is to increase stem degree completion of low-income, high-achieving undergraduates with demonstrated financial need. the project will create and embed a framework for enabling meaningful faculty-student mentorships within the context of a two-year institution, and empower faculty to incorporate equitable and culturally-responsive teaching elements into their stem classrooms. the project will investigate the

impact campus-wide of these interventions on the retention and success of students who remain underrepresented in stem. the knowledge gained will advance the understanding of how to successfully apply these concepts within the scope of a two-year college setting while emphasizing **\*\*diversity\*\***, equity, and inclusion. the anticipated outcomes include an increase in retention rates of stem students from underrepresented backgrounds, higher rates of graduation and transfer of stem students to four-year institutions, the inclusion of more equitable and supportive educational practices, and the upscaling of student support services by coordinating with mesa and other programs. college of the canyons will use both qualitative and quantitative measures to evaluate and monitor persistence, retention, graduation, and transfer rates for scholarship recipients and the general stem student body. the college seeks to disseminate the project?s findings to other institutions through the what works clearinghouse and other media including electronic news media, journals, news articles, stem industry publications, social media, print publications, and conference presentations. this project is funded by nsf?s scholarships in science, technology, engineering, and mathematics program, which seeks to increase the number of low-income academically talented students with demonstrated financial need who earn degrees in stem fields. it also aims to improve the education of future stem workers, and to generate knowledge about academic success, retention, transfer, graduation, and academic/career pathways of low-income students. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: HDR DSC: Data Science for Energy Transition

Awardee: University of Houston

Amount: \$1,493,016.00

Abstract: with the growing public awareness of climate change, houston, the energy capital of the world, is undertaking efforts to lead the energy transition for a more sustainable and cleaner

environment. there is urgent demand for a data science workforce equipped with broad understanding for optimizing conventional energy and leading the energy transition. this project focuses on training undergraduates and masters-level students from diverse backgrounds to achieve a wide range of knowledge and skill sets essential for the future energy industry workforce. five major public universities in greater houston are teamed up with multiple energy industry partners, ranging from large oil and gas companies to startups on energy sector data analytics. given the emphasis of participating universities on **diversity** and equity and the diverse student populations they serve, this project broadens training opportunities for groups historically underrepresented in science, technology, engineering, and mathematics (stem). statisticians, computer scientists, geophysicists, and social scientists at the university of houston (uh) main campus, uh-downtown, uh-victoria, uh-clear lake, and sam houston state university are collaborating to develop year-long educational activities under the theme of energy transition, from traditional oil-and gas-related problems to renewable energy. the curriculum contains an array of important topics including fundamental science and engineering understanding, essence of statistics and machine learning methods, and practical skill sets of programming and data visualization. social science aspects on the energy transition and its implications for society are also included in the curriculum. the program consists of: (1) five-week summer boot camps with educational modules on statistics/machine learning, cs/programming, geophysics and earth sciences, public policy, and engineering; (2) advanced courses and micro-credential training offered by participating universities in the following fall semester; (3) semester-long team research projects on problems provided by industry partners in the spring semester; and (4) summer internships and/or conference presentation opportunities to conclude the program. each year, about 40 students participate in the program, totaling about 120 student participants over 3 cohorts. a framework in which research projects can be carried out is developed. the project also promotes interaction and collaboration between academia and industry in the region, opening up more opportunities for education and research collaboration. all project data is well documented and made freely available. the student and

program-level outcomes are formally assessed, with results disseminated through publication in peer-reviewed journals and conference presentations. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: NRI: Robust and Efficient Physics-based Learning and Reasoning in Degraded Environments

Awardee: Rutgers University New Brunswick

Amount: \$1,490,276.00

Abstract: this project will perform fundamental research into developing and integrating physics-driven reasoning and planning techniques to enable autonomous robots to manipulate unknown irregular objects and navigate in unstructured, dynamic environments. the developed techniques will be deployed on robomantis: a four-legged, wheeled robot that can assist in first-response missions. the project will fill the important gap between existing research on learning models of unknown objects from data and research on developing adequate simulation tools for robotic manipulation and locomotion by answering three fundamental questions: 1) how to efficiently simulate the effects of robotic actions on objects with uncertain models? 2) how to use physics simulation tools to plan manipulation and locomotion strategies for navigating in unstructured terrains? and, 3) how to learn physical models of objects on the fly? the project builds on top of progress in computer vision, physics simulation, and planning, towards developing an efficient toolset for robotic navigation in rubble. the main technical objectives of this project are to: 1) develop physics simulation tools that can be used for efficiently inferring models of both rigid and non-rigid objects and for robust planning, 2) develop optimization tools for learning models of objects from limited vision and interaction data, 3) develop manipulation and navigation algorithms that can leverage the learned models, and 4) demonstrate the fully integrated system on a diverse range of tasks related to search and rescue operations, such as manipulating unknown objects in clutter and

navigating in rubble. the project will adopt a bayesian approach where models of objects that are typically found in piles of rubble, such as debris and rocks, will be inferred from a few rgb-d images providing partial views of the scenes, and also from their responses to forces applied by the robot during locomotion and manipulation actions. hypotheses of various models will be used to simulate the effects of the exerted forces on the objects. models that best reproduce the observed effects of the forces will be given the highest probabilities. the inferred models will then be used to plan robust manipulation and locomotion actions that allow the robot to clear its way and advance through a pile of debris. the project brings together an interdisciplinary team of investigators who have expertise in computer vision, physics simulation and planning. implementations of the developed solutions will be provided to the research community as open-source software packages. this will be coupled with the generation of educational material, especially programming assignments on manipulation challenges that require physics reasoning, which will be shared with the academic community. the material will aim to attract undergraduate students early in their studies to stem by using hands-on experience that can be provided with the use of robotics, while also exposing them to foundational methods and data-driven tools. when appropriate, efforts will be made to introduce the research, in particular the hardware demonstrations, to k-12 students to cultivate their early interests in robotics, which touches all aspects of stem. in the process, the pis will aim to leverage **\*\*diversity\*\*** programs at rutgers university to recruit and support underrepresented groups. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: CAREER: Just add water? Investigating RNA stability in desiccated soil bacteria.

Awardee: University of Arizona

Amount: \$1,466,520.00

Abstract: this award is funded in whole or in part under the american rescue plan act of 2021 (public

law 117-2). dryland soils are home to complex microbiomes that mediate processes crucial to human and planetary health, including water sustainability, soil fertility, food security, bio\*\*diversity\*\*, and variability in atmospheric co2 concentrations. drylands are particularly sensitive to the effects of drought; about 20% of global drylands are classified as "degraded" or "marginal," with an annual cost of ~\$300 billion. soil microbes persist in dry soil by entering desiccation-induced microbial dormancy. the mechanisms that allow dryland microbes to enter and exit desiccation-induced dormancy are poorly understood. this research project investigates how different groups of bacteria tackle the problem of surviving desiccation. the soil bacteria that will be investigated are abundant mediators of soil carbon cycling and agricultural health in drylands. thus, studying the mechanisms of desiccation tolerance in soil bacteria can influence decisions about how to prevent or rehabilitate degraded dryland ecosystems. the results can also lead to new methods to measure how agricultural practices focused on reducing irrigation will affect the microbes that regulate soil fertility. the project aims to attract, train, and retain undergraduates that are historically excluded in stem fields as part of a larger vision to build a diverse american stem workforce. the research aims will be conducted by students conducting authentic course-based research on drought?a topic of global and local importance. a mentorship training program will educate graduate students in effective mentorship and provide them with authentic mentorship experience. microbes in dry soils face extreme stress from increases in temperature and drought that lead to severe soil drying. although non-spore forming soil bacteria in drylands can persist without water for months at a time through desiccation-induced dormancy, the molecular systems that control the tolerance and resiliency to prolonged desiccation are largely unknown. specifically, the effects of drying on rna?the labile molecular bridge between genetic information and functional protein?are virtually unexplored. the hypothesis that water availability regulates rna stability, which in turn controls desiccation tolerance will be tested. to test this hypothesis, the primary investigator and a team of research students will quantify the relationship between desiccation tolerance and rna stability in cultures of diverse soil bacteria by 1) measuring the desiccation tolerance of non-spore forming soil bacteria; 2)

relating desiccation tolerance to mrna activity after drying; and 3) calculating the gene-resolved rna half-lives in desiccated and rehydrated soil bacteria. determining the molecular controls of bacterial desiccation tolerance is vital to understand dryland vulnerability ahead of visible aboveground changes and will inform development of soil inoculants better suited to drought-impacted agricultural systems. the primary investigator and student research teams will explain how the stability of different rnas influence desiccation tolerance in diverse soil bacteria with course-based research activities. the primary investigator will apply an innovative graduate student mentorship training program that connects historically excluded graduate and undergraduate students. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Culturally Responsive, Affective-Focused Teaching of Science and Mathematics

Awardee: University of Florida

Amount: \$1,448,590.00

Abstract: students and professionals who identify as black, indigenous, or people of color (bipoc) continue to be underrepresented in stem fields. broadening participation in stem requires a change in how k-12 stem teachers engage and educate students who identify as bipoc. research has demonstrated that cultural and social justice connections can lead to positive academic outcomes for students who identify as bipoc in science and mathematics. this project will provide a field-based science and mathematics teacher education program that supports teaching focused on students' affective development through culturally responsive practices. in this project, affective development is defined by students' abilities to incorporate their science and mathematics learning into their own unique personal value systems. the project's field-based teacher education program takes place over a two-year period and models how culturally responsive and affective instruction can occur in the stem classroom to engage students. the project participants include 48 secondary science and

mathematics teachers who work with about 5300 students in a district with some of the most persistent and pronounced educational equity issues in the state of florida. the associated research will have implications for theory and practice that can be extended to improve stem educator development in schools and districts throughout the country. this aligns with nsf's commitment to advancing k-12 student and teacher learning in the stem disciplines through research-based design and development of innovative models. using design-based implementation research, this project will accomplish the following objectives: (1) transform the practices of a district-wide set of 48 secondary science and mathematics teachers by equipping them with culturally responsive, affective-focused practices and leadership skills; (2) construct tools and resources that will serve as open-access professional development materials shared widely via learning management tools; and (3) develop an evidence-based and adaptable theory of change to share widely with the stem education community. the research plan draws on both qualitative and quantitative research methods to study the experiences and changes of science and mathematics teachers and their students as they experience continuously refined versions of the teacher education model. in particular, this project focuses on studying teacher and student outcomes, including teachers' culturally responsive, affective-focused practices and self-efficacy, their understanding of student values and cultural backgrounds, and their attitudes toward cultural \*\*diversity\*\*; growth in students' affective development and stem achievement, their interest in stem careers, and stem identity development. answers to the research questions will provide empirically-driven means for developing both the practical tools and the theoretical models of change toward stem teacher transformation and positive impacts for students who identify as bipoc. the discovery research prek-12 program (drk-12) seeks to significantly enhance the learning and teaching of science, technology, engineering and mathematics (stem) by prek-12 students and teachers, through research and development of innovative resources, models and tools. projects in the drk-12 program build on fundamental research in stem education and prior research and development efforts that provide theoretical and empirical justification for proposed projects. this award reflects nsf's

statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: SCC-IRG Track 2: The "Community Tech Workers": A Community-Driven Model to Support Economic Mobility and Bridge the Digital Divide in the U.S.

Awardee: Regents of the University of Michigan - Ann Arbor

Amount: \$1,435,769.00

Abstract: information and communication technologies allow individuals to apply for benefits like health care and housing, to have groceries delivered to their homes, to schedule/attend healthcare appointments, and to apply for employment. however, digital inequalities in terms of access, use, and self-efficacy reflect offline socioeconomic inequalities and pose a serious threat to today's increasingly tech-reliant society. the digital divide is a multidimensional phenomenon that refers to three levels of differences: first, in who has access to the internet; second, who has skills to use the internet; and third, how the internet is actually used. many efforts to bridge the digital divide have failed because they only address the first level (e.g., providing public wifi, computers, computer labs) without continued onboarding and training support. this project aims to address digital disparities in southeast michigan by leveraging and building the digital literacy of local experts (level 2) to provide digital support to communities (levels 2 and 3). inspired by the transformative community health worker model, this work proposes "community tech workers" (ctw), a community-driven, "train the trainer" approach that promotes digital literacy in communities. participants include a public housing authority in detroit's eastside neighborhood, a refugee resettlement agency that serves refugees in a public housing community in ypsilanti, an advisory board consisting of local workforce development agencies and industry representation, and a steering committee of individuals who are involved in outreach, education, and interventions related to increasing digital proficiency and public health. the research will (1) develop and validate a survey instrument measure to assess community digital

capacity; (2) develop an initial ctw training program; (3) assess the training, learning experience, and impact of the ctws within each community; and (4) capture and evaluate the economic value of the ctw model. the survey instrument will extend existing assessments for measuring individual digital capacity to create a novel instrument that measures digital capacities at a community grain size. this instrument will be validated across two communities, and then be used to measure the impact of the ctw activities on the two communities over time. ctw training activities will be evaluated via interviews with participants and observations of the training sessions. recommendations for a credentialing system to document ctw proficiency and for a marketplace system to promote employment opportunities will be elicited via participatory co-design sessions, information which can be used to inform integration with or development of job recommendation and gig work applications. finally, data on costs will be collected to generate a cost-benefit analysis of the ctw model, to explore its further scalability. secondary outcomes of the work include providing local residents with free training to obtain the necessary skills to become a ctw, and in the future, temporary employment for selected tech workers and connections to local it employment opportunities. incorporating the model across multiple communities will help uncover generalizable requirements for creating equitable socio-technical infrastructures that support community digital capacity and expand local opportunities. this systemic perspective on the development and deployment of the ctw model aligns well with the goal of the nsf smart and connected communities (s&cc) program, which is to accelerate the creation of the scientific and engineering foundations that will enable smart and connected communities to bring about new levels of economic opportunity and growth, safety and security, health and wellness, accessibility and inclusivity, and overall quality of life. this project is also supported by the improving undergraduate stem education program, which seeks to support projects that have high potential for broader societal impacts, including improved **\*\*diversity\*\*** of students and instructors participating in stem education, professional development for instructors to ensure adoption of new and effective pedagogical techniques that meet the changing needs of students, and projects that promote institutional partnerships for collaborative research and

development. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Building a Youth-Led Learning Community through Automating Hydroponic Systems

Awardee: Boston College

Amount: \$1,414,733.00

Abstract: in this project, youth will apply scientific and computational science concepts and practices by learning to create and build automated systems where they can grow their own food. these specialized growing systems will utilize hydroponics where plants are grown without soil. computational science is an interdisciplinary area that combines skills and knowledge from science, computation, computer science, engineering, and mathematics to solve problems. the prevalence of computational science in industry and everyday lives necessitates the development of a stem workforce knowledgeable to solve complex real-world problems. researchers will train high school youth to program low-cost micro-controllers to collect data and use that data to automate hydroponic systems. to support the high school youth's interest in obtaining a post-secondary degree, they will be mentored by first-generation college students from alumni of boston college's college bound program and lasell university's pathways to **\*\*diversity\*\***. this project will study ways to design an internal learning environment that promotes youth skills and interest in pursuing stem careers. utilizing a design-based research framework and drawing upon a mixed-method data collection approach including observations, surveys, interviews, and youth generated artifacts, the project team will explore how and in what ways the use of physical computing coupled with computational science improves youth interest and knowledge to pursue stem careers. survey data will be analyzed by first evaluating the measurement quality of the latent variables using confirmatory factor analysis and then using latent variable growth modeling to assess changes in repeated measures for four time points. the research and evaluation work will track 500 youth and their families over

time and evaluate what aspects of the program are critical to youth success and stem career self-efficacy and awareness. this work offers an approach to support youth in examining careers across fields of agriculture, computation, and science teaching. this project is funded by the innovative technology experiences for students and teachers (itest) program, which supports projects that build understandings of practices, program elements, contexts and processes contributing to increasing students' knowledge and interest in science, technology, engineering, and mathematics (stem) and information and communication technology (ict) careers. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Increasing STEM Persistence by Supporting Apprentice Research Experiences (AREs) as a Model for Institutional Change in Community Colleges

Awardee: Wake Technical Community College

Amount: \$1,399,976.00

Abstract: this project aims to serve the national interest by iteratively assessing and improving the stem academic research and training (start) program, an apprenticeship research experience (are) at wake technical community college. the project will contribute to understanding the effects of are - especially uncommon and understudied at 2-year colleges - on community college students?

persistence in college and in stem careers. this project will develop a sustainable model for co-curricular apprenticeship-style mentored undergraduate research programs and help build the case for state and donor funding for undergraduate research experiences and internships at community colleges across north carolina. the project will enhance a current program, recruit students from populations underrepresented in stem, and further develop relationships with numerous research partners. by supporting students with paid internships, the project will increase access to stem careers for low-income students. training modules for mentors and students will also be developed. the project offers a distinct opportunity to recruit underrepresented minorities and first-generation college students into stem research and prepare them for successful academic and professional careers.

the project goal is to develop a sustainable and scalable undergraduate research and internship program model for 2- and 4-year colleges to partner in undergraduate research. such partnerships are expected to foster student success in transfer and persistence in bachelor's degree programs in stem. funds will support approximately 50 student interns each semester resulting in 400 paid internships over the course of the project. this project will develop a community of inquiry (coi) framework-based model for strengthening undergraduate research experiences in the community college context. the project will utilize a randomized controlled trial that meets the "what works clearinghouse" standards, and includes research questions on the impact of participation in start undergraduate research on student outcomes, e.g. retention and persistence in college and in stem fields, academic confidence, student identity and awareness, and scientific literacy and research skills. furthermore, the research questions examine the impact of start on the college, e.g. the impact on the **diversity** of student participation in stem fields, the skills and comfort of mentors in engaging in mentoring activities, and the institution's support for mentors and research. the external evaluator and project faculty will prepare manuscripts of findings for publication and disseminate them via national conferences, reaching audiences of both practitioners and researchers. academic partners include north carolina agricultural and technical state university, the university of north carolina at chapel hill, and north carolina state university. by

creating undergraduate research and internship opportunities for community college students the project is a model to build the stem pipeline. funding for this project comes from the advanced technological education program through the program description on advancing innovation and impact in undergraduate stem education at two-year institutions of higher education (pd 21-7980) which promotes innovative and evidence-based practices in undergraduate stem education in the community college sector. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: EDGE CMT: Origin and diversification of butterfly color patterns

Awardee: Cornell University

Amount: \$1,390,000.00

Abstract: when we look across the **\*\*diversity\*\*** of life, we see many complex traits that are unique to certain groups of organisms. feathers in birds, hair in mammals, and flowers in angiosperms, for example. it is a major question in biology how these kinds of novel traits first appear. what is the genetic basis of newness? recent work across many species has shown that novel traits such as these are largely generated by old genes that have been repurposed for new roles. novelty appears to emerge through a reshuffling of older genetic building blocks, which are proposed to be ancient subnetworks of interacting genes. but where do these gene networks come from in the first place? and how are they rewired to generate complex new traits? with this funding, reed and colleagues are beginning to address these questions by looking at the origin of color in butterflies. they are characterizing the gene networks that underlie color pigmentation in butterflies, and they are determining how specific genetic changes caused these networks to be repurposed from ancestral roles in processes such as neural development, to make butterfly wing patterns. this work serves as a case study to help biologists understand the developmental genetic mechanisms that underlie the

genesis and diversification of complex biological traits. the project also includes training in biology research skills of graduate and undergraduate students from diverse backgrounds, the development and dissemination of instructional videos for genomic methods, and the establishment of a web-based resource for functional genomics in butterflies. a core concept in modern biology is that novel morphological traits originate from gene regulatory networks that predate the traits themselves. surprisingly, however, little is known about the specific genetic mechanisms that underlie the origin and repurposing of such gene networks. with this funding, reed and colleagues develop the regulatory network encompassing the butterfly color pattern gene *optix* into a model for exploring the regulatory architecture of trait diversification. *optix* is a homeobox transcription factor that plays a deeply ancestral role in neural and retinal development in both invertebrates and vertebrates. in butterflies, however, this gene underwent a radical co-option event where it gained a novel function as a master regulator of wing pigmentation, including playing key roles in adaptation and mimicry. thus, the researchers have a situation in lepidoptera where they can pinpoint the phylogenetic timing of a major *optix* co-option and repurposing event, where this gene appeared as a *de novo* regulator of color patterns. reed and colleagues are leveraging this opportunity to take a multi-species comparative approach to characterize the history of the *optix* regulatory network as it gained its novel adaptive function in color pattern regulation. using *optix* as the focal point, they are characterizing the cis-, upstream, and downstream regulatory dynamics of regulatory co-option, and construct a comprehensive case study of how a new gene regulatory network can emerge from the genome to generate new morphological features ? in this case, color itself. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Applying Student Knowledge for Success in Cybersecurity and Data Science

Awardee: New Jersey Institute of Technology

Amount: \$1,384,756.00

Abstract: this project will contribute to the national need for well-educated scientists, mathematicians, engineers, and technicians by supporting the retention and graduation of high-achieving, low-income students with demonstrated financial need at kean university, the new jersey institute of technology, fairleigh dickinson university, brookdale community college, and union county college. in particular, it responds to areas of national need in cybersecurity and data science by increasing the number of students graduating in computer science (cs) and information technology (it). moreover, the project will build regional workforce strength and contribute to the knowledge base on the role of student competence and belonging in ensuring persistence to degree attainment. over its five-year duration, a total of 256 students will benefit, receiving scholarships to complete cs or it degrees. project components include scholarship support for students, undergraduate research and/or professional experience opportunities prior to graduation, and

generation of new knowledge through research on economic realities for students and impact on career trajectories in cybersecurity and data science. students in this program will be prepared to enter the scientific workforce or graduate school as competent, highly trained individuals with a background in teamwork and research. furthermore, they will contribute to increased professional **\*\*diversity\*\*** in the fields of cs and it, and serve as role models to members of their communities.

the students recruited for this program will participate in workshops, take advantage of cohort experiences, and interact closely with faculty who will provide i) academic advising, ii) guidance for navigating higher education and postgraduate opportunities, and iii) supervision of teamwork, research, and working professional experiences. through undergraduate research opportunities and experiences from participation in faculty research programs and/or existing summer research and internship programs, these individual and cohort experiences will provide a basis for overall intellectual growth and promote increased student confidence, retention, and timely degree completion. these academic outcomes are in turn expected to allow students to successfully navigate common attrition points including financial hardship and professional identity development for post-graduate employment and continued education. the project's academic environment includes student-faculty advising and undergraduate research activities, using the affinity research group (arg) model and peer-mentoring. the use of teamwork, collaboration and student-motivated question and answer sessions will positively support research in the field of computer science and information technology regarding educational impact and retention, particularly for minorities, female, and first-generation students. this project is funded by nsf's scholarships in science, technology, engineering, and mathematics program, which seeks to increase the number of low-income academically talented students with demonstrated financial need who earn degrees in stem fields. it also aims to improve the education of future stem workers, and to generate knowledge about academic success, retention, transfer, graduation, and academic/career pathways of low-income students. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review

criteria.

Title: Collaborative Research: WINTRE-MIX: Winter Precipitation Type Research Multi-scale Experiment

Awardee: SUNY at Albany

Amount: \$1,369,548.00

Abstract: during near-freezing weather conditions, a **\*\*diversity\*\*** of surface precipitation types are possible, including: rain, drizzle, freezing rain, freezing drizzle, wet snow, ice pellets, and snow. such near freezing precipitation affects wide swaths of the united states and canada, impacting aviation, road transportation, power generation and distribution, winter recreation, ecology, and hydrology.

this award is for a field experiment, named the winter precipitation type research multi-scale experiment (wintre-mix) with the overarching goal of improving understanding of how a variety of processes influence the variability and predictability of the type and amount of precipitation that falls during winter weather events. the project has direct societal impact through the potential for improved forecasting of these events. additionally, the project will have significant student involvement, public outreach events, and citizen science participation. the wintre-mix campaign will be conducted in southern quebec, canada and northern ny and vt in the united states. the canadian national research council convair-580 research aircraft and the university of illinois mobile radars will be deployed along with a host of surface-based instrumentation in february and march of 2022 to make observations that can be used to determine the thermodynamic, dynamic, and microphysical processes that interact to determine near-freezing precipitation type. more specifically, the project has three overarching scientific questions that will be addressed using observations, analysis, and modeling: 1) how do mesoscale dynamics modulate near-freezing precipitation, 2) how do microscale processes modulate near-freezing precipitation, and 3) how do multi-scale processes combine to determine the predictability of near-freezing precipitation? this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Awardee: Temple University

Amount: \$1,323,467.00

Abstract: this project will contribute to the national need for well-educated scientists, mathematicians, engineers, and technicians by supporting the retention and graduation of

high-achieving, low-income students in the college of science and technology (cst) at temple university. in particular the project intends to provide 96 scholarships to support 32 unique scholarship recipients to support the completion of stem degrees in chemistry, biology, physics, mathematics, and earth and environmental sciences coupled with a minor in information science. the driving force behind the project team's efforts is to democratize access to economic opportunities in the technology-focused stem workforce for high-achieving, low-income students. lack of knowledge and skills in information sciences can be a barrier to workforce competitiveness and to economic mobility for low-income students. to overcome this barrier, the project leaders have identified intentional, multidisciplinary academic pathways that provide high-achieving, low-income students with the ability to focus on their chosen primary stem major, such as biology or earth science, in combination with specialized study in information science. such integrated academic pathways align with emerging needs for scientists to have more knowledge and skills in information science to collect, represent, analyze, and discover meaningful models by applying computational solutions to large data sets. the project hypothesizes that providing financial support to explore pathways for integrated study of stem and information science, supported through cohort-based curricular and co-curricular activities, can ultimately lead to higher stem degree attainment and workforce entry among low-income students. through this project, researchers will develop and implement a model program that supports students from low-income backgrounds to complete academic degree programs with clearly identified academic pathways that promote degree attainment for undergraduate stem majors and add value through integrated study of information science. the approach builds on evidence-based practices that have been shown to positively impact individual student outcomes; program elements are designed to emphasize connections across disciplines, integrate socially relevant applications of content knowledge, connect to professional practices, and develop identity and community through service-learning projects. additionally, the program is also designed to broaden participation of underrepresented groups in computing, with program elements that implement evidence-based approaches for **\*\*diversity\*\***,

equity, and inclusion in stem education. the project will advance knowledge about the perceptions of stem majors in choosing to pursue integrated academic pathways, as well as the impact on academic and workforce preparation for stem students who complete such pathways. this project is funded by nsf's scholarships in science, technology, engineering, and mathematics program, which seeks to increase the number of low-income academically talented students with demonstrated financial need who earn degrees in stem fields. it also aims to improve the education of future stem workers, and to generate knowledge about academic success, retention, transfer, graduation, and academic/career pathways of low-income students. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: ADVANCE Partnership: Building Community Understanding of the Institutional Compensation System

Awardee: Rochester Institute of Tech

Amount: \$1,314,681.00

Abstract: this project aims to significantly expand knowledge of best practices for faculty compensation to a broader community in higher education and provide critical insights to guide compensation practices. salary outcomes and pay practices are closely related to the quality of work life and inform our knowledge of what (and who) is important to the organization. in this domain, institutional structures and systems of power are influential. women consistently earn less than men, even when controlling for demographic and background variables; a wage gap that increases for women of color. in higher education, this gap persists among faculty, particularly at institutions with the highest levels of research. this project's objective is to improve institutional understanding and influence actions regarding pay equity through broader comprehension of compensation structures. project activities have three aims: first, engage administrative units (human resources, institutional research, **\*\*diversity\*\***/inclusion, legal, and academic affairs) in a collaborative relationship supported by university leadership. second, enhance pay decision-makers' understanding of and basis for pay decisions, and their ability to communicate to individuals how their pay is determined. third, increase faculty knowledge of institutional pay practices while emphasizing the importance of inclusion and institutional values. expected outcomes from this work include improvements in institutional policies and practices, faculty perceptions of pay equity, leadership skills of pay decision-makers, and institutional engagement beyond the project partners. the project involves collaborations with three university partners villanova, drexel, and gallaudet, the american

association of university women (aaup), and the nsf includes hub and the aspire alliance. the three partner-universities will undertake actions to: promote an inclusive work environment and informed faculty community that understands its financial model about compensation; align university resources with institutional values to promote enhanced equity; and support systemic, sustainable change through institutionalization of compensation interventions. the project will employ a multi-frame organizational analysis approach, integrating structural, human resource, political, and symbolic aspects of organizational theory, to better understand each partner-university. the partner cohort will explore multiple dimensions of justice regarding salary ? distributive, procedural, interpersonal, and informational ? through workshops, coaching sessions, and organizational action plans. ongoing formative assessment will include input from women of color and deaf and hard-of-hearing women. the project's reach will expand to additional institutions through the partnerships with the american association of university women, nsf includes hub, and the aspire alliance. expected outcomes include implementation of compensation-related accountability measures, improved faculty understanding of pay practices, increased comprehension of equity among salary decision-makers, and infrastructure changes to support ongoing progress. the nsf advance program is designed to foster gender equity through a focus on the identification and elimination of organizational barriers that impede the full participation and advancement of diverse faculty in academic institutions.? organizational barriers that inhibit equity may exist in policies, processes, practices, and the organizational culture and climate.? advance "partnership" awards provide support for projects that scale-up evidence based systemic change strategies to enhance gender equity for stem faculty regionally or nationally. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Global Sustainability Scholars for Sustainable Oceans: building a network of transdisciplinary scientists and practitioners that represent humanity?s future.

Awardee: University of Colorado at Boulder

Amount: \$1,312,490.00

Abstract: humanity faces profound challenges in the 21st century. from a rapidly rising population, a warming climate, increased demand for food, fiber, and water, and a rapid loss of bio\*\*diversity\*\*

and ecosystem services, we face environmental problems that are more pervasive and serious than at any time in our history. the global ocean plays a critical role in the earth system affecting atmospheric, geochemical, ecological, and social systems in a multitude of interconnected ways. to predict changes, understand their impacts on natural and social systems, and develop approaches that allow us to adapt to and mitigate the impacts, requires more integrative approaches to the study of ocean systems, and this, in turn, will require large-scale cooperation across disciplinary, cultural, and national boundaries. accordingly, the next generation of sustainability leaders will require a broad set of skills to engage in inter- and trans-disciplinary teams to solve the complex environmental issues that face humanity. this project seeks to develop the next generation of international trans-disciplinary sustainability science leaders through a collaborative fellowship program that connects undergraduates, graduate students and post-doctoral researchers with today's trans-disciplinary sustainability science leaders. using a cohort model, the participants work with international, transdisciplinary research teams on ocean sustainability projects funded by the belmont forum, over the course of several field seasons. through these research opportunities and training experiences, the program seeks to provide the participants with trans-cultural, trans-disciplinary, and trans-national cooperative opportunities which will be essential in generating and applying knowledge to actions that speed the transition toward a more globally sustainable future. the program seeks to help the participants be nimble and fluent across research disciplines, and to develop collaborative leadership, communication, and negotiation skills. the project will provide opportunities for students and researchers from underrepresented groups to engage in transdisciplinary, team-oriented, international science with direct relevance to some of the most challenging issues in ocean sustainability. engaging over several consecutive field seasons, will further build community that is likely to last well beyond the lifetime of the project and help generate the diverse workforce of the future. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Sustaining The Utqiagvik Aerosol Record of Decades (STUARD)

Awardee: University of California-San Diego Scripps Inst of Oceanography

Amount: \$1,299,527.00

Abstract: the arctic is warming faster than any other place on earth, with sea ice declining rapidly and sources of sea spray and aerosol emissions derived from living organisms (biogenic) are consequently changing. utqiagvik is at the forefront of this change, abutting one of the largest areas of sea ice loss. these atmospheric aerosols could have far-reaching impacts to both the climate, environment and resident community. because this change has happened largely in the last decade, now is an important time to document changes and continue a data record that will allow for a characterization of the new arctic. the longest and most complete record of airborne fine particles (or ?aerosol?) and their properties in the american arctic is that of utqiagvik, where nsf, the national oceanic and atmospheric administration and the department of energy have contributed to making this unique location serve as a regional record of changes in atmospheric aerosol properties. that record has served as the basis for hundreds of publications on questions from atmospheric chemistry to climate science to ecology and bio\*\*diversity\*\* conservation, which clearly demonstrate the broad, cross-disciplinary scientific value of these measurements. this research will extend the baseline measurements of this arctic aerosol record, including a continuation of the 15-year record of submicron inorganic components, re-instituting the 2-year record of organic components collected a decade ago, enhancing the chemical analysis with sulfur isotopes to improve interpretation of emission sources, continuing particle number size distribution measurements, and re-starting cloud condensation nuclei measurements. re-starting sampling for organic components provides a comparison to that of 2008-2010, documenting the myriad of source changes in the last decade. observations for continuing size distribution records and re-starting cloud condensation nuclei measurements provides the link from the chemical record of sources to the physical impacts on

climate and the environment. this project will also allow analysis and archiving of the last 7 years of inorganic filters that were collected and the next 5 years, extending the inorganic aerosol composition record to almost 30 years. in addition to making the data widely available for a breadth of research, a journalist will publish articles in local news media to broaden the awareness of utqiagvik's historic role as an arctic observatory. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Digitization TCN: Extending Anthophila research through image and trait digitization (Big-Bee)

Awardee: University of California-Santa Barbara

Amount: \$1,288,241.00

Abstract: declining populations of bees impact plant-pollinator interactions in both natural and agricultural systems. while bees and other insects pollinate most wild plants, and are critical to sustain a large proportion of global food production, they are decreasing in both numbers and **\*\*diversity\*\***. our understanding of the factors driving these declines is limited because we lack sufficient data on the distribution of bee species, and on the behavioral and anatomical traits that may make them either vulnerable or resilient to human-induced environmental changes, such as habitat loss and climate change. fortunately, wild bees have been collected by researchers and deposited in natural history collections for over 100 years, retaining a wealth of associated attributes that can be extracted from specimen images. this project will digitally capture data and images from

these historic specimens, develop tools to measure bee traits from these images, and generate a comprehensive bee trait and image dataset to measure changes through time. this will increase our understanding of specific traits that put bee species at risk of decline - a critical need for both sustaining our agricultural economy and the conservation of our natural resources. in addition, the large image datasets created by this project can be used for new artificial intelligence identification tools that will help improve our future pollinator observation and monitoring efforts. the big-bee thematic collection network (big-bee tcn) will create over one million high-resolution 2d and 3d images of bee specimens, representing over 5,000 worldwide bee species, including all of the major pollinating species of the united states. the big-bee network includes 13 institutions and partnerships with us government agencies. novel mechanisms for sharing image datasets will be developed and datasets of bee traits will be available through an open data portal, the bee library, for research and education. the big-bee project will engage the general public in research through community science via crowdsourcing trait measurements and data transcription from images. in addition, training and professional development for natural history collection staff, researchers, and university students in data science will be provided through the creation and implementation of workshops focusing on bee traits and species identification. all data resulting from this award will be shared with and publicly available through the national digitized biocollections resource, idigbio.org. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Frameworks: Convergence of Bayesian inverse methods and scientific machine learning in Earth system models through universal differentiable programming

Awardee: University of Texas at Austin

Amount: \$1,278,970.00

Abstract: understanding and quantifying parameter sensitivity of simulated systems, such as the

numerical models of physical systems and mathematical renderings of neural networks, are essential in simulation-based science (sbs) and scientific machine learning (sciml). they are the key ingredients in bayesian inference and neural network training. seizing on the opportunity of emerging open-source earth system model development in the julia high-level programming language, this project is endowing these open-source models with automatic differentiation (ad) enabled derivative information, making these converging data science and simulation-based science tools available to a much broader research and data science community. enabling a general-purpose ad framework which can handle both large-scale earth system models as well as sciml algorithms, such as physics-informed neural networks or neural differential equations, will enable seamless integration of these approaches for hybrid bayesian inversion and bayesian machine learning. it merges big data science, in which available data enable model discovery with sparse data science, and the model structure is exploited in the selection of surrogate models representing data-informed subspaces and fulfilling conservation laws. the emerging julia language engages a new generation of researchers and software engineers, channeling much needed talent into computational science approaches to climate modeling. through dedicated community outreach programs (e.g., hackathons, minisymposia, tutorials) the project team will be working toward increasing equity, **diversity**, and inclusion across the participating disciplines. the project is developing a framework for universal differentiable programming and open-source, general-purpose ad that unifies these algorithmic frameworks within julia programming language. the general-purpose ad framework in julia leverages the composability of julia software packages and the differentiable programming approach that underlies many of the sciml and high-performance scientific computing packages. compared to most current modeling systems targeted for hpc, julia is ideally suited for heterogeneous parallel computing hardware (e.g., cuda, rocm, oneapi, arm, powerpc, x86 64, tpus). the project is bringing together expertise in ad targeted at earth system data assimilation in high performance computing environments with sciml expertise. the project team is working with the julia computing organization and package developers to ensure sustainability of the

developed frameworks. the project's earth system flagship applications consist of (i) an open-source, ad-enabled ocean general circulation model that is being developed separately as part of the climate modelling alliance (clima), and (2) an open-source, ad-enabled ice flow model. each of these application frameworks is being made available to the community for science application, in which derivative (gradient or hessian) information represent key algorithmic enabling tools. these include sciml-based training of surrogate models (data-driven and/or model-informed), parameter and state estimation, data assimilation for model initialization, uncertainty quantification (hessian-based and gradient-informed mcmc) and quantitative observing system design. academic and industry partners are involved, who are using the frameworks for developing efficient power grids, personalized precision pharmacometrics, and improved eeg design. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: RoL: The Evolution of the Genotype-Phenotype Map across Budding Yeasts

Awardee: University of Wisconsin-Madison

Amount: \$1,250,014.00

Abstract: how organisms' external characteristics or traits are encoded in their genomes and how they change over time represent important and largely unanswered biological questions. this project will address these questions by studying the metabolisms and genomes of the more than 1,000 known species of budding yeasts and their evolution. some of these yeast species are important opportunistic pathogens, while others are of great industrial relevance as producers of foods, beverages, medicines, and biofuels. this project will span multiple scales of biological organization (from molecules to cells, species, and beyond) and ~400 million years of evolution to yield fundamental insights into how traits are encoded in genomes, how new functions evolve, and how

the relationship between traits and genomes itself evolves. the project will support the wild yeast and computational genomics programs, two established and highly successful educational and training programs that immerse early-stage undergraduate students, including those from underrepresented backgrounds, in authentic, discovery-driven research. using draft genomes for nearly all known budding yeast species and state-of-the-art genome-editing tools that are broadly active in diverse species, this project will predict the connection of every metabolic gene in every yeast species? genome to its function(s), as well as examine the evolution of every known metabolic gene, pathway, and trait across the budding yeast subphylum saccharomycotina. through genome-scale evolutionary analyses and targeted functional experiments on key representative taxa spanning budding yeast genomic and metabolic **\*\*diversity\*\***, this project will functionally characterize how between-taxa variation at the level of genotypes gives rise to variation at the level of phenotypes. in particular, the project will chart how variation at the level of dna, rna, proteins, and metabolites sequentially transforms genetic variation into biochemical functions and physiological traits with an emphasis on functionally characterizing gaps and correcting discrepancies in the predicted genotype-phenotype map. this project is jointly funded by the evolutionary processes program in the division of environmental biology and the genetic mechanisms program in the division of molecular and cellular biosciences of the directorate for biological sciences. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Dimensions US-China: Collaborative Research: Quantifying the Impact of Eutrophication on the World's Grassland Soil Microbial Biodiversity and Functioning

Awardee: University of Oklahoma Norman Campus

Amount: \$1,250,000.00

Abstract: human activities are increasing the amount of biologically limiting nutrients, such nitrogen

(n) and phosphorus (p), flowing into ecosystems on every continent, and this increased nutrient supply is causing dramatic impacts such as bio\*\*diversity\*\* loss. microbes comprise most of the bio\*\*diversity\*\* on earth, and the \*\*diversity\*\* of microbes in the soil is a critical link in maintaining the health of our ecosystems. however, we have little understanding of how alteration of global nutrient supplies are affecting soil microbial \*\*diversity\*\*. the proposed work will quantify how increased nutrient supplies affect soil microbial \*\*diversity\*\* and how these changes affect the functioning of grassland ecosystems around the world. the research will leverage a worldwide network of scientists, the nutrient network (nutnet), who are replicating an identical nutrient-addition experiment at more than 100 grassland sites across 26 countries. using this global research platform, this project will explore different ?diversities? of the soil microbes by counting their identities (taxonomic \*\*diversity\*\*, td), their evolutionary relationships (phylogenetic \*\*diversity\*\*, pd), the genes encoded in their dna (genetic \*\*diversity\*\*, gd), and what they are doing (functional \*\*diversity\*\*, fd). the scientists on this research team will not only determine how these different dimensions of \*\*diversity\*\* respond to the nutrient change but also why they are changing. are microbial communities changing because some microbes can grow better (abiotic filtering), compete or cooperate with other microbes or plants (biotic interactions), or are good or bad at migration (dispersal), or appear by chance (drift)? this project will develop new mathematical models to predict how nutrients change the \*\*diversity\*\* of soil microbes and their functions in different regions in the future. broader impacts of this project include (i) increased public engagement and literacy in stem via k12 education that will reach over 4,000 k-12 students including from under-served schools using nutnet plots set up for education at cedar creek and activities at oklahoma; (ii) enhanced research infrastructure of the global nutnet collaboration, which benefits the greater research community via published data, provision of samples, and space for additional projects; and (iii) advanced training in international cross-disciplinary collaboration for project post-docs and students, that will generate a more competitive workforce to engage in systems-level problem solving for agriculture, environment, ecology and climate research. the project will use high throughput

metagenomics technologies and integrative mathematical and statistical modeling to analyze soil grassland microbial **diversity** responses to experimental eutrophication along global gradients in climate, plant **diversity**, and edaphic conditions. the research will test theory-based predictions about the responses of soil microbes to nutrient supply across scales of space and time, generating novel insights into: (i) global patterns of soil microbial **diversity** (td, pd, gd, fd) along broad gradients of climate, plant **diversity**, and edaphic conditions; (ii) the context-dependence and interactive effects of n and p supply on grassland soil microbial communities, nutrients, and soil c storage; (iii) the importance of plant, microbe and soil elemental stoichiometry for controlling the responses of microbial **diversity** and functioning to nutrient supply, as well as the role of plant-microbe interactions in mediating plant responses to nutrient addition; (iv) the relative importance of stochastic (e.g., dispersal) and deterministic (e.g., abiotic filtering, biotic interactions) processes controlling responses by each of the dimensions of microbial **diversity** to nutrient addition across global environmental and geographic gradients; (v) the importance of **diversity** and community assembly in controlling soil microbial ecosystem functioning, and the influence of environmental factors (e.g., soil, plant, climate, geography); (vi) potential ?biomarkers? (key taxa or genes) of grassland soil functions; (vii) novel metagenomics-enabled ecosystem models for global simulation of grassland soil c dynamics; and (viii) model-inferred impacts of nutrient addition on soil c dynamics across biogeographic gradients in climate, plants and edaphic conditions. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: LIGO Instrument and Data Characterization

Awardee: Louisiana State University

Amount: \$1,210,000.00

Abstract: this award supports research in relativity and relativistic astrophysics and it addresses the

priority areas of nsf's "windows on the universe" big idea. the last several years were very exciting in gravitational wave astronomy, with the first detection of gravitational waves in 2015 from a collision of black holes 1.3 billion years ago, and with more than 50 detections published in 2021; the lsu group has been a critical contributor to these discoveries. the group's activities in the next years will focus on aspects of improvement of the advanced ligo detectors and the characterization of data from the advanced ligo interferometer. these efforts are fully integrated with those of the ligo scientific collaboration (lsc) and are closely related with the activities of the ligo livingston observatory, since that observatory is located only 30 miles from the lsu campus. in doing its research, the group will train students and a postdoc who will add to the quality and **\*\*diversity\*\*** of the stem workforce, as well as share the research with the general public. the lsu group will pursue research activities in two main topics, all coordinated with the lsc and key to the improvement of detection rates of gravitational waves with the advanced ligo detectors. the first topic is about characterizing the advanced ligo detector and applications to future designs; the group will help diagnosing and improving the detector's noise in the frequency domain due to the sensing and control of the alignment degrees of freedom, and the feedback control of the suspended masses. the group will model the performance of the system, compare models with actual performance, and then apply the models and the experience to the conceptual development of such systems for upgraded detectors. the second topic is analyzing data from advanced ligo detector; the group will identify instrumental artifacts, in particular those related to the group's expertise on scattering sources. the group will eliminate the cause of the transients when possible, and find out the artifacts that most affect the low latency searches for astrophysical signals in ligo data. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: PlantSynBio: Identification and Design of Transcriptional Activation

## Domains Across Plant Species

Awardee: Duke University

Amount: \$1,204,813.00

Abstract: every plant begins life as a seed with one cell and one genome. in order for a plant to grow, the cells must divide and turn into different kinds of cells by turning on different genes. leaf cells turn on leaf genes; root cells turn on root genes. this process of turning genes on and off requires specialized proteins called transcription factors. transcription factors also allow plants to turn genes on or off to respond to stresses like drought or pests and pathogens. transcription factors turn genes on using specialized regions called "activation domains." the first part of this project will use technologies we developed to identify activation domains on all the transcription factors of one widely studied plant species, arabidopsis. the data we collect will power our computational models for predicting activation domains in other plants. the final portion of this project will build synthetic transcription factors that can be used to engineer gene regulation in other plants. this research will create useful and powerful tools for plant biologists and plant breeders. this collaboration between three research teams creates a unique interdisciplinary training environment for undergraduates, graduate students, and postdoctoral research fellows. our team is committed to building a supportive environment that fosters equity, **\*\*diversity\*\*** and inclusion. the three pi's come from backgrounds that have been traditionally excluded from science. two of the pi's are building on the success of their nsf career awards.

in plants, transcription factors control gene regulatory programs for development, growth and stress responses. transcription factors have two functions: 1) to bind dna sequences in the genome directly with a dna binding domain (dbd) or through a partner dbd-containing protein and 2) to recruit transcriptional machinery. dbds have been well characterized and can be predicted directly from amino acid sequence. in contrast, the regions of transcription factors that bind coactivator complexes, activation domains, remain poorly characterized and cannot be predicted from amino acid sequence. for example, in arabidopsis, there are 1,717 transcription factors, but only 8 known activation domains. as a consequence, when a

new genome is sequenced, models for predicting dbds can identify putative transcription factors, but there are no analogous models for predicting if these transcription factors are activators or repressors. this project will use high throughput screening methods to identify activation domains on all arabidopsis transcription factors. these data will train deep learning neural networks to predict activation domains from amino acid sequence and predict activation domains in other diverse plant species. the final portion of this project will create and validate synthetic transcription factors for engineering gene regulation in plants. these tools will expand the synthetic biology toolbox for targeted hypothesis testing of metabolic processes, engineering regulatory networks, advancing agriculture and contributing to solutions that could address environmental problems. this award was co-funded by the plant genome research program in the division of integrative organismal systems and the systems and synthetic biology cluster in the division of molecular and cellular biosciences. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Awardee: Duke University

Amount: \$1,204,813.00

Abstract: every plant begins life as a seed with one cell and one genome. in order for a plant to grow, the cells must divide and turn into different kinds of cells by turning on different genes. leaf cells turn on leaf genes; root cells turn on root genes. this process of turning genes on and off requires specialized proteins called transcription factors. transcription factors also allow plants to turn genes on or off to respond to stresses like drought or pests and pathogens. transcription factors turn genes on using specialized regions called "activation domains." the first part of this project will use technologies we developed to identify activation domains on all the transcription factors of one

widely studied plant species, arabidopsis. the data we collect will power our computational models for predicting activation domains in other plants. the final portion of this project will build synthetic transcription factors that can be used to engineer gene regulation in other plants. this research will create useful and powerful tools for plant biologists and plant breeders. this collaboration between three research teams creates a unique interdisciplinary training environment for undergraduates, graduate students, and postdoctoral research fellows. our team is committed to building a supportive environment that fosters equity, **\*\*diversity\*\*** and inclusion. the three pis come from backgrounds that have been traditionally excluded from science. two of the pis are building on the success of their nsf career awards.

in plants, transcription factors control gene regulatory programs for development, growth and stress responses. transcription factors have two functions: 1) to bind dna sequences in the genome directly with a dna binding domain (dbd) or through a partner dbd-containing protein and 2) to recruit transcriptional machinery. dbds have been well characterized and can be predicted directly from amino acid sequence. in contrast, the regions of transcription factors that bind coactivator complexes, activation domains, remain poorly characterized and cannot be predicted from amino acid sequence. for example, in arabidopsis, there are 1,717 transcription factors, but only 8 known activation domains. as a consequence, when a new genome is sequenced, models for predicting dbds can identify putative transcription factors, but there are no analogous models for predicting if these transcription factors are activators or repressors. this project will use high throughput screening methods to identify activation domains on all arabidopsis transcription factors. these data will train deep learning neural networks to predict activation domains from amino acid sequence and predict activation domains in other diverse plant species. the final portion of this project will create and validate synthetic transcription factors for engineering gene regulation in plants. these tools will expand the synthetic biology toolbox for targeted hypothesis testing of metabolic processes, engineering regulatory networks, advancing agriculture and contributing to solutions that could address environmental problems. this award was co-funded by the plant genome research program in the division of integrative organismal

systems and the systems and synthetic biology cluster in the division of molecular and cellular biosciences. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: University of Utah Particle Astrophysics Research Group Grant (VERITAS, HAWC, CTA)

Awardee: University of Utah

Amount: \$1,200,423.00

Abstract: high-energy gamma-radiation represents one of the key messengers of the extreme universe, in particular providing insight into the cosmic ray accelerators that produce the highest energy particles observed. the award supports the activities of researchers at the university of utah for on-going participation in observations and analysis of data from the high altitude water cherenkov (hawc) and veritas observatories, and the future cherenkov telescope array (cta) observatory. students and postdoctoral researchers supported by this grant will explore the origin of the high-energy gamma-radiation emitted by black holes, neutron stars, and supernova remnants. in addition, the researchers will develop ultra-high-resolution visible-light observations to accurately measure the diameters and create images of nearby stars using the veritas stellar intensity interferometry observatory. the award supports an extensive training program for undergraduate students who do not otherwise have access to extensive research facilities, and activities that explore the connections between astronomical dark skies, urban planning, bio\*\*diversity\*\* and microclimate, workforce \*\*diversity\*\*, and economic opportunity through the university's consortium for dark sky studies. recent advances in multi-wavelength analyses developed by the researchers provide a framework to explore possible astrophysical origins of galactic cosmic rays and the observed local positron flux. this includes studies of archival and new veritas observations of promising tev halo regions identified from current all-sky catalogs published by the fermi satellite observatory, and the hawc northern-sky surveys. next steps will realize improved gamma-ray

observations with the newly-developed wide-field of view schwartzchild-couder telescope and result in integrating these elements, the multi-messenger maximum likelihood analysis framework (3ml), and matched run method analysis tools to the gammapy analysis framework, for use by the future cta observatory. completing the program is a survey of stellar diameters measured in the u/v optical bands via intensity interferometry observations with the veritas telescopes that will permit development of a suite of analysis tools for imaging of o/b/a stars, cepheid variables, and binary systems. this project advances the goals of the nsf windows on the universe big idea. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: RESEARCH-PGR: Extracellular RNA Produced By Plants: What, Where, How, Who, and Why?

Awardee: Donald Danforth Plant Science Center

Amount: \$1,200,000.00

Abstract: this project investigates the role of secreted rna in the immune system of plants. the innes and meyers laboratories recently discovered that the leaves of plants accumulate rna in the spaces between cells and on their surfaces. although we usually think of rna as a molecule that can direct cells to synthesize specific proteins (e.g., the mrna in covid vaccines directs our cells to make sars-cov2 spike protein), some rnas serve other functions. analysis of the base sequences of plant extracellular rnas revealed that these rnas are diverse in sequence, but do not appear to encode proteins. the discovery of extracellular non-coding rna in plants raises two fundamental questions that this project will address: 1) how do plants secrete rna? and 2) what is the function of this rna? it takes a large amount of energy for cells to secrete rna, thus this secreted rna must benefit the plant in some way. this project will test the hypothesis that secreted rna functions to protect plants from infection by fungi and bacteria. if this hypothesis is correct, the proposed research will enable

generation of crop plants with improved immune systems that are more resistant to disease. such crops are needed to feed a growing global population in a sustainable manner, while reducing the environmental impacts of agriculture. the innes and meyers laboratories recently discovered that the apoplast of arabidopsis leaves contains abundant long non-coding rnas, including circular rnas, as well as small rnas. these rnas are bound to protein particles, which protects them against degradation. notably, this extracellular rna (exrna) is highly enriched in the post-transcriptional modification n6-methyladenine (m6a). these discoveries raise fundamental questions about plant biology: are there specific exrnas that are broadly conserved across plant species? how are exrnas secreted, and are post-transcriptional modifications central to this process? and why do plants produce exrnas? do they play a fundamental role in plant-microbe interactions? to answer these questions, exrna will be purified from the apoplast and leaf surfaces of seven diverse species: arabidopsis, soybean, tomato, lettuce, pineapple, rice, and maize, which were chosen based on their phylogenetic **diversity**, genomic resources, importance as crops, and **diversity** in physiology. these exrnas will be analyzed using both rna-seq and srna-seq, which will allow identification of rnas that are conserved between species. to assess whether m6a or other modifications are required for secretion, transgenic plants that express exrnas that lack modification sites will be tested for their secretion efficiency. to investigate additional requirements for exrna secretion, the exrna content in arabidopsis and rice plants with mutations in known rna binding proteins and secretory pathway genes will be analyzed. lastly, to assess whether exrnas contribute to immunity, mutants compromised in exrna secretion will be tested for resistance to fungal and bacterial pathogens. this award was co-funded by the plant genome research program and the plant biotic interactions program in the division of integrative organismal systems. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: SCC-CIVIC-FA Track A: A Community-Based Framework to Develop Shared Micromobility for Affordable-Accessible Housing (SMILIES)

Awardee: University of Arkansas

Amount: \$1,200,000.00

Abstract: this project presents smilies (shared micromobility for affordable-accessible housing): a community-engaged pilot project to improve accessibility to jobs and essential services for residents of affordable housing communities by leveraging the explosive growth of shared micromobility services (smm). smm includes community usage of bikes and scooters, including electric ('e') versions. affordable-accessible housing is increasingly scarce in the u.s., particularly in small and mid-sized cities in rural areas. as these cities offer only limited public transportation options, low-income residents living in those areas may struggle to access jobs and essential services. thus, transportation solutions that consider but do not rely on transit to improve the accessibility of low-income workers in small and mid-sized cities in rural areas should be investigated. smm is emerging as a popular mode for recreation in large metropolitan areas but has yet to be leveraged as an innovative solution for jobs-housing transportation in affordable housing communities. the proposed smm pilot project generated through community engagement will fill this critical gap by quantifying the impact of smm on accessibility to jobs and essential activities for affordable housing communities. this contribution is significant because it would introduce strategies and policies to guide local governments, community champions, and smm operators in efficient management of smm services while ensuring the benefits are available and accessible to low-income residents, ultimately promoting social equity. the overall objective of this project is to design and evaluate an smm system for affordable housing communities through a community-engaged research-centered pilot project. this objective will be accomplished through a community-based participatory action research (cbpar) methodology, supported with quantifiable models to estimate the impacts of smm on household travel and costs as well as the latent demand for smm services. the cbpar team for this project includes diverse stakeholders from universities, public planning and transportation

agencies, local businesses, and smm vendors. the proposed research is transformative as it will leverage community engagement to first design a community-centered smm system and then conduct real-world pilot deployments under community-defined conditions. the pilot is to be deployed in fort smith, arkansas, a mid-sized city with high incidents of poverty and racial **\*\*diversity\*\***, and a history of transportation challenges centered on access to jobs and essential services attributable to a lack of public transit. this project is part of the civic innovation challenge, which is a collaboration of nsf, department of energy vehicle technology office, department of homeland security science and technology directorate and federal emergency management agency.

this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: SCH: Explainable Learning of Heart Actions from Pulse to Broaden Cardiovascular Healthcare Access

Awardee: University of Maryland, College Park

Amount: \$1,200,000.00

Abstract: cardiovascular disease is the most prevalent cause of death. early treatment can effectively reduce the risk of sudden cardiac death, but a many cardiac issues show no obvious symptoms in the early stage and would benefit from long-term continuous cardiac monitoring to capture the intermittent and asymptomatic abnormalities of the heart. this disproportionately affects low-income and disadvantaged populations, who have limited access to affordable preventive care. an electrocardiogram (ecg) is a non-invasive gold standard for diagnosing cardiovascular diseases. although it is currently possible to obtain an instant ecg test through a special smartwatch or special attachment to a smartphone, these current options require continuous user participation and are impractical to meet the needs of long-term continuous monitoring. this project investigates a new artificial intelligence (ai) powered health solution to automated and continuous cardiac monitoring by

inferring ecg from the readily available continuous measurements, such as those sharing the same principles as in many wearable devices. the research from this project will provide insights on how to transfer the ecg-based rich knowledge base to the diagnosis of cardiovascular diseases from wearable sensors. in order to broaden participation and impact, the project will integrate research and educational activities. these include supporting the workforce development in such in-demand technical areas as machine learning and smart health, and actively engaging students in hands-on and exploratory interdisciplinary research, especially those from the under-represented groups. the project will contribute to promoting national health, welfare, and prosperity. the key research issues of inferring ecg from photoplethysmogram (ppg), which can be monitored continuously without constant user attention, include: (1) how to apply biomedical insights to model the relations between ecg and ppg; (2) how to carry out explainable learning for inferring ecg from ppg; (3) how to make a transformative expansion of public health knowledge based on the newly developed bridge between ecg and ppg; and (4) how to address a variety of diverse and practical conditions, including population **\*\*diversity\*\***, disease progression, and noise/distortions in real-world ppg sensing sources. the investigator team plans to carry out the core inference from ppg to ecg in several stages, starting with modeling the biophysical relation between ecg and ppg and representing both waveform families through the well-understood basis in the fourier family as a proof-of-concept. the team plans to utilize data next to refine the representation using dictionary learning, and incorporate a deep model when extensive data can be leveraged to provide a refined inference. the bridge between ecg and ppg enabled by explainable ai can bring unprecedented opportunities to expand smart health knowledge to benefit public health. the investigator team will work closely with a medical expert to explore ai-enabled understanding and promotion of cardiovascular health in exercise physiology, and transferring rich ecg medical knowledge base to the more user-friendly ppg domain. the team plans to embrace the opportunity of cross-disciplinary collaboration to evaluate the new capabilities in practical settings as well as promote participation and feedback from a diverse population. this award reflects nsf's statutory mission and has been

deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Frameworks: Convergence of Bayesian inverse methods and scientific machine learning in Earth system models through universal differentiable programming

Awardee: Massachusetts Institute of Technology

Amount: \$1,200,000.00

Abstract: understanding and quantifying parameter sensitivity of simulated systems, such as the numerical models of physical systems and mathematical renderings of neural networks, are essential in simulation-based science (sbs) and scientific machine learning (sciml). they are the key ingredients in bayesian inference and neural network training. seizing on the opportunity of emerging open-source earth system model development in the julia high-level programming language, this project is endowing these open-source models with automatic differentiation (ad) enabled derivative information, making these converging data science and simulation-based science tools available to a much broader research and data science community. enabling a general-purpose ad framework which can handle both large-scale earth system models as well as sciml algorithms, such as physics-informed neural networks or neural differential equations, will enable seamless integration of these approaches for hybrid bayesian inversion and bayesian machine learning. it merges big data science, in which available data enable model discovery with sparse data science, and the model structure is exploited in the selection of surrogate models representing data-informed subspaces and fulfilling conservation laws. the emerging julia language engages a new generation of researchers and software engineers, channeling much needed talent into computational science approaches to climate modeling. through dedicated community outreach programs (e.g., hackathons, minisymposia, tutorials) the project team will be working toward increasing equity, **\*\*diversity\*\***, and inclusion across the participating disciplines. the project is

developing a framework for universal differentiable programming and open-source, general-purpose ad that unifies these algorithmic frameworks within julia programming language. the general-purpose ad framework in julia leverages the composability of julia software packages and the differentiable programming approach that underlies many of the sciml and high-performance scientific computing packages. compared to most current modeling systems targeted for hpc, julia is ideally suited for heterogeneous parallel computing hardware (e.g., cuda, rocm, oneapi, arm, powerpc, x86 64, tpus). the project is bringing together expertise in ad targeted at earth system data assimilation in high performance computing environments with sciml expertise. the project team is working with the julia computing organization and package developers to ensure sustainability of the developed frameworks. the project's earth system flagship applications consist of (i) an open-source, ad-enabled ocean general circulation model that is being developed separately as part of the climate modelling alliance (clima), and (2) an open-source, ad-enabled ice flow model. each of these application frameworks is being made available to the community for science application, in which derivative (gradient or hessian) information represent key algorithmic enabling tools. these include sciml-based training of surrogate models (data-driven and/or model-informed), parameter and state estimation, data assimilation for model initialization, uncertainty quantification (hessian-based and gradient-informed mcmc) and quantitative observing system design. academic and industry partners are involved, who are using the frameworks for developing efficient power grids, personalized precision pharmacometrics, and improved eeg design. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: SCC-CIVIC-FA Track B UNUM: Unification for Underground Resilience Measures

Awardee: New York University

Amount: \$1,199,949.00

Abstract: the importance of extreme events from climate change, weather, and accidents continue to have critical impacts on infrastructure. underground infrastructures are interconnected within one another and with above ground infrastructure. these interdependencies often have cascading impacts on electric power, water, transportation and communication with extreme social and economic impacts. increasing community resilience depends upon identifying underground infrastructure data and data sharing. such underground infrastructure data are not readily known, available, or interoperable. furthermore, they are typically under multiple jurisdictions. the unum project provides a collaborative mechanism for data sharing among government, industry, utilities, and community groups with different data security requirements. two pilot areas are used within new york city, midtown east (manhattan) and sunset park (brooklyn), contrasting in the types of underground conditions, stakeholders, and demographic and economic **\*\*diversity\*\***. in stage 1, commitments to participate in data sharing were obtained from over 40 stakeholders through a data repository managed by a city agency that provide the foundation for stage 2. this stage 2 project has broader impacts in providing a roadmap and two testbeds for a data model, data needs, sharing, and security protocols for underground infrastructures transferable to other areas to improve their resilience.

goals and scope of research and methods and approaches: unum phase 2 expects to develop a methodology to standardize underground infrastructure and geological data sharing so that all subsurface utility information is made interoperable: capable of being brought together on a common basemap for integration and analysis. this will better enable (1) to identify hazard and disaster vulnerabilities, (2) devise strategies to reduce accidents and emergencies, and (3) to harden infrastructure in case of natural disasters and other large-scale threats like sea level rise and global warming. based on relationships and agreements with utilities established in unum stage 1, unum stage 2 will collect infrastructure data related to water and sewer networks (nyc dep), transit (mta), electric power (con edison and national grid), etc. subsurface utility data will be transformed into a common format, registered to nyc's photogrammetric basemap, and securely stored. the data will conform to the muddi data model now in advanced development by the open geospatial

consortium, and will be closely related to underground infrastructure asce 38 and 75 standards for engineering quality and accuracy. the unum team will co-develop with community groups art and engineering activities to improve community-based infrastructure literacy. this project is part of the civic innovation challenge which is a collaboration of nsf, department of energy vehicle technology office, department of homeland security science and technology directorate and federal emergency management agency. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Access to Innovative Education: Providing Learning Opportunities and Scholarships for Neurodivergent Students in STEM

Awardee: Landmark College

Amount: \$1,199,832.00

Abstract: this project will contribute to the national need for well-educated scientists and computer scientists by supporting the retention and graduation of high-achieving, low-income students with demonstrated financial need at landmark college. this institution is one of just two colleges in the u.s. that focuses exclusively on serving students who have a learning difference, including learning disabilities such as dyslexia, attention deficit hyperactivity disorder (adhd), and/or autism, collectively referred to as neurodiverse (nd) students. over its six-year duration, this project will provide scholarships to 36 undergraduate students who are pursuing either an associate?s or a bachelor?s degree in life sciences and/or computer science. first-year students will receive up to four years of scholarship support, and transfer and associate degree students will receive up to two years of scholarship support. the project aims to increase student persistence in stem fields by linking scholarships with effective supporting activities, including mentoring, undergraduate research experiences, internships, career preparation, and participation in robust cohort activities. with the

help of mentors and cohort activities, the scholars will outline their career goals and steps toward achieving those goals. scholars will be drawn from the landmark college student body, which consists of 100% nd students, so this project has the potential to diversify participation in stem fields and to learn how mentoring and individual development plans support retention and graduation of this student population. the project focuses on how effective mentoring leads to better outcomes for nd students in stem fields and how to form a stronger stem identity leading to positive experiences in internships and undergraduate research. the project proposes concrete strategies for increasing the number of nd students who are stem-ready for the opportunities in today's workforce. the overall goal of the project is to increase **diversity** and degree completion of nd undergraduates in stem fields. this project builds on landmark college's current institutional student supports. psychosocial, non-cognitive factors, such as academic perseverance, social skills, learning strategies, and academic mindsets, have generally been demonstrated to influence student persistence in stem. however, little is known about how these factors affect neurodiverse students at bachelor's and associate degree-granting liberal arts colleges. this project will investigate the effects of psychosocial factors on nd student persistence in stem and, more specifically, will explore how cohort support components support autistic students. this project investigates the possibility that the peer support class promotes increased student responsibility and cohort cohesion. this project will also investigate the possibility that the scholars develop a healthy disability identity and an identity in a stem field of study while persevering in their major because of participating in the mentoring activities of the project. this project has the potential to advance understanding of psychosocial factors on nd student persistence in stem and early career access. this project will be evaluated via a mixed method approach using information from the cohort activities and mentoring activities. results will be made available on the landmark college website, as well as through regional and national conferences and publications. this project is funded by nsf's scholarships in science, technology, engineering, and mathematics program, which seeks to increase the number of low-income academically talented students with demonstrated financial need who earn degrees in

stem fields. it also aims to improve the education of future stem workers, and to generate knowledge about academic success, retention, transfer, graduation, and academic/career pathways of low-income students. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: The Simpson Neutron Monitor Network

Awardee: University of Delaware

Amount: \$1,194,735.00

Abstract: this three-year collaborative project is focused on building of a network of ground-based cosmic-ray monitors, called neutron monitors (nms), operated by a consortium of three u.s. academic institutions, namely universities of new hampshire, delaware and wisconsin-river falls. invented by prof. john simpson in 1948, following his experience on the manhattan project, nms have been used to detect and measure radiation in space, starting almost ten years before the space age. they are stationed on the ground all over the globe, providing continuous measurements of cosmic radiation for over a half century. nms measure the trends and changes in the radiation levels in space, which is critical information for travel by astronauts to the moon and mars. they can also detect intense, short-term bursts of radiation from the sun that reach the ground. all this activity is driven entirely by what the sun is doing. nms are robust and reliable and have assumed a new importance in recent years when used in conjunction with the international fleet of spacecraft and with neutron monitors in other countries. now, all the nms sponsored by the u.s. are being linked into what will be the simpson neutron monitor network, which will make it more efficient to coordinate operations and science. during this three-year collaborative project, the consortium will carry out this research, teasing new information out of these heritage instruments and providing researchers around the world with up-to-date radiation climate data. cosmic rays entering the earth's

atmosphere are messengers informing us about large-scale heliosphere structure, local space environment and solar activity. they have already passed through and interacted with the interplanetary magnetic field, and they carry information of its detailed structure. some of these cosmic rays possess enough energy to reach the ground. a nm is a ground-based particle detector that records the nucleonic component in particle showers. this directly correlates with the number of high energy cosmic rays striking the earth's atmosphere. the analysis of these data is used to build an understanding of the sun's influence on the solar system. because of the large detector volume exploited by ground-based stations, neutron monitors remain the state-of-the-art instrumentation for measuring rigidity  $>1\text{gv}$  cosmic rays. the programmatic linking of these instruments run by the universities of new hampshire, delaware and wisconsin-river falls will secure a continuity of quality data for the global community, as called out in the national space weather plan and congressional legislation. the data from these instruments are used by many, including, space weather predictors, industry, space scientists, homeland security and hydrologists. the nm stations span a wide range of latitudes, from the south pole to the arctic regions. the contributors to the nm signal include cosmic rays from the galaxy that are heavily modulated by solar activity and from the sun itself in the form of high energy bursts of protons. the variability of these agents reveals conditions in interplanetary space, general solar activity and the fundamental processes that produce cosmic rays throughout the universe. with today's computing resources, we better understand how these instruments detect radiation, and the consortium will thus be able to extract new information from these workhorse devices. this will shed new light on how the distribution of cosmic rays varies with time, geography and particle energy. the consortium will study how to permanently secure the operations of the monitor network and intelligent ways of expanding the network to complement those at existing sites. the education and outreach goals of the project include a research position for a postdoc, a wide variety of opportunities and experiences for undergraduates, as well as opportunities for high school and elementary school students. the research and epo agenda of this collaborative project supports the strategic goals of the ags division in discovery, learning,

**\*\*diversity\*\***, and interdisciplinary research. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: A Data-Driven Employer-Academia Partnership for Continual Computing Curricular Change

Awardee: University of Alabama Tuscaloosa

Amount: \$1,188,256.00

Abstract: this project aims to serve the national interest by improving the supply of well-prepared computer science professionals capable of addressing the needs of american employers in the public and private sectors. this project intends to build a national partnership between employers and academia to help identify and mitigate gaps between the competencies of computing graduates and the expectations of potential employers. the project will survey computer science educators and practitioners to develop a model that defines the competencies expected by potential employers. the project team then plans to test the model at three institutions of higher education in alabama ? the university of alabama, tuscaloosa, tuskegee university, and shelton state community college. finally, the project team intends to develop tools and methods for institutions to identify and implement competency-based educational approaches for computer science across the nation. the project plans to use three interconnected strands of evidence-based activities to institute transformational change in the involved communities. first, a national strand will engage u.s. faculty in developing competency-based curricula informed by industry practitioner feedback. second, a local pilot strand intends to create transformative curricular change based on student competencies using an evidence-based change model in the three alabama institutions. sociologists and computing faculty on the team will help to understand, predict, and reduce barriers to competency-based employment of computing graduates from marginalized communities in the heart

of the impoverished alabama black belt. the unique perspective relative to **\*\*diversity\*\***, equity, and inclusion needs should serve as a model for other computing departments. the third strand will develop competency-based surveys for practitioners and academics to identify and refine specific competencies that are hoped to drive continual curricular change. outcomes, including the change process, national workshops, and experiences from the local process will help with transferability in the computing education community. in addition to informing curricula, the project will provide valuable data for educational researchers to help close the gap between employers and higher education. finally, as the competency approach to curricular design is relatively new in computing and engineering disciplines, lessons from this project will have the potential to transform curricular review and design in other stem disciplines. the nsf iuse: ehr program supports research and development projects to improve the effectiveness of stem education for all students. through the institutional and community transformation track, the program supports efforts to transform and improve stem education across institutions of higher education and disciplinary communities. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: RTG: Computational Mathematics for Data Science

Awardee: Emory University

Amount: \$1,188,174.00

Abstract: computational and data-enabled science has become the third pillar of science, completing theory and experimentation. its success has been fueled by breakthroughs in scientific computing, the explosion of available data, and our ability to formulate mathematical models and calibrate them to measured data. recent success stories range from numerical weather prediction, which has seen tremendous achievements in accuracy over the past years, to speech recognition, which has dramatically improved in the last decade by systematically learning from data. the aim of this project

is to implement a comprehensive vertically integrated research training group (rtg) on the central theme of computational mathematics for data science. in addition to being areas of fundamental and strategic importance to the united states (e.g., for the development of new medicines, technologies, and defense capabilities), both computational mathematics and data science are areas that can have a tremendous societal impact and will attract a broad range of students. the rtg themes of this project include applications ranging from statistical data assimilation to machine learning, which are among the most transformative technologies of our times and have captured substantial public interest with many potential applications from drug discovery to driverless cars. despite many advances, there still is a pressing need for more mathematical theory and rigor, which provides ample research opportunities for all levels of mathematicians, from undergraduate students, graduate students, postdocs, and senior scientists. this project will support 3 graduate students per year, 1.5 undergraduate students per year and at least 1 postdoc per year. at its core, data science uses mathematical methods and computational approaches to extract knowledge and information from data. harnessing the data revolution requires new mathematical breakthroughs in the form of theory, models, and computational algorithms. breakthroughs are particularly needed to enable mathematicians and application scientists to analyze and synthesize larger and more complex datasets in an effective, reliable, and explainable manner. to this end, the research conducted in this project will unify and further develop the mathematical theory and computational tools used in applications ranging from data assimilation to machine learning. this comprehensive approach will be based on knowledge from, and make novel contributions to mathematics, computational science, and data science. particular focus will be on the mathematics of deep learning and data assimilation and their application in impactful areas of medicine (cardiac modeling, medical imaging), the weather and environment (hurricane storm surge modeling), and disease outbreak modeling. common threads in these areas are their mathematical foundations, most importantly differential equations, optimization, linear algebra and advanced techniques from computational science, such as parallel and distributed computing. this rtg program is anchored

around year-long research themes that include one or more of the above mentioned core research themes. training will be multi-faceted, to include education, potential career skills and experiences, soft skills, scientific integrity, and promoting an appreciation for \*\*diversity\*\*. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Leveraging the Power of Reflection and Visual Representation in Middle-Schoolers' Learning During and After an Informal Science Experience

Awardee: Gulf of Maine Research Institute

Amount: \$1,186,630.00

Abstract: this project addresses a longstanding problem in informal science education: how to increase the likelihood of consequential science, technology, engineering, and mathematics (stem) learning from short duration experiences such as field trips. although informal learning experiences can greatly contribute to interest in and knowledge of science, there is a shared concern among educators and researchers that students may have difficulty recalling and using scientific information and practices emphasized during these experiences, even though doing so would further their science learning. nonetheless, science learning is rarely, if ever, a "one-shot deal." children acquire knowledge about science cumulatively across different contexts and activities. therefore, it is important that informal science learning institutions identify effective practices that support the consolidation of learning and memory from exhibit experiences to foster portable, usable knowledge across contexts, such as from informal science learning institutions, to classrooms, and homes. to this end, this research in service to practice project seeks to harness the power and potential of visual representations (e.g., graphs, drawings, charts, maps, etc.) for enhancing learning and encouraging effective reflection during and after science learning experiences. the project promises to increase learning for the 9,000+ 5th and 6th grade students from across the rurality and growing

**\*\*diversity\*\*** of the state of maine who annually participate in labventure, a 2.5-hour exploration of the gulf of maine ecosystem at gulf of maine research institute. the research will provide new and actionable informal science learning practices that promote engagement with visual representations and reflection, and science understandings that can be applied broadly by informal science institutions. this project is funded by the advancing informal stem learning (aisl) and the discovery research prek-12 (drk-12) programs. it supports the aisl program goals to advance new approaches to, and evidence-based understanding of, the design and development of stem learning in informal environments. it supports the drk-12 program goal of enhancing the learning and teaching of stem by prek-12 students and teachers. the project is grounded in the idea that visual representations, including drawings, can both enhance science learning and encourage reflection on doing science that can support extension of that learning beyond a singular informal science experience. the project uses design-based research to address the following research questions: (1) does reflection during an informal science learning experience promote students' retention and subsequent use of science information and practices that are part of the experience? (2) does interpreting and constructing visual representations, such as drawings, improve students' understanding and retention of information, and if so, how and when? and (3) does combining visual representations and narrative reflections confer benefits on students' science learning and engagement in science practices both during the informal learning experience, and later in their classrooms and at home? these questions will be pursued in collaboration with practitioners (both informal educators and classroom teachers) and a diverse team of graduate and undergraduate student researchers. approximately 600 student groups (roughly 3000 individual students) will be observed during the labventure experience, with further data collection involving a portion of these students at school and at home. the project will yield resources and video demonstrations of field-tested, empirically based practices that promote engagement with visual representations and reflection, and science understandings that can travel within students' learning ecosystem. in support of broadening participation, the undergraduate/graduate student researchers will gain wide understanding and

experience connecting research to practice and communicating science to academic and nonacademic audiences. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Leveraging the Power of Reflection and Visual Representation in Middle-Schoolers' Learning During and After an Informal Science Experience

Awardee: Gulf of Maine Research Institute

Amount: \$1,186,630.00

Abstract: this project addresses a longstanding problem in informal science education: how to increase the likelihood of consequential science, technology, engineering, and mathematics (stem) learning from short duration experiences such as field trips. although informal learning experiences can greatly contribute to interest in and knowledge of science, there is a shared concern among educators and researchers that students may have difficulty recalling and using scientific information and practices emphasized during these experiences, even though doing so would further their science learning. nonetheless, science learning is rarely, if ever, a "one-shot deal." children acquire knowledge about science cumulatively across different contexts and activities. therefore, it is important that informal science learning institutions identify effective practices that support the consolidation of learning and memory from exhibit experiences to foster portable, usable knowledge across contexts, such as from informal science learning institutions, to classrooms, and homes. to this end, this research in service to practice project seeks to harness the power and potential of visual representations (e.g., graphs, drawings, charts, maps, etc.) for enhancing learning and encouraging effective reflection during and after science learning experiences. the project promises to increase learning for the 9,000+ 5th and 6th grade students from across the rurality and growing **\*\*diversity\*\*** of the state of maine who annually participate in labventure, a 2.5-hour exploration of

the gulf of maine ecosystem at gulf of maine research institute. the research will provide new and actionable informal science learning practices that promote engagement with visual representations and reflection, and science understandings that can be applied broadly by informal science institutions. this project is funded by the advancing informal stem learning (aisl) and the discovery research prek-12 (drk-12) programs. it supports the aisl program goals to advance new approaches to, and evidence-based understanding of, the design and development of stem learning in informal environments. it supports the drk-12 program goal of enhancing the learning and teaching of stem by prek-12 students and teachers. the project is grounded in the idea that visual representations, including drawings, can both enhance science learning and encourage reflection on doing science that can support extension of that learning beyond a singular informal science experience. the project uses design-based research to address the following research questions: (1) does reflection during an informal science learning experience promote students' retention and subsequent use of science information and practices that are part of the experience? Title: DMREF/GOALI/Collaborative Research: Physics-Informed Artificial Intelligence for Parallel Design of Metal Matrix Composites and their Additive Manufacturing

Awardee: Georgia Tech Research Corporation

Amount: \$1,177,594.00

Abstract: this designing materials to revolutionize and engineer our future (dmref) research enables physics-informed artificial intelligence (ai) design of metal materials reinforced with ceramic particles (metal matrix composites) and their additive manufacturing (3d printing). such materials can exhibit superior mechanical performances at higher temperatures relative to the same metal material without ceramic reinforcements. additive manufacturing provides unprecedented fabrication capability for high performance, lightweight structural components made from metal matrix composite materials. however, the design of metal matrix composites and their additive manufacturing is largely performed with expensive, time consuming trial and error methodologies; quality assurance of such parts is similarly challenged. ai-guided design and qualification of materials and their manufacturing can significantly lower the time and cost barriers to such technologies. the basic research performed in this program will fill critical gaps to enable ai discovery and optimization of these materials and their manufacturing toward reducing deployment times and costs by half, to meet the materials genome initiative vision. the outreach programs and **\*\*diversity\*\***, equity, and inclusion plans include ai manufacturing course curricula spanning kindergarten - graduate which include example problems and tools developed from this program. atlanta and salt lake city high school teachers and students from underrepresented minority populations will receive hands-on experience and instruction in these curricula. the research

maintains and expands robust programs supporting fundamental research in alloys, ceramics, and their composites; support modalities for free-flowing interactions among universities (georgia tech and utah), start-up ventures (goali partner elementum 3d), and national laboratories (air force research laboratory); expand investments in automated materials manufacturing research to ensure the u.s. is the leader in the field by 2030; all using, when appropriate, computational methods, data analytics, machine learning, and autonomous experimental 3d characterization. this research program enables physics-informed artificial intelligence (ai) - driven parallel design of metal matrix composites and their additive manufacturing. the concept of ai that discovers and optimizes new materials and their additive manufacturing (am) in parallel promises to further revolutionize am but is yet to be realized. basic research is to enable autonomous ai discovery and optimization of materials and their manufacturing toward reducing deployment times and costs by half, to meet the materials genome initiative vision. five critical data-driven algorithmic gaps will be filled: 1) data analysis-interpretation-curation algorithms to enable automatic, pedigreed data curation from requisite process-structure-property data sources. 2) algorithms that automate data cleaning and concatenation of databases so that ai can modify and append the data spaces when new data sources or data features are incorporated into a research problem. 3) algorithms that automate data feature mapping across multiple length and time scales to complete process-structure-property data ontologies. 4) data feature engineering algorithms that improve the ai performance. 5) process-structure-property machine learning models that learn global relationships across multiple nested submodels. physics-based models and experiments will be advanced to predict and verify their utility in discovering and optimizing metal matrix composites and their additive manufacturing at multiple length and time scales. high throughput one-dimensional, two-dimensional, and three-dimensional characterization data analyses will be automated. goali partner elementum 3d will provide a techno-economic baseline study of commercializing a new metal matrix composite for additive manufacturing to be used as an overall assessment metric for the advancements made in this program. the development of a new am test artifact will benefit researchers around the globe.

the protocols and standards developed for automating data workflows can benefit materials science and engineering researchers around the world by increasing access to high-throughput and high-fidelity data sources, including machine learning models and ai knowledge systems, for all kinds of materials and manufacturing processes. this project is jointly funded by the division of civil, mechanical and manufacturing innovation (cmmi) in the directorate for engineering (eng), the division of information and intelligent systems (iis) in the directorate for computer and information science and engineering (cise), and the division of materials research (dmr) in the directorate for mathematical and physical sciences (mps). this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Bees of the World - Phylogenomics, Biogeography, and Evolution of Host-Plant Associations

Awardee: Washington State University

Amount: \$1,176,747.00

Abstract: bees are vitally important to agriculture, food security, and the preservation of natural ecosystems due to their pollination services. over 85% of the 325,000 flowering plant species on the planet depend on animal pollination and the vast majority is carried out by bees. in the u.s.a. alone

bees are responsible for the commercial production of 130 crop plants, generating over \$11 billion in annual revenue. the value of bees to nature and human well-being is abundantly clear. the partnership between bees and flowering plants formed over 100 million years ago, and since that time, bees have radiated globally into an astounding 20,000+ different species, many of which are specialist pollinators of particular plant species or families. the study of bee bio\*\*diversity\*\* is urgently needed because there is growing evidence that some bee species are in decline and baseline knowledge of bee \*\*diversity\*\*, distribution, and family relationships is incomplete. the bees of the world project has the potential to significantly improve knowledge of bee bio\*\*diversity\*\* and to establish a guide to interpret key traits of bees, such as their host-plant associations. by utilizing recent advances in dna sequencing technology, a comprehensive tree-of-life for bees will be generated for the first time, providing a framework from which to study bee \*\*diversity\*\* and their relationships with plants. to disseminate results and general bee knowledge, the project will engage in multiple outreach efforts with professional and non-professional audiences. activities include creation of a virtual bee course, teaching of a molecular methods workshop, and, in collaboration with the natural history museum of utah, development of exhibits and youth education activities focused on pollinators. the project will use cutting edge molecular and analytical methods and engage a global network of collaborators to assemble a comprehensive phylogenomic dataset for bees. the project aims are to: (1) resolve remaining uncertainties in higher-level bee phylogeny and classification, (2) incorporate fossils to reconstruct the global biogeographic history of bees, revealing the origin and spread of bee \*\*diversity\*\* over time, and (3) analyze patterns of host-plant use across bees and for targeted clades at lower taxonomic levels, revealing how host-plant specialization has evolved and impacted rates of diversification in bees. to resolve the phylogeny of bees with improved confidence, the research team will use next-generation dna sequencing approaches and novel laboratory methods to sequence bee species from across the globe. the project will generate low coverage genomes for most bee genera and ultraconserved element (uce) data for over 3,000 species, filling in sampling gaps. the resulting bee phylogeny will serve as a

framework to study bee classification, biogeography, and host-plant evolution. comprehensive databases of bee fossil, distribution, and host-plant information will be created and made available to other researchers. combining results from each component of the project will provide a comprehensive understanding of how bees have diversified and dispersed over time and how their partnership with plants has shaped their evolutionary trajectory. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Accessible Computational Thinking in Elementary Science Classes within and across Culturally and Linguistically Diverse Contexts

Awardee: University of Maryland, College Park

Amount: \$1,172,781.00

Abstract: currently, students who are white, affluent, and identify as male tend to develop a greater interest in and pursuit of science and computing-related careers compared to their black, latinx, native american, and female-identifying peers. yet, science, computing, and computational thinking drive societal decision-making and problem-solving. the lack of cultural and racial **\*\*diversity\*\*** in science and computing-related careers can lead to societal systems and decision-making structures that fail to consider a wide range of perspectives and expertise. teachers play a critical role in preparing students to develop these skills and succeed in a technological and scientific world. for this reason, it is crucial to investigate how teachers can help culturally and linguistically diverse students develop a greater understanding of and interest in science and computers. this research project aims to enhance elementary teacher education in science and computational thinking pedagogy through the use of culturally relevant teaching, i.e. teaching in ways that are relevant to students from different cultural and linguistic backgrounds the project will support 60 elementary teachers in summer professional development and consistent learning opportunities during the

school year to learn about and enact culturally relevant computational thinking into their science instruction. in doing so, the project aims to increase both the quantity and quality of computing experiences for all elementary students and support nsf's commitment in broadening participation in the stem workforce. the project will also produce resources, measures, and tools to support elementary teachers to do this kind of work, which will be shared with other stem researchers and teacher educators. the goal of this research project is to design and promote teaching practices that integrate computational thinking in the elementary science classroom in culturally relevant ways. this project will seek to empower practicing elementary teachers' approaches to meaningfully and effectively integrate and adapt computational thinking into their regular science teaching practice so that all students can access the curriculum. it will also explore the impact of these approaches on student learning and self-efficacy. the scope of this project will include working with multiple highly distinct school settings in maryland, arizona, and washington dc across three years, reaching approximately 60 elementary teachers and 1,200 students. to achieve the project objectives, the research team will leverage concurrent mixed methods approaches that include teacher and student interviews, reflections, observations, descriptive case study reports as well as regression and multilevel modeling. the project's findings will inform the field's understanding of: (a) teachers' conceptualization of computational thinking; (b) the barriers elementary teachers encounter when trying to integrate computational thinking with culturally relevant teaching practices; (c) the types of support that are effective in teacher professional development experiences and throughout the school year; and (d) the development of a cohort of teachers that can maintain integration efforts in different districts. the discovery research prek-12 program (drk-12) seeks to significantly enhance the learning and teaching of stem subjects by prek-12 students and teachers, through research and development of innovative resources, models and tools. projects in the drk-12 program build on fundamental research in stem education and prior research and development efforts that provide theoretical and empirical justification for proposed projects. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the

foundation's intellectual merit and broader impacts review criteria.

Title: MRI: Acquisition of an ultrahigh resolution mass spectrometry system to enable metaproteomics experiments to support microbiome research

Awardee: Colorado State University

Amount: \$1,167,241.00

Abstract: an award is made to colorado state university (csu) to purchase state-of-the-art instrumentation to study the microbiome. the instrument will be housed in and managed by the csu analytical resources core bioanalysis and omics center (arc-bio) at the fort collins campus, which ensures that this shared resource is equally available to all csu students ? including students at the csu campus in pueblo, co, a federally designated minority serving institution. the requested instrument will be used to support a hands-on undergraduate research experience in microbiological sciences. the pi team, highly regarded leaders in microbiome and analytical sciences, will disseminate knowledge derived from this instrument through both formal and informal methods, including development of graduate and undergraduate coursework and lectures, laboratory tours, graduate committee membership, and undergraduate employment and training. a hands-on workshop involving the graduate student microbiome club and the student bioinformatics club is planned to introduce metaproteomic concepts and nurture a well-educated user base for this instrument. these educational activities offer improved stem educational opportunities at every academic level within csu in a manner that reflects csu's **\*\*diversity\*\***. training in modern mass spectrometry helps to ensure a globally competitive stem workforce valued by both academic and corporate employers. the ?microbiome? can be defined as a community of microorganisms in a particular environment (e.g. human, animal, soil, etc.). microbiome studies are primarily facilitated using 16s rrna or metagenomics sequencing to identify the bacterial components present in a given microbial community. however, this type of analysis cannot measure functional changes to microbial

communities (e.g. what are the bacteria doing?). proteins represent the biologically functional output of genes, and proteomics is the analytical technique used to characterize an organism's functionality. by extension, metaproteomics approaches provide thousands of measurements of protein composition and concentration from a community of organisms. metaproteomics has historically been limited by mass spectrometry technology and computational challenges. significant advancements have been achieved in both of these areas, opening the potential for more researchers to incorporate metaproteomics approaches in their studies. researchers at csu are interested in understanding the functional and structural basis of microbiome biology and ecology, with application to research fields including human, animal, plant and soil biology, ecology, and biofuels. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: GCR: Growing a New Science of Landscape Terraformation: The Convergence of Rock, Fluids, and Life to form Complex Ecosystems Across Scales

Awardee: University of Arizona

Amount: \$1,158,103.00

Abstract: the u.s. and the world today face the increasingly urgent question of how to better understand and manage complex physical-biological systems in order to address pressing problems such as: restoration of degraded landscapes, sustainable management of ecosystem services, including water cycling and supply, ecosystem nutrition, bio\*\*diversity\*\*, carbon sequestration in the face of global change, and eventually, terraforming planets beyond earth. at the root of these problems is the fundamental question of landscape terraformation: how does life expand and sustain itself, in increasingly complex and symbiotic forms, across landscapes at multiple scales to transform bare rock into complex multi-function ecosystems? this growing convergence research team of earth scientists (hydrologists, geochemists), biologists (evolutionary genomicists, ecosystem ecologists), and social scientists (anthropologists who study cultures of science) will leverage a unique and powerful ?convergence instrument? -- university of arizona?s landscape evolution observatory, consisting of three large experimental hillslopes at biosphere 2 -- to both reveal key mechanisms of landscape terraformation and catalyze new ways of interdisciplinary thinking to empower and diversify this next generation of scientists to achieve convergence research. the central investigation of this work is of how small scale hydrological, geochemical, ecological and evolutionary processes interact to create emergent landscape-scale terraformation, across three stages of biological complexity: from simple lithotrophic microbial communities (including microbial crusts), to non-vascular plants (mosses without roots), to vascular plants with roots and sophisticated hydraulic architectures. experiments will test model representations of water flow through landscapes, its effects on the transformation of rock via weathering at different scales, and

thence, feedbacks which modify those landscapes and their biological habitability. at the same time, the composition and function of organisms as they colonize barren landscapes and develop symbiotic associations (especially for n fixation) will be manipulated to select from biological **\*\*diversity\*\*** in genes, traits, and functions, in order to identify the biological feedbacks which simultaneously transform hydrological and geochemical processes. in the process, convergence research will be studied, understood, and reflected through a novel, social science-based ?cultures of convergence science? investigation of the entire team in an ethnographic inquiry designed to identify practices conducive to successful convergence research. this proposal is supported in part by the critical zone collaborative network program. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Investigating the genetic correlation hypothesis of signal-preference evolution

Awardee: Cornell University

Amount: \$1,145,645.00

Abstract: the genetics of behavior is a frontier in many respects, and its understanding is fundamental to many areas of biology, including conservation, sustainability and human health. this work explores the genetic correlations that may exist between male calling behavior and female mate choice in *laupala kohalensis*, a cricket species in hawaii, and how this correlation impacts the expression of male behavior and the associated female preference for calls. undergraduate, graduate and post-doctoral students supported by this project will gain research experiences in integrating behavioral and genetic/genomic studies related to animal behavior questions in natural populations. rigorous cross-training in these areas has tremendous potential for making transformative progress in the study of behavior. students will gain experiences in experimental design, field collecting, animal husbandry, behavioral measurements, dna manipulations, sequencing and bioinformatics. students working on the project will also gain outreach experiences, including projects with hawaii volcanoes national park, where we will develop public exhibits to teach about the unique hawaiian bio\*\*diversity\*\* and their scientific importance, as well as studies of the interactions between invasive species and hawaiian bio\*\*diversity\*\*. public lectures will be planned to participate in the science in the park series. our work also provides leadership on how to study behavior at multiple levels of analysis and to value the role of non-model organisms in the study of behavioral \*\*diversity\*\* and genetics. our work will provide vital genome sequence data from a non-model genome, specifically that contains genes involved in rhythmic behaviors with many analogs across diverse forms of life.

theoretical work supports the concept that genetic correlations underlying diverse behaviors are vital to healthy population function such that these genetic structures can be engaged rapidly during changing environments. while theory demonstrates its deep relevance, the presence of genetic correlation is empirically not well-established. our proposal offers a strong empirical system, sound methodology and exciting technological advancements aimed at producing a complete study of genetic correlation in the species *laupala kohalensis*. the present proposal uses a design that contrasts contributions to

genetic correlation from female preference and the physical location of genes underlying male and female behaviors in natural populations. the genetic correlation will be further probed in a selection experiment on male song, and its indirect effect on female acoustic preference. the proposed work will capitalize on a powerful experimental design to produce genome wide sequence data that can characterize the response to selection, in order to identify the genes underlying these behaviors and test the hypothesis that the responding intraspecific genetic variation shares the same genetic basis found between species. in the process of doing this research, we will also estimate natural levels of linkage disequilibrium across the genome in *laupala kohalensis* in relation to the location of acoustic behavior genes. understanding the genetics and identifying the genes underlying these traits will provide a much-needed empirical basis on which to judge numerous theoretical models. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Awardee: Syracuse University

Amount: \$1,135,333.00

Abstract: the national science foundation (nsf) graduate research fellowship program (grfp) is a highly competitive, federal fellowship program. grfp helps ensure the vitality and **\*\*diversity\*\*** of the scientific and engineering workforce of the united states. the program recognizes and supports outstanding graduate students who are pursuing research-based master's and doctoral degrees in

science, technology, engineering, and mathematics (stem) and in stem education. the grfp provides three years of financial support for the graduate education of individuals who have demonstrated their potential for significant research achievements in stem and stem education. this award supports the nsf graduate fellows pursuing graduate education at this grfp institution. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Examining Training Environments and Career Outcomes of Interdisciplinary STEM PhD Students

Awardee: Ohio State University

Amount: \$1,134,496.00

Abstract: this collaborative project with ohio state university as the lead institution and indiana university and cornell university as partners examines the career outcomes across employment sectors of interdisciplinary graduate students, the environments in which they are trained, and how those environments relate to career outcomes. the investigators will use and expand an emerging infrastructure of data and measures to conduct a rich, multilevel analysis of individual career paths in the transition from graduate training to the workforce in the context of supply and demand factors that exist throughout a researcher's career. the investigators will (1) study how the characteristics of interdisciplinary researchers compare to disciplinary researchers and how the structure of the teams and networks in which they train compare, (2) develop a range of novel measures of early career outcomes to study how outcomes relate to training environments of disciplinarians and interdisciplinarians, and (3) study how outcomes vary across disciplines and by market demand. the project will enable young researchers to be better informed about the career outcomes of interdisciplinary researchers and provide actionable information to improve the training environments for these researchers. the project will be implemented using the emerging umetrics

infrastructure, and the data and metrics that the investigators develop on interdisciplinarity will flow back into the umetrics data infrastructure and made accessible for other researchers through the virtual enclave run by the institute for research on innovation and science at the university of michigan. the research will include three tasks. task 1: develop rich multi-faceted measures to identify interdisciplinarity among stem doctoral students and researchers. a wide range of integrated data resources will be used to operationalize ?interdisciplinarity?. investigators will generate field-based measures, citation-based measures, field transition measures, and text-based measures that will be cross-validated to trace the interdisciplinarity of research trajectories post graduation. task 2: describe the environments in which interdisciplinary graduate students train. investigators will describe a range of dimensions of training environments and how they relate to interdisciplinary research, including advisors, teams, team size and composition, team **\*\*diversity\*\***, and funding mechanism. task 3: estimate a wide range of career outcomes for interdisciplinary phd recipients and the role of supply and demand in shaping outcomes. data will examine whether interdisciplinary research is mostly induced by discoveries in new fields that open new avenues of research or whether the need for interdisciplinary research induces these discoveries. the project will expand an evolving data infrastructure for investigating stem workforce development. the project is supported by the ehr core research program that funds fundamental research focused on stem learning and learning environments, broadening participation in stem fields, and stem workforce development. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: SCH: Enhanced detection of impending problem behavior in people with intellectual and developmental disabilities through multimodal sensing and machine learning

Awardee: Vanderbilt University

Amount: \$1,103,997.00

Abstract: children with intellectual and developmental disabilities (idd) are at increased risk of showing ?problem behavior? that place them at risk of getting hurt, removed from the classroom, or hospitalized. approximately 1 in 6 children and adolescents in the united states are diagnosed with idd and half of them experience some form of problem behavior. therapists trained in applied behavior analysis, or aba, can help determine why problem behavior happens and how to prevent it. these therapists watch children, try to evoke problem behaviors by changing a child?s environment, then try things that might change behavior, and see if the behavioral data changes. because problem behavior can be triggered during this process, this strategy sometimes put them or their patient at risk. it also takes a lot of time. wearable technology and advanced computational strategies could help increase the safety and helpfulness of strategies to prevent problem behavior. specifically, small sensors worn in clothing or on the wrist could provide data about a child?s body, or ?physiological responses,? like heart rate or sweat. machine learning can then be used to determine what combination of body signals imply a problem behavior is about to happen. this project has two stages. in the first stage, the team will design new sensors that detect biological signals such as sweating, motion, and heart rate. the team will then measure how well these sensors work. this includes asking people with idd what they think about the sensors. based on that input, the team will change the sensors and then use them in a larger study. the goal is to test whether the system can predict problem behavior, how well it works when used in the real-world with real therapists, and what users think about the system. results of this study will help researchers and practitioners understand if this kind of wearable technology is helpful and acceptable as part of supporting people with problem behavior and idd. this project proposes to integrate transdisciplinary expertise in cutting-edge wearable sensing, affective computing, machine learning, and behavioral and clinical science to enhance and transform existing models of behavioral intervention for problem behaviors in children and adolescents with idd. problem behaviors, including self-injury, aggression, property destruction, and wandering not only can cause serious injury or death, but also interfere with the ability to participate in school, home, and other community

settings. in the context of problem behavior and idd, this project will fundamentally advance the scientific and the technological methodologies of multimodal wearable sensing-based design of predictive machine learning models. the two research thrusts are: (1) design of multimodal sensor framework; and 2) real-time precursor prediction. across these thrusts, the project will make fundamental scientific and technological advancements in: (i) a low-power, open-access, user-centric wearable sensor framework that can sense physiological responses and gestures to be used for affective computing; and (ii) a set of novel, clinically grounded, semi-supervised machine learning models to predict problem behavior that can be used by behavioral interventionists in real-time. an important novelty of this research that separates it from existing work in the field is that the team proposes to address the detection of problem behavior through its precursors, rather than the behaviors themselves, with the goal of increasing the safety and efficiency of sessions. these scientific and technological advancements will be created within a state-of-the-art clinical and behavioral science framework. the proposed work will foster interdisciplinary research in engineering and health sciences. the team proposes a number of outreach and educational activities that will have broader impact in stem education: i) involve individuals with asd directly in the research through the frist center for autism & innovation?s neuro\*\*diversity\*\* corps; ii) provide interdisciplinary training opportunities for early stage clinical scientists; iii) provide research opportunity to high school, undergraduate, and graduate students; iv) provide research opportunity to high school teachers; v) bring research into the classroom; and vi) disseminate the research through seminars, presentation, and publication. emphasis will be placed on recruiting candidates from minority and underrepresented groups to improve \*\*diversity\*\* in stem. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: EVOLUTIONARY CONFLICT AND PHENOTYPIC DIVERSITY IN SOCIETIES

Awardee: Georgia Tech Research Corporation

Amount: \$1,100,989.00

Abstract: biological organisms display remarkable **diversity** in form and function. for example, individuals frequently belong to distinct functional classes, such as the male and female sexes. however, because individuals within species generally possess the same set of genes, the development of distinct classes is expected to be constrained. the goal of this research is to study the constraints on the development of distinct classes in social insects. social insects represent excellent study systems because insect societies are composed of distinct functional classes such as the queen, worker, and male castes. in addition, social insects, such as bees, wasps, ants, and termites, have great ecological and economic importance. this research will analyze the physical forms, gene functions, and genome sequences of social insects to understand the importance of the shared genome on the development of distinct classes. the research will also include several broader impacts that will extend the influence of this research to educational activities aimed at training and educating the public. this research is significant because it will provide insight into the genetic mechanisms associated with the development of distinct functional classes and the causes of organismal **diversity** within species. phenotypic **diversity** is a hallmark of metazoan taxa. however, phenotypic evolution is constrained by intralocus conflict, which occurs when individuals within species possess traits that have a common genetic architecture. this research will explore intralocus conflict in social insects and determine if conflict has constrained phenotypic evolution in societies. study of genetic conflict in societies is particularly interesting because individuals may experience both intralocus caste conflict, which occurs between the castes, as well as intralocus sexual conflict, which occurs between the sexes. this research will test intralocus conflict theory. first, the research team will determine genetic correlations for morphological traits in queens, males, and workers. second, intralocus conflict will be studied at the molecular level by testing predictions about genetic correlations for gene expression phenotypes. finally, evidence for intralocus conflict will be detected by examining population genomic variation. this program will also promote

teaching, training, and learning. research will be incorporated into university classes, city-wide activities, and disseminated in the popular media. overall, this research program will result in one of the most thorough empirical investigations of intralocus conflict theory and provide insight into the mechanisms affecting phenotypic **\*\*diversity\*\***. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: RESEARCH-PGR: Extracellular RNA Produced By Plants: What, Where, How, Who, and Why?

Awardee: Indiana University

Amount: \$1,100,000.00

Abstract: this project investigates the role of secreted rna in the immune system of plants. the innes and meyers laboratories recently discovered that the leaves of plants accumulate rna in the spaces between cells and on their surfaces. although we usually think of rna as a molecule that can direct cells to synthesize specific proteins (e.g., the mrna in covid vaccines directs our cells to make sars-cov2 spike protein), some rnas serve other functions. analysis of the base sequences of plant extracellular rnas revealed that these rnas are diverse in sequence, but do not appear to encode proteins. the discovery of extracellular non-coding rna in plants raises two fundamental questions that this project will address: 1) how do plants secrete rna? and 2) what is the function of this rna? it takes a large amount of energy for cells to secrete rna, thus this secreted rna must benefit the plant in some way. this project will test the hypothesis that secreted rna functions to protect plants from infection by fungi and bacteria. if this hypothesis is correct, the proposed research will enable generation of crop plants with improved immune systems that are more resistant to disease. such crops are needed to feed a growing global population in a sustainable manner, while reducing the environmental impacts of agriculture. the innes and meyers laboratories recently discovered that

the apoplast of arabidopsis leaves contains abundant long non-coding rnas, including circular rnas, as well as small rnas. these rnas are bound to protein particles, which protects them against degradation. notably, this extracellular rna (exrna) is highly enriched in the post-transcriptional modification n6-methlyadenine (m6a). these discoveries raise fundamental questions about plant biology: are there specific exrnas that are broadly conserved across plant species? how are exrnas secreted, and are post-transcriptional modifications central to this process? and why do plants produce exrnas? do they play a fundamental role in plant-microbe interactions? to answer these questions, exrna will be purified from the apoplast and leaf surfaces of seven diverse species: arabidopsis, soybean, tomato, lettuce, pineapple, rice, and maize, which were chosen based on their phylogenetic **\*\*diversity\*\***, genomic resources, importance as crops, and **\*\*diversity\*\*** in physiology. these exrnas will be analyzed using both rna-seq and srna-seq, which will allow identification of rnas that are conserved between species. to assess whether m6a or other modifications are required for secretion, transgenic plants that express exrnas that lack modification sites will be tested for their secretion efficiency. to investigate additional requirements for exrna secretion, the exrna content in arabidopsis and rice plants with mutations in known rna binding proteins and secretory pathway genes will be analyzed. lastly, to assess whether exrnas contribute to immunity, mutants compromised in exrna secretion will be tested for resistance to fungal and bacterial pathogens. this award was co-funded by the plant genome research program and the plant biotic interactions program in the division of integrative organismal systems. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: EDGE CMT: Evolutionary developmental systems genetics of obligate sterility in ants

Awardee: Texas Tech University

Amount: \$1,100,000.00

Abstract: a major goal of biology is to understand the links between genomes and development and how evolution has tinkered with these mechanisms to produce the **\*\*diversity\*\*** of life. ants provide powerful study systems for exploring these and related topics because they show striking **\*\*diversity\*\*** within and between species. a defining feature of ant societies is the presence of a reproductive caste system where some individuals called queens specialize on reproduction and other individuals called workers specialize on other tasks. in most species, workers possess reduced reproductive organs and are capable of reproduction under certain circumstances (e.g., queen death), but in other species, workers completely lack reproductive organs. such obligate worker sterility has evolved at least 14 times across ants, yet little is known about the molecular mechanisms regulating the expression of this obligate sterility or whether the mechanisms are the same across each of the independent origins of sterility. the overall goal of this research is to elucidate the mechanisms underlying the expression and evolution of obligate sterility in ants and to further validate the effects of genes influencing the development of sterility in fruit flies. our research may provide novel insight into conserved genetic pathways regulating animal reproduction and reproductive health. further broader impacts of the research will be training students and researchers in approaches to study the genetic basis and evolution of development, working to improve public understanding of evolution and development, and working to increase student participation in science.

a major goal of biology is to understand the mechanisms linking genomes to phenotypes and how evolution generates and tinkers with these regulatory mechanisms to produce the **\*\*diversity\*\*** of life. one striking phenotype is the presence of an obligately sterile worker caste in social insects, which has evolved at least 14 times in ants, yet little is known about the underlying regulatory networks and whether this convergent phenotypic evolution involves convergent or parallel molecular evolution. the overall goal of this research is to use an integrative approach to elucidate the gene regulatory networks underlying the expression and evolution of obligate sterility in ants. ants provide a rare opportunity to study how infertility and sterility evolved within the context of their societies, connecting individual germline loss to colony-level gain of a

sterile worker caste. the germ-soma distinction within organisms is fundamental to multicellular life, and germline sequestration is a fundamentally important step in animal development. this research may contribute to understanding general principles and molecular pathways associated with animal development and the origin of cell types. moreover, the research may provide novel candidate genes and pathways regulating a range of complex phenotypes associated with reproduction, reproductive health, to be further studied in model organisms. further broader impacts of the grant include training students and postdoctoral researchers in approaches to study the genetic basis and evolution of development, working to improve public understanding of evolution and development, and working to increase student participation in stem fields. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: CAREER: Signal to Noise: How Complex Social Information Regulates Brain Genomics and Behavior

Awardee: University of Kentucky Research Foundation

Amount: \$1,042,815.00

Abstract: life experiences change individual behavior through complex interactions between environmental inputs and gene activity in the brain; it is unclear why certain experiences have lasting effects on behavior while other effects are easily reversed. this question is relevant to animal bio\*\*diversity\*\*, but also human health research, where one goal is to mitigate the behavioral impacts of experiences like social trauma. though dynamic brain gene activity underlies experience-induced changes in behavior, the exact mechanisms that regulate the persistence of an experience are unclear. for example, experience may chemically alter brain dna and therefore permanently change gene activity. however, a change in gene activity itself may be temporary, but lead to permanent changes in other factors that influence behavior, like brain structure. this study

uses experimental manipulations of gene regulating mechanisms to determine whether certain ones reliably predict the longevity of an experience. the subject of these studies is the honey bee (*apis mellifera*), a critical crop pollinator with a well-established relationship between social experience, brain gene activity, and aggressive behavior. teams composed of students and beekeepers will complete research objectives and organize a summit that introduces high school students to research results and academic, industry, and non-profit career opportunities in agricultural stem. in addition to filling critical knowledge gaps in the study of behavioral **\*\*diversity\*\***, this project will improve public science literacy and enhance partnerships among students and professionals inside and outside of academia. these steps contribute to an overall outcome of increased stem workforce **\*\*diversity\*\***, retention and career success.

in honey bees, adult defensive aggression and brain gene expression are persistently changed by social information accrued over the course of several days. to a degree, these phenotypes are also responsive to immediate information about threats to the beehive, enabling researchers to assess the circumstances under which persistent social experiences are updated by new information. persistent effects are correlated with changes in brain dna methylation and decreased lipid content in a peripheral endocrine tissue known to impact brain gene expression, the fat body. thus, the longevity of social experience could be a result of the gene regulatory impacts of brain dna methylation, endocrine signaling patterns, or both. researchers use intricate adult social manipulations to produce bees that display similar levels of aggression, but with different gene regulatory underpinnings (variation in brain dna methylation, fat body lipid content, or both). these bees will be used to examine which regulatory mechanisms predict the strength of response to new information, in terms of behavior, brain physiology (mitochondrial bioenergetics), and genome function (gene expression and chromatin accessibility measured using rna-seq, bisulfite-seq and atac-seq). larval bees also show persistent behavioral effects of their pre-adult environment. manipulations of larvae and measures of adult behavior will be used to determine whether the longevity mechanisms identified in adults also apply to a second life stage. this study addresses critical knowledge gaps in the relationship between brain genomics and behavioral

plasticity, including how peripheral systems and brain epigenetic mechanisms work together to regulate brain gene expression and behavior. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: DMREF: Symmetry-Guided Machine Learning for the Discovery of Topological Phononic Materials

Awardee: University of California-Santa Barbara

Amount: \$1,040,000.00

Abstract: non-technical description: fundamental understanding and control of heat conduction processes in materials are important for energy infrastructure, electronic devices, and renewable energy generation systems. this project focuses on a novel property of phonons ? vibrations of atoms that carry the heat in materials - called "topology". this property may allow new phenomena, such as heat conduction perpendicular to the temperature gradient direction and more efficient transport of heat waves on the material surfaces. to discover topological phonons, the research team will exploit a materials genome approach to search for materials hosting these special heat carriers. once candidates are identified, the research team will synthesize and characterize them, and the results will be used to refine the search algorithm. the research team plans to establish a public database storing the heat conduction properties of a large number of materials. this research will not only advance the fundamental understanding of how topology affects heat conduction in real materials, but also provide new routes to realizing unusual functionalities such as heat conductors that can be switched on and off. this project also supports educational activities to teach basic materials physics concepts to k-12 and undergraduate students through hands-on class projects and short courses. to promote **\*\*diversity\*\*** in the materials science workforce, the team also provides research opportunities to high school and undergraduate students from underrepresented

minority communities.      technical description: while the topology of electronic states has been a central theme in condensed matter physics for the past decade, topological phononic states have received much less attention. unlike their fermionic counterparts, topological states in the entire phonon spectrum can contribute to observable material properties, making topological phononic materials ideal testbeds for emerging new physics in topological bosonic systems, including phonon thermal hall effects, novel topological phonon-electron interactions and the resulting phenomena, such as unusual superconducting states. this project aims to systematically identify materials hosting intrinsic topological phonons in the thermal regime, where the topological phononic states explicitly modify intrinsic material properties, including thermal transport, electron-phonon interactions, and surface phonon modes. the research team will seek to accelerate material discovery by incorporating symmetry-guided machine learning based on euclidean neural networks. machine learning predictions will be verified using first-principles phonon simulation and topological invariance analysis. promising candidate materials will be synthesized as thin films and bulk single crystals and characterized using inelastic neutron and x-ray scattering, thermal transport, and surface-sensitive spectroscopy and scanning probe measurements. this research will advance fundamental understanding of topological bosonic systems and examine new thermal functionalities enabled by topological phonons.      this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Local-Scale Drivers and Responses of Thermospheric Weather above Antarctica

Awardee: University of Alaska Fairbanks Campus

Amount: \$1,034,406.00

Abstract: observations of the earth's upper atmosphere at the altitudes from above 100-km to a few hundred kilometers is subjected to highly variable forces as from the top (energy and momentum

transferred down from the solar wind interaction with geomagnetic field) as well as from the bottom ? from the lower atmosphere and mesosphere which generate gravity waves from the global atmospheric circulation driven mainly by the solar radiation. it is not easy to explore the upper atmosphere which lays below the satellite orbits, so only a remote technique instrumentation (such ground-based fabry-perot spectrometers, fps) is used for that kind of studies. latitudes of interests here are polar regions, specifically antarctica where two modern fpss are deployed at mcmurdo and south pole stations. this award will focus on the behavior and governing physics of the transition from the neutral fluid-like dynamics in the lower atmosphere to the plasma electrodynamics in the ionosphere and geospace domain above it. this transitional domain is frequently called the space-atmosphere interaction region (sair). knowledge of sair's properties and dynamics are important because they strongly impact many modern technological systems such as radio wave communication, navigation, and long-range radar applications. the primary goals of this research are identifying the role of waves and tides propagating upward from below and driving perturbation within the sair, and what is the role of forcing from above in driving high-latitudes thermospheric weather. the broader impact of this research is training the next generation of scientists through deep involvement of students and active support for \*\*diversity\*\* and inclusion. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Elucidating the interplay between two chromatin regulators HDA8 and ELP3 in dynamic control of primary and secondary metabolic networks

Awardee: Purdue University

Amount: \$1,002,041.00

Abstract: this project will yield knowledge on how plants coordinate metabolic networks to produce specialized metabolites that facilitate plant interactions with their environment, ranging from

attracting pollinators and seed dispersers to protecting themselves from biotic and abiotic stresses. to date, it remains largely unknown how metabolic networks are regulated to balance the needs for maintaining essential functions and producing specialized metabolites. this project will shed light on chromatin regulatory mechanisms that coordinate metabolic networks to produce volatile secondary metabolites, by testing the hypothesis that an interplay between two chromatin regulators controls the dynamic metabolic flux through primary and secondary metabolic pathways. the obtained knowledge has practical implications for both agriculture and ecology, with potential to improve plant reproductive success, plant defense and stress responses, crop nutritional value, and yield of high value phytochemicals. this project will provide multidisciplinary training for the next generation of scientists, including minorities and high school students, in stem research. preliminary studies using petunia hybrida flowers as a model system led to the hypothesis that histone deacetylase 8 (phhda8) works with the histone acetyltransferase phelp3 to regulate primary and secondary metabolic networks responsible for the biosynthesis and emission of volatile secondary compounds. to test this hypothesis, the following research objectives will be performed: (1) determining the impact of phhda8 and phelp3 on dynamics of primary and secondary metabolic networks via metabolic profiling; (2) deciphering the genome-wide targets of phhda8 and phelp3 in primary and secondary metabolic networks using functional genomics approaches; and (3) elucidating the molecular mechanisms coordinating phhda8 and phelp3 activities through biochemical approaches. this work will provide important mechanistic insights into the mode of action and interaction of histone acetylation proteins. the obtained knowledge will have a far-reaching impact on understanding chromatin level regulation underlying the chemical **diversity** found in nature and airborne communications in the plants. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Mentorship and Project-Based Learning to Support Computational Thinking and Computer Science Education Pathways for Underrepresented Students in Los Angeles

Awardee: University of California-Los Angeles

Amount: \$1,000,000.00

Abstract: educating black and latinx middle and high school students in the field of computer science with specialized skills is of high social and economic interest to the united states. computational thinking skills, such as persistence in working with difficult problems and collaborating with others to achieve a common goal, are foundational in preparing students for careers in computing and technology. this partnership between ucla and a neighboring middle and high school in south los angeles will explore how developing computational thinking skills may also enhance students' understanding of math concepts. to do this, the team will focus on supporting students of color through two critical aspects of education pathways through computer science: the delivery of knowledge by teachers and social influence near-peer mentors. this project builds upon a current partnership between the critical design and gaming schools (cdags) in south los angeles and the center for the transformation of schools (cts) at ucla that centers on effective interventions for 9th grade underrepresented students and expands the work to 300 students in 6th-12th grade. the project seeks to advance understanding of effective models for ct student development in schools that serve predominantly low-income students of color, as well as the types of educational pathways and partnerships that can remove barriers to learning and how ct development can be used as a means for promoting student learning in mathematics. the proposal investigates two critical factors in the cs preparation pathway: the delivery of knowledge by teachers and social influence near-peer mentors. the model will emphasize common instructional strategies to promote ct development and mentorship from ucla's center for excellence in engineering and \*\*diversity\*\* (ceed) an organization that will provide a pipeline of undergraduate mentors to work with teachers and student mentees at both schools. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Adaptation: Adapting Successful Practices to foster an Inclusive, Respectful, and Equitable Environment (ASPIRE2)

Awardee: University of Texas at Dallas

Amount: \$1,000,000.00

Abstract: the university of texas at dallas (ut dallas) will be adapting successful practices to foster an inclusive, respectful, and equitable environment (aspire2) to significantly and systematically transform the campus in ways that will expand and enrich the **\*\*diversity\*\*** of its faculty in stem fields and beyond. through the aspire2 project, ut dallas will adapt and implement successful activities to foster a more inclusive campus climate, recruit more women in stem fields, (including women of color and women from underrepresented minority groups), and aid in the retention of all women faculty, in stem and across campus. the goal of the project is help ut dallas, a major research university, better reflect and represent the world in terms of gender and racial **\*\*diversity\*\***. by doing so, ut dallas can better serve its community, state and country, helping solve the national crisis of the disproportionate lack of tenured-system women, especially in stem fields. the outcomes of the aspire2 project are expected to bring about structural and cultural transformation and tackle persistent problems in innovative and intersectional ways. the aspire2 activities include: climate (training for deans, department/program heads, and faculty will be conducted; a department/program head council will be formed; an advocates and allies program will be developed; a biennial climate survey will be administered; and equity dashboards for the university and individual schools will be instituted), identification and recruitment (activities include future faculty career development workshops, paying careful attention to the composition of and training for search committees, and providing faculty liaisons to search committees), and retention and advancement (strengthening the existing faculty mentoring program, creating a women in stem employee resource group, and augmenting existing workshops for faculty promotion and tenure).

this project will enhance the climate on the ut dallas campus while broadening the participation and success among women faculty, particularly women of color and women from underrepresented minority groups. building on existing efforts, ut dallas is well-poised to create a more welcoming and inclusive environment by adapting previously vetted initiatives and strengthening the relationships across campus between administrators, faculty, and staff through the aspire2 activities. increasing faculty **\*\*diversity\*\*** will fuel new research collaborations while enriching teaching, learning and the overall student experience. the nsf advance program is designed to foster gender equity through a focus on the identification and elimination of organizational barriers that impede the full participation and advancement of diverse faculty in academic institutions. organizational barriers that inhibit equity may exist in policies, processes, practices, and the organizational culture and climate. advance "adaptation" awards provide support for the adaptation and adoption of evidence-based strategies to academic, non-profit institutions of higher education as well as non-academic, non-profit organizations. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: NSF RISE: Enhancement of Research Capability and Development of Early Career Faculty at Tuskegee University

Awardee: Tuskegee University

Amount: \$1,000,000.00

Abstract: the historically black colleges and universities research infrastructure for science and engineering (hbcu-rise) activity within the centers of research excellence in science and technology (crest) program supports the development of research capability at hbcus that offer doctoral degrees in science and engineering disciplines. hbcu-rise projects have a direct connection to the long-term plans of the host department(s) and the institutional mission and plans for expanding institutional

research capacity as well as increasing the production of doctoral students in science and engineering. with support from the national science foundation, tuskegee university intends to mentor five early career stem faculty by immersing them in four interconnected activities. the proposed interventions enhance research and education in advanced materials, provide research experiences at national laboratories, foster grantsmanship and provide training in career-life balance.

the goal of the tuskegee university (tu) rise proposal is to develop, implement and disseminate a model to increase the number of junior faculty with the expertise in materials science and engineering (mse) at tu who will in turn increase the production of phds in mse. five early career stem faculty will be immersed in the following four interconnected mentored interventions designed to bolster their expertise in mse research and develop skills in the preparation of competitive proposals for research funding while adopting positive work-like balance practices: intervention 1 (research) will enhance research and educational capabilities in advanced materials; intervention 2 (research) will provide research experiences at national laboratories; intervention 3 (grantsmanship) will foster grantsmanship through mentored support in all pre and post award processes; and 4) intervention 4 (work-life balance) will provide a workshop series on career-life balance. these interventions will allow tu junior faculty to become more competitive in attracting research grants from federal agencies and foundations and increase the number of underrepresented african american doctoral students. the processes and knowledge developed through interventions 1 & 2 in advanced materials will help in product development in areas such as biomedical, agriculture and polymer science. additionally, the knowledge that will be generated by the rise model is scalable and can be replicated at other hbcus to overcome the challenges faced by their junior faculty. the broader impacts also include improved research capabilities at tu in advanced materials and the production of many minorities and women with b.sc., m.sc. and ph.d. degrees. participating students will be trained in cutting-edge research and learn communication and interpersonal skills which will enable them to become role models for other students. moreover, these graduates will help bring much-needed **\*\*diversity\*\*** to the nation's advanced technological workforce. the human and

physical scientific infrastructure established by the rise grant will contribute to tu's long-term vision of reaching the carnegie classification as a doctoral granting institution. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Amount: \$1,000,000.00

Abstract: the historically black colleges and universities research infrastructure for science and engineering (hbcu-rise) activity within the centers of research excellence in science and technology (crest) program supports the development of research capability at hbcus that offer doctoral degrees in science and engineering disciplines. hbcu-rise projects have a direct connection to the long-term plans of the host department(s) and the institutional mission and plans for expanding institutional research capacity as well as increasing the production of doctoral students in science and engineering. with support from the national science foundation, tuskegee university intends to mentor five early career stem faculty by immersing them in four interconnected activities. the proposed interventions enhance research and education in advanced materials, provide research experiences at national laboratories, foster grantsmanship and provide training in career-life balance. the goal of the tuskegee university (tu) rise proposal is to develop, implement and disseminate a model to increase the number of junior faculty with the expertise in materials science and engineering (mse) at tu who will in turn increase the production of phds in mse. five early career stem faculty will be immersed in the following four interconnected mentored interventions designed to bolster their expertise in mse research and develop skills in the preparation of competitive proposals for research funding while adopting positive work-life balance practices: intervention 1

(research) will enhance research and educational capabilities in advanced materials; intervention 2 (research) will provide research experiences at national laboratories; intervention 3 (grantsmanship) will foster grantsmanship through mentored support in all pre and post award processes; and 4) intervention 4 (work-life balance) will provide a workshop series on career-life balance. these interventions will allow tu junior faculty to become more competitive in attracting research grants from federal agencies and foundations and increase the number of underrepresented african american doctoral students. the processes and knowledge developed through interventions 1 & 2 in advanced materials will help in product development in areas such as biomedical, agriculture and polymer science. additionally, the knowledge that will be generated by the rise model is scalable and can be replicated at other hbcus to overcome the challenges faced by their junior faculty. the broader impacts also include improved research capabilities at tu in advanced materials and the production of many minorities and women with b.sc., m.sc. and ph.d. degrees. participating students will be trained in cutting-edge research and learn communication and interpersonal skills which will enable them to become role models for other students. moreover, these graduates will help bring much-needed **\*\*diversity\*\*** to the nation's advanced technological workforce. the human and physical scientific infrastructure established by the rise grant will contribute to tu?s long-term vision of reaching the carnegie classification as a doctoral granting institution. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: ADVANCE Adaptation: Project SAGES: Striving to Achieve Gender Equity in STEM

Awardee: SUNY at Albany

Amount: \$1,000,000.00

Abstract: the university at albany is a doctoral institution with a strong commitment to research excellence. it boasts a highly diverse undergraduate population and strives to excel as a diverse and

inclusive campus community; yet, women and women of color are underrepresented in the faculty ranks of stem departments. the goal of project sages is to create an environment in which women of all backgrounds and identities can thrive and develop their careers to their fullest potential. to accomplish this goal, project sages seeks to increase the number of women scientists in stem fields through proactive recruitment and unbiased hiring procedures and retain them by creating a climate and culture in which women feel supported, thrive, and advance in their careers from assistant to associate to full professor.

the aims of project sages are threefold: aim 1 seeks to increase the **\*\*diversity\*\*** of applicant pools for faculty searches in stem through a postdoctoral visitation program to identify competitive candidates for job vacancies and by education of search committees and decision makers on inclusive, unbiased search processes. to promote diverse applicant pools, search chairs will receive real-time feedback about pools to permit proactive measures if **\*\*diversity\*\*** does not meet national norms for the field. aim 2 seeks to improve the campus climate by subtly shifting departmental norms and cultures. departmental interventions will comprise awareness training for chairs, the formation of department climate committees, and ally training for men and women, all with the goal of creating a more inclusive environment. in addition, consistent and transparent policies and procedures will be implemented that meet the needs of a diverse faculty. aim 3 seeks to support women's research success. a networking program for women faculty and women of color and a pilot funding program will allow women in stem to build collaborative research teams. additional support is provided with a novel external sponsor program in which female assistant professors are paired with a prominent expert from another university who will provide ongoing guidance on best strategies for networking, funding, publishing, and achieving tenure. through these interventions, project sages aims to bring about sustained institutional transformation at the university at albany with the goal of achieving inclusive excellence in stem that better reflects the university's highly diverse student body. the interventions will lead to a more nurturing and family-friendly environment for women scientists of diverse identities and maximize their success through comprehensive professional support structures and an equitable tenure and

promotion process. outcomes from project sages will be disseminated through multiple outlets including a website. the nsf advance program is designed to foster gender equity through a focus on the identification and elimination of organizational barriers that impede the full participation and advancement of diverse faculty in academic institutions. organizational barriers that inhibit equity may exist in policies, processes, practices, and the organizational culture and climate. advance "adaptation" awards provide support for the adaptation and adoption of evidence-based strategies to academic, non-profit institutions of higher education as well as non-academic, non-profit organizations. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Applying Student Knowledge for Success in Cybersecurity and Data Science

Awardee: Fairleigh Dickinson University

Amount: \$999,987.00

Abstract: this project will contribute to the national need for well-educated scientists, mathematicians, engineers, and technicians by supporting the retention and graduation of high-achieving, low-income students with demonstrated financial need at kean university, the new jersey institute of technology, fairleigh dickinson university, brookdale community college, and union county college. in particular, it responds to areas of national need in cybersecurity and data science by increasing the number of students graduating in computer science (cs) and information technology (it). moreover, the project will build regional workforce strength and contribute to the knowledge base on the role of student competence and belonging in ensuring persistence to degree attainment. over its five-year duration, a total of 256 students will benefit, receiving scholarships to complete cs or it degrees. project components include scholarship support for students, undergraduate research and/or professional experience opportunities prior to graduation, and generation of new knowledge through research on economic realities for students and impact on

career trajectories in cybersecurity and data science. students in this program will be prepared to enter the scientific workforce or graduate school as competent, highly trained individuals with a background in teamwork and research. furthermore, they will contribute to increased professional **\*\*diversity\*\*** in the fields of cs and it, and serve as role models to members of their communities.

the students recruited for this program will participate in workshops, take advantage of cohort experiences, and interact closely with faculty who will provide i) academic advising, ii) guidance for navigating higher education and postgraduate opportunities, and iii) supervision of teamwork, research, and working professional experiences. through undergraduate research opportunities and experiences from participation in faculty research programs and/or existing summer research and internship programs, these individual and cohort experiences will provide a basis for overall intellectual growth and promote increased student confidence, retention, and timely degree completion. these academic outcomes are in turn expected to allow students to successfully navigate common attrition points including financial hardship and professional identity development for post-graduate employment and continued education. the project's academic environment includes student-faculty advising and undergraduate research activities, using the affinity research group (arg) model and peer-mentoring. the use of teamwork, collaboration and student-motivated question and answer sessions will positively support research in the field of computer science and information technology regarding educational impact and retention, particularly for minorities, female, and first-generation students. this project is funded by nsf's scholarships in science, technology, engineering, and mathematics program, which seeks to increase the number of low-income academically talented students with demonstrated financial need who earn degrees in stem fields. it also aims to improve the education of future stem workers, and to generate knowledge about academic success, retention, transfer, graduation, and academic/career pathways of low-income students. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Closing STEM Student Academic Performance Equity Gaps Through Student Research Exposure and Faculty Professional Development in Pedagogy and Curricular Innovation

Awardee: Riverside Community College District/Riverside City College

Amount: \$999,968.00

Abstract: with support from the improving undergraduate stem education: hispanic-serving institutions (hsi program), this track 2 implementation and evaluation project will implement evidence-based faculty development leading to an institutional culture supportive of **\*\*diversity\*\***, equity, and inclusion within stem disciplines at a minority serving community college. further, it will demonstrate the combined impact of such pedagogical and curricular practices with sustained, multi-faceted student supports, and enhanced exposure to undergraduate research experiences for building stem identity, leading to improved student academic performance and successful transfer to baccalaureate stem degree programs. annually, rcc serves more than 30,000 students. students from traditionally underrepresented ethnic backgrounds represent 73% of students enrolled at rcc, of which hispanic students are the majority group (63%). for the students of rcc, education, especially stem education, offers the promise of improving their social mobility and quality of life. however, these disciplines are among the most rigorous, and have high course failure and attrition rates. there are notable equity performance gaps in core stem course performance, persistence within stem, and transfer to four-year universities for hispanic, african american, and other underrepresented groups in higher education. we seek to change that through sustainable improvement in teaching and learning. to accomplish this goal, we are partnering with california state university san bernardino (csusb) to replicate work they have done with faculty development around inclusive and responsive stem pedagogy, and to expand targeted student support, mentorship and exposure to student research opportunities. two complementary sets of activity will be implemented: (1) peer-led faculty professional development focused on pedagogical and

curricular improvements in stem; (2) expansion of student experiential learning and research within and across stem disciplines, and through exposure to summer research experiences at a transfer destination university. those activities will result in (1) increased stem faculty knowledge, skills, and utilization of culturally sensitive, inclusive, and active learning pedagogy; (2) increased stem student retention, term-to-term persistence, course success, and transfer rate, and closing of student equity gaps; (3) contributions to the knowledge-base about **diversity**, equity and inclusion (dei) in stem.

the project will create a stem faculty learning community (flc) to develop and implement equity-minded, evidence-based practices proven effective for supporting hispanic and other underrepresented students to succeed in postsecondary stem education. research will contribute to the knowledge on stem education within minority serving institutions by employing a mixed-methods approach to holistically assess the project's implementation and outcomes at multiple levels. the project will measure changes in flc participants' awareness and implementation of high-impact practices and knowledge of dei issues in stem, and changes in students' stem-related identity, belonging, and career plans, as well as their academic performance and trajectory. the project results will be informed by and contribute to the literature on underrepresented minority student persistence and success in stem disciplines, as well as stem faculty professional development focused on high-impact teaching practices. results of this work will be disseminated to multiple audiences via disciplinary conferences, and presentations at conferences specific to community colleges and hispanic serving institutions. the hsi program aims to enhance undergraduate stem education, broaden participation in stem, and build capacity at hsis. achieving these aims, given the diverse nature and context of the hsis, requires innovative approaches that incentivize institutional and community transformation and promote fundamental research (i) on engaged student learning, (ii) about what it takes to diversify and increase participation in stem effectively, and (iii) that improves our understanding of how to build institutional capacity at hsis. projects supported by the hsi program will also draw from these approaches to generate new knowledge on how to achieve these aims. this award reflects nsf's statutory mission and has been deemed worthy of support

through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Adaptation: Empower through Inclusivity: Developing Pathways to Success

Awardee: South Dakota School of Mines and Technology

Amount: \$999,963.00

Abstract: an nsf advance adaptation award will allow the south dakota school of mines and technology (sdm) to initiate new programs and improve upon existing data collection and personnel policy to enhance gender, racial, and ethnic **\*\*diversity\*\***. sdm is a phd granting engineering science and technology university that is geographically isolated, surrounded by counties in the region considered frontier and remote (far) areas having populations of less than 7 people per square mile. its size (2700 students, 145 faculty), location, and stem focus provide challenges with respect to retention of a diverse faculty. our intent for this project will be to empower sdm faculty and research staff by shifting from a culture of attrition to a culture of development and engaging the majority populations of faculty at sdm to increase awareness of implicit biases, promote pathways to success for all faculty, and improve campus culture and climate. through careful curation and adaptation of successful advance initiatives, the project aims to enable a change in institutional culture. the project design is rooted in an understanding of the current climate and needs of the sdm faculty, including instructors and research professionals. the merit of the project is that it engages top-down support for programs that will have a marked impact on campus climate allowing for a transition from a culture of attrition to a culture of development. to improve retention of underrepresented groups, the project intends to include adaptation of three proven programs: advocates and allies (ndsu), facilitated mentoring circles (murray state), and mutual mentoring (umass). these programs are structured to include feedback to improve policy, involve expert advisors and evaluators, and are rooted in an enhanced plan for data collection and analysis. this project aims to directly address the

need to improve the participation of women in stem fields by providing programs to increase retention and career advancement at a science and engineering specialty school in an epscor state that serves a far region. planned activities will not only benefit women tenure-track faculty but will be made available to individuals in other career paths (instructional and research staff), to all genders, and to all ethnicities/races represented on campus. these efforts also will lead to improved educational opportunities for students to learn with a diverse faculty with members fully engaged in campus culture. best practices from sdm efforts will be made available to other institutions in the state, including the other five institutions in the board of regents system, three tribal colleges/universities, and two private universities. the nsf advance program is designed to foster gender equity through a focus on the identification and elimination of organizational barriers that impede the full participation and advancement of diverse faculty in academic institutions. organizational barriers that inhibit equity may exist in policies, processes, practices, and the organizational culture and climate. advance "adaptation" awards provide support for the adaptation and adoption of evidence-based strategies to academic, non-profit institutions of higher education as well as non-academic, non-profit organizations. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: RAISE: Spring & Wings: Resonance in insect and engineered flight with synchronous and stretch-activated actuation

Awardee: Georgia Tech Research Corporation

Amount: \$999,844.00

Abstract: this research advanced by interdisciplinary science and engineering (raise) project will develop a dynamical model to enhance understanding of insect flight as an integrated system and apply this information to robotic design. flight at the size of insects is very energetically challenging.

nonetheless, the evolution of flight spurred much of the evolutionary **\*\*diversity\*\*** of insects we see today. insects fly long distances, maneuver in crowded and gusty environments, and overcome the energetic limitations of flapping wing flight in ways that cannot yet be matched in human-engineered systems. insects couple springy exoskeletons to their wings to help store and return energy on every flap; however, to maximize energy return, insects would have to beat their wings at a steady rate. this project will explore how insects couple springs and wings together to manage energy requirements and flight control under a range of conditions. this project will also explore how the two distinct types of muscle contraction that insects use to power flight could both be achieved with the same underlying mechanics and muscle properties, enabling a mathematical framework for understanding how insects achieve such different types of flight. the project will use robophysical models with springy exoskeletons coupled to wings and insect-scale flapping robots to establish a general "spring-wing" framework. research at both collaborating institutions will include an immersive, vertically integrated undergraduate research program. student teams will receive mentorship and on-site research experience during the school year and will travel to their exchange location for interdisciplinary summer research. at least two graduate students and a post-doctoral fellow will also receive cross-disciplinary training. insect-scale flapping-wing flight demands both high-power actuation and low-latency control. to mitigate flight power requirements, most insects actuate their wings indirectly via muscles that deform a stiff, elastic exoskeleton. coupling elastic elements to the wings allows insects potentially to operate as a resonant system, which would reduce power costs but also would introduce control constraints, such as limiting wingbeat frequency modulation. to power flapping flight, insects evolved two distinct actuation strategies: synchronous flight, with time-periodic forcing of antagonistic muscles paced by the nervous system, and asynchronous flight, in which muscles set up self-excited oscillations due to strain-dependent activation. the project will establish an analytic framework for spring-wing systems, test if insects operate at their hypothesized resonant frequencies, and develop a dynamically scaled robophysical spring-wing flapper to explore how a single non-dimensional parameter, the weis-fogh number,

influences elastic energy storage and aerodynamic force control. the two muscle actuation strategies will then be combined, testing if synchronous flying insects that have evolved from asynchronous insects retain the necessary physiological signatures of self-excited (asynchronous) oscillations. a single dynamic system that can transition from the two regimes of stable flapping will be tested in the robophysical system and in an at-scale, bio-inspired flapping wing robot. finally, the tradeoffs of operating at or away from resonance in spring-wing systems will be investigated. the project bridges the biological and physical sciences, will expand understanding of physiological and biomechanical principles and trade-offs involved in flight, and should transform the current understanding of insect flight, with applications to robotics. undergraduate and graduate students and a post-doctoral fellow will participate in mentored, interdisciplinary research teams, and will present research results at national scientific meetings. research results will also be disseminated through a bio-inspired design workshop. this award is co-funded by the dynamics, control and systems diagnostics program in the division of civil, mechanical and manufacturing innovation, directorate for engineering, and the physiological mechanisms and biomechanics program in the division of integrative organismal systems, directorate for biological sciences. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: ADVANCE Adaptation: CSU STEPS for Gender Equity: Advancing Structures through Evidence-based Practices for Gender Equity

Awardee: Colorado State University

Amount: \$999,312.00

Abstract: colorado state university will tackle the significant nation-wide problem of inequity among faculty members in science, technology, math and engineering (stem) disciplines. specifically, this project aims to improve equity in recruitment, retention and promotion, with a focus on gender equity

that recognizes the other types of cultural, ethnic, physical, and economic backgrounds people have. the work thus targets improved **\*\*diversity\*\*** in stem disciplines. this problem is important because more diverse workforces are more effective at solving problems, and in a more just society, university faculty composition would reflect availability of doctoral graduates without bias. this problem has not already been solved because inequities are complex and embedded into the history of us society and academia. it is not intractable, however, and through carefully executing projects, colorado state aims to improve equity across the stem faculty. to address inequities, the project team aims to adapt a number of evidence-based best practices to particular situations at colorado state. the project targets four major changes. 1) a revised approach to recruiting new faculty. 2) improved unit climates through training allies to intervene when they notice inequities. 3) improved performance review processes with training and support for review committees. 4) enhanced leadership through education in equity who are both empowered to and accountable for making change. the expected outcomes of the project activities are improved climate and culture for all, and improved recruitment and retention leading to greater equity and **\*\*diversity\*\*** in stem units across campus.

the overarching goal of advance adaptation: csu steps for gender equity: advancing structures through evidence-based practices for gender equity is to transform university and unit structures and culture to improve climate and gender equity on stem faculties, with an intersectional focus on women with identities that historically have been marginalized. the specific aims are as follows: 1) enhance recruitment, 2) improve retention through training promotion and tenure committees, creating a cadre of equity-minded allies, and collecting qualitative data to understand departures and retentions, and 3) support and train unit leaders in equity efforts. thus, the scope of the project encompasses equity across all phases of faculty careers and on into leadership. the research methods include quantitative and qualitative approaches to evaluate success in providing participants with new skills, in improving department climate, and in retention outcomes. expected results include an increase in equitable recruitment and retention, improved climate, and a better understanding of the specific barriers faculty face. the project aims to

contribute to research literature in organizational change and equity. outcomes and findings will be disseminated at conferences, in academic publications, and in articles and talks for broad audiences. the nsf advance program is designed to foster gender equity through a focus on the identification and elimination of organizational barriers that impede the full participation and advancement of diverse faculty in academic institutions. organizational barriers that inhibit equity may exist in policies, processes, practices, and the organizational culture and climate. advance "adaptation" awards provide support for the adaptation and adoption of evidence-based strategies to academic, non-profit institution of higher education as well as non-academic, non-profit organizations. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Engaging Teachers and Neurodiverse Middle School Students in Tangible and Creative Computational Thinking Activities

Awardee: Arizona State University

Amount: \$998,712.00

Abstract: students with disabilities, particularly those with autism, experience unequal outcomes in stem education and employment. despite frequently reported strengths and interests in stem disciplines, individuals with autism often do not receive the support?those related to communication, transitions, and flexibility?needed to succeed. in working with teachers, parents, and employers, this project will create pathways to position students with autism spectrum disorder for success in school and also the larger community. researchers from arizona state university and the neuro\*\*diversity\*\* educational research center (nerc) and practitioners at science prep academy (spa) and temple grandin school will collaborate on the development of learning activities and workshops that engage middle-school aged children, community members, and employers in activities that integrate music, technology, and computational thinking. for the employers and community members, participation

can lead to increased respect for neurodiverse children and job applicants and changes in stem field's hiring practices and workplace accommodations. teachers engaged in the process of co-designing the learning experience and additional teachers engaged in workshops will be able to learn new approaches for supporting learning. finally, this project aims to build pathways of support and facilitation for neurodiverse individuals that increase employment potential of students with autism in a more inclusive economy, where neuro\*\*diversity\*\* is a baseline rather than an exception.

the project is based on embodied learning and cooperative learning approaches that inform the team's development of telematic embodied learning (tel) activities: activities that engage participants in using movement and their bodies to understand concepts, and can be conducted in hybrid or remote teaching situations when students and teachers are in different locations. the project's iterative co-design process and practitioner model are designed to provide data on the kinds of support and training teachers would need to equip neurodiverse students with computer science concepts. the project's researchers will use a convergent mixed methods design to investigate the experiences of approximately 25 middle-school-aged children, 24 teachers, 15 parents, and 10 future employers through a combination of surveys, observations, interviews, and focus groups. the research aims to investigate how telematic embodied learning approaches enriched with computational media foster computational thinking; how teachers who participate in the tel workshops modify and diversify their teaching practices; how tel approaches can be adapted in other schools; and how tel approaches augment the learning of ct in computer science with developing socio-emotional skills impact future employment for neurodiverse children with autism. this project is funded through the cs for all: research and rpps program. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: DISES: Resilient Socio-Environmental Systems: Indigenous Territories in the Face of Change

Awardee: University of Florida

Amount: \$998,682.00

Abstract: indigenous peoples are capable of conserving their natural environments in the face of significant development pressures. nevertheless, little is known about the conservation efficacy of their social-environmental practices. the study addresses this issue through a partnership with an indigenous nation to ascertain how they have been able to achieve cultural and bio\*\*diversity\*\* conservation, even with threats arising from resource extraction and large-scale infrastructure projects. thus, the study provides information critical to tropical forest conservation. research results on climate change mitigation strategies will be broadly disseminated among indigenous communities. since indigenous peoples manage 40 percent of protected areas globally, the potential conservation impact is great. the study builds local capacity by training eight indigenous research technicians, and it empowers indigenous communities by facilitating the design of territorial management plans that foster long-term indigenous resilience in the face of development pressures. in addition, the study supports a post-doctoral researcher and promotes \*\*diversity\*\* by training three graduate students from historically under-represented populations. this study enhances cross-cultural learning by partnering undergraduate students through online "virtual exchanges" and summer field courses. a robust science communication strategy ensures that study results will inform both academics and the general public about how indigenous social-environmental practices shape contemporary conservation strategies. this study focuses on the indigenous territory (it), an integrated socio-environmental system capable of maintaining sustainable interactions between a human population and the physical environment. its can be resilient to external threats by virtue of biocultural heritage: the language, knowledge, and practices indigenous peoples use to sustain the ecological integrity of their homeland environments. the study problem resides in our incomplete knowledge about how such resilience functions, and the goal is to fill this gap. specifically, we seek insight into the responses of its to development pressures that spark encroachments on indigenous lands but also make available the goods, services, and jobs of a market economy. at what point

does it resilience attenuate, precipitating the loss of biocultural heritage and ecosystem degradation? how do its sustain system integration as development pressures mount? the study team will address such questions with its indigenous partners, which is subject to threats from resource extraction and infrastructure development that are similar to those impacting the entire region. the study integrates ecology, socio-environmental modeling, human geography, and spatial sciences. it will collect data via ecological assays, scientific surveys, and key informant interviews. analytical techniques include both quantitative and qualitative methods. the study contributes to systems theory by conceptualizing the it as an integrated socio-environmental system, and it enhances an understanding of it resilience. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Advancing Research and Practice in Culturally-Relevant Computing in Upper Elementary Education

Awardee: University of Hawaii

Amount: \$996,552.00

Abstract: this project is motivated by the need to prepare elementary teachers to effectively integrate computer science (cs) education into their teaching. to address this need, this project will provide professional development focused on culturally-relevant computing. culturally-relevant computing values explicit connections between students' home cultures and the concepts and practices of cs. research has shown that culturally-relevant pedagogies help students from marginalized communities succeed in a variety of fields including stem-related areas. accordingly, the project's basis is that a sustained culturally-relevant computing professional development program will be an effective way to prepare educators to reliably produce valued cs and culture-based outcomes. the work will be done by a partnership between faculty and staff at the university of hawaii at manoa

(uhm) and the hawai'i state department of education (hideoe). the project will directly address concerns about the need to prepare teachers to integrate cs into their teaching while simultaneously promoting hawai'i's unique place, history, culture, and language. the project's practical and theoretical outputs regarding culturally-relevant computing and its pedagogical implications will be applicable to other cultures and contexts interested in equity and **\*\*diversity\*\***. with the goal of better understanding the role of culturally-relevant computing in supporting cs education, this research-practitioner partnership will provide professional development to upper elementary (grades 4 - 6) educators (n = 230) in hawai'i. specifically, the project pursues practice and research objectives aligned with calls to broaden participation in cs, better understand pedagogical factors supporting effective cs education, and examine how cs education can promote cs and culture-based education outcomes. the practice objectives of the project include: 1) developing culturally-relevant computing modules, 2) implementing a professional development program about culturally-relevant computing, and 3) forming a professional learning community about culturally-relevant computing. the project's research objectives will advance the field's theoretical and practical understanding of how culturally-relevant computing impacts educators' knowledge and beliefs about (a) the subject of cs, (b) their ability to teach cs, and (c) the relationship between cs and culture-based outcomes. methodologically, the project will follow a design-based research process coupled with an explanatory sequential mixed-methods design. taken together, this project will help researchers, practitioners, and policy-makers, better understand how culturally-relevant (sustaining) pedagogy can be leveraged to increase **\*\*diversity\*\***, equity and inclusion in stem-related fields such as cs. this project is funded through the cs for all: research and rpps program this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

## Mentored K Awardees Transition to Research Independence: Explicating a Matthew Mechanism

Awardee: HEALTHPARTNERS Institute

Amount: \$995,110.00

Abstract: despite efforts at diversification, an outsized proportion of prestigious nih r01 awards go to a circumscribed group of individuals and institutions. how and why does this happen? the matthew effect, whereby success begets success, is thought to be responsible: applicants with even small advantage at the outset may have their advantage multiplied many times over following initial success. evidence is consistent with the presence of a matthew effect in r01 funding, yet no study has illuminated the specific nature of the advantage, nor detailed the means by which advantage is multiplied and accumulated. this project will answer questions about which aspects of social capital and scholarly achievement contribute most to r01 success, and whether gender or timing of scholarly events contribute, by examining the individual career trajectories of awardees of nih mentored career development awards (mk awards). project results will help design effective interventions to avert unintended funding disparities, while maintaining a rigorous peer review system. this will be the first empirical test of a matthew mechanism during transition to research independence and the first to leverage heterogeneous scholarly graphs (hsgs). the first aim is to capture complex relationships between each mk awardee, their scholarly achievement and social capital, and r01 success during their quest for research independence. existing bibliographic and nih award data will be combined in the construction of a ?global? hsg database - relating all mk awardees to their associated scholarly objects. the result will be a comprehensive graph structured database in which nodes represent all mk awardees and their associated scholarly objects (e.g., published articles, journals, primary academic institution, coauthors, coauthor?s scholarly objects), and edges represent relationships of various types (e.g., author of, cited by, affiliation, research topics). relationship context will be captured for all scholarly objects in the hsg through global, local, and hyper-local graphical feature extraction to comprehensively characterize mk awardees? scholarly profiles. second, survival models will be developed to predict r01 success for mk awardees

from latent and observed variables of scholarly achievement and social capital, and global, local, and hyper-local hsg features. the study offers a novel approach to studying complex social processes that marries social capital theory with heterogeneous scholarly graphs and network science methods. this study will go beyond previous studies in providing a multidimensional characterization of scholarly social capital (beyond coauthorship and citation) and will examine differential social capital accumulation as a mediator in mk to r01 transition. empirically-grounded predictive models will be designed to probe existing theory and yield insights on social capital's role in r01 funding success. this study will yield actionable knowledge to inform strategies aimed at improving efficiency awards and increasing the **\*\*diversity\*\*** of the awardee pool. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: PlantSynBio: Identification and Design of Transcriptional Activation Domains Across Plant Species

Awardee: University of California-Berkeley

Amount: \$993,862.00

Abstract: every plant begins life as a seed with one cell and one genome. in order for a plant to grow, the cells must divide and turn into different kinds of cells by turning on different genes. leaf cells turn on leaf genes; root cells turn on root genes. this process of turning genes on and off requires specialized proteins called transcription factors. transcription factors also allow plants to turn genes on or off to respond to stresses like drought or pests and pathogens. transcription factors turn genes on using specialized regions called "activation domains." the first part of this project will use technologies we developed to identify activation domains on all the transcription factors of one widely studied plant species, arabidopsis. the data we collect will power our computational models for predicting activation domains in other plants. the final portion of this project will build synthetic

transcription factors that can be used to engineer gene regulation in other plants. this research will create useful and powerful tools for plant biologists and plant breeders. this collaboration between three research teams creates a unique interdisciplinary training environment for undergraduates, graduate students, and postdoctoral research fellows. our team is committed to building a supportive environment that fosters equity, **\*\*diversity\*\*** and inclusion. the three pi's come from backgrounds that have been traditionally excluded from science. two of the pi's are building on the success of their nsf career awards.

in plants, transcription factors control gene regulatory programs for development, growth and stress responses. transcription factors have two functions: 1) to bind dna sequences in the genome directly with a dna binding domain (dbd) or through a partner dbd-containing protein and 2) to recruit transcriptional machinery. dbds have been well characterized and can be predicted directly from amino acid sequence. in contrast, the regions of transcription factors that bind coactivator complexes, activation domains, remain poorly characterized and cannot be predicted from amino acid sequence. for example, in arabidopsis, there are 1,717 transcription factors, but only 8 known activation domains. as a consequence, when a new genome is sequenced, models for predicting dbds can identify putative transcription factors, but there are no analogous models for predicting if these transcription factors are activators or repressors. this project will use high throughput screening methods to identify activation domains on all arabidopsis transcription factors. these data will train deep learning neural networks to predict activation domains from amino acid sequence and predict activation domains in other diverse plant species. the final portion of this project will create and validate synthetic transcription factors for engineering gene regulation in plants. these tools will expand the synthetic biology toolbox for targeted hypothesis testing of metabolic processes, engineering regulatory networks, advancing agriculture and contributing to solutions that could address environmental problems.

this award was co-funded by the plant genome research program in the division of integrative organismal systems and the systems and synthetic biology cluster in the division of molecular and cellular biosciences. this award reflects nsf's statutory mission and has been deemed worthy of support

through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Understanding When Diversity, Equity and Inclusion (DEI) Work "Counts" in Faculty Evaluation

Awardee: University of Maryland, College Park

Amount: \$987,764.00

Abstract: this study aims to increase **diversity** in stem academic workplaces by testing ?nudge? interventions to help **diversity**, equity, and inclusion (dei) work matter in promotion and tenure decision-making. nudges refer to deliberate changes to the decision-making context aimed at guiding people toward a particular behavior, which in this case is valuing dei work. many institutions

have tried to reform the tenure process to reward dei work, but there is little concrete evidence that any of these initiatives have shaped tenure decisions. despite widespread use in organizations and education, nudge science has rarely been applied to faculty evaluation decisions. the study will use an experimental vignette methodology (evm) in which faculty participants will make an explicit decision about a fictional applicant. faculty participants will be recruited from biology (specifically ecology and evolutionary biology) and engineering. knowledge from the project's findings will provide useful information to university leaders seeking to reform promotion and tenure to value dei work. many faculty members, including a disproportionate number of black, brown, and women faculty, engage in dei work, but consistently report that when it comes to tenure and promotion, they are not sure whether and how their dei work counted in decisions made. this work will examine whether three different "nudge" interventions (a) providing an equity charge encouraging participants to value dei work, (b) having the tenure candidate emphasize their dei efforts in separated sections of their cv and personal statement, and (c) having participants use a rubric in which dei is one of the criteria listed, are more influential than the others in shaping tenure decisions. an experimental vignette methodology (evm) will be used in which faculty participants will make an explicit decision about a fictional applicant. faculty participants will be recruited from biology (specifically ecology and evolutionary biology) and engineering. participants will be randomly assigned a dossier that includes the evaluation criteria, a curriculum vitae, and a personal statement. the main outcome variable is the recommendation from the participant regarding faculty tenure. this study is the first to use an experimental design to test faculty weighting of dei in tenure decisions in a stem field. this project will advance knowledge about which kinds of nudges are more likely to work within faculty evaluation settings, and whether interventions have a different impact depending on the perceived identities of the candidates. this project is funded by the ehr core research (ecr) program, which supports work that advances fundamental research on stem learning and learning environments, broadening participation in stem, and stem workforce development. this award reflects nsf's statutory mission and has been deemed worthy of support through

evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Preparing Leaders and Nurturing Tomorrows Scientists: Botany and Beyond (PLANTS III)

Awardee: Botanical Society of America

Amount: \$986,448.00

Abstract: the plants iii program will establish a series of annual workshops and activities to foster a mentoring network and community of interactions among faculty, and students, researchers, and career professionals in botany and allied disciplines with the goal of broadening participation in those disciplines. the botanical society of america (bsa) will lead this effort in support of a diverse and inclusive botanical community. by addressing plant awareness and cultivating a diverse and inclusive community of scientists, these activities can accelerate discovery, research and applied botanical sciences. these activites will engage the botanical community and professional botanical societies (e.g., bsa, the american society of plant taxonomists, the society of herbarium curators) in a collaborative effort to engage a diverse community of undergraduates, early career professionals, and faculty to affect a more inclusive scientific community. the program will provide financial

support for underrepresented students to engage with botany at multiple levels; provide several access points for students and faculty that have been historically excluded, to engage with the botanical sciences; and create a program and series of inclusive and accessible experiences that provide sustained personal and social connections supporting a diverse, inclusive and equitable botanical community. in addition, professional development workshops will provide faculty with evidence-based best practices of botanical science education, training for identifying barriers to equity and inclusion in a science classroom, and methods for engaging a **\*\*diversity\*\*** of students in the study of botanical science. all of these activities are critical to creating a diverse and inclusive 21st century workforce that will be charged with finding creative solutions to global challenges. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Evolution and genetic basis of locomotor activity patterns among Lake Malawi cichlids:  
Exploring a novel mechanism of habitat partitioning

Awardee: University of Massachusetts Amherst

Amount: \$985,559.00

Abstract: this project investigates a new hypothesis to explain how a high **\*\*diversity\*\*** of similar species can coexist in the same environment, that species partition their habitat temporally via divergence in the circadian timing of activity, day vs night. animals exhibit a range of activity levels and patterns over the course of a day, but how these behaviors are regulated at the genetic level remains poorly understood. further, closely related species can differ markedly in both levels and patterns of activity, but how variation in these behaviors may facilitate the co-existence of species within a single environment is largely unknown. this project addresses these two knowledge gaps, using cichlid fishes from lake malawi, africa. this cichlid system exhibits unparalleled **\*\*diversity\*\***, with well over 500 species evolving within the last ~1-2 million years. moreover, malawi cichlids

co-exist in extremely high diversities, with certain localities supporting over 40 species. how this occurs has long fascinated biologists, with most studies focusing on how species partition habitat spatially, for example across different depths. this research has the potential to provide novel insights into how bio\*\*diversity\*\* is maintained in the lake malawi cichlid system, and other groups characterized by high levels of bio\*\*diversity\*\*, with implications for conservation strategies. more broadly, this project will provide a better understanding of circadian biology, which may provide insights into the linkage between disrupted circadian rhythms in humans and disorders of the brain. building on past activities, the investigators will deliver summer workshops on evolution to underserved and underrepresented middle school students through partnerships with existing programs in massachusetts. they will recruit underrepresented high school and undergraduate students into their labs for supervised research. in addition, they will develop and deliver course-based undergraduate research experience laboratories for undergraduates at both institutions to expand access to research.

the circadian timing of activity is critical for organismal fitness, and species across the animal kingdom exhibit \*\*diversity\*\* in the timing of activity that ranges from strongly diurnal to strongly nocturnal. while the neural and molecular basis through which animals maintain a 24-hour circadian clock is well-studied, much less is known about how the timing of activity evolves. identifying the ecological and genetic factors associated with variation in activity patterns would therefore address a critical gap in our knowledge. this project will investigate these open questions by applying high-throughput behavioral analyses in lake malawi cichlid fishes ? an iconic and powerful model system for ecology and evolutionary research. malawi cichlids exhibit unparalleled \*\*diversity\*\* in an array of phenotypes, including behavioral traits. preliminary data associated with this proposal documented a surprisingly high magnitude of variation in locomotor activity patterns among species, offering a unique opportunity to investigate its evolution and genetic basis. to this end, the investigators will undertake experiments to examine the evolution of activity patterns in an explicit phylogenetic context, assess the degree to which these patterns are modulated by environmental factors including social interactions and food availability, and to

characterize the genetic/genomic architecture of locomotor activity. while each experiment will be informative on its own, the combined results will provide key insights into the evolutionary potential of circadian regulation of activity, significantly advancing the field, and establishing a robust foundation for future research. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: GRate ? Integrating data and modeling to quantify rates of Greenland Ice Sheet change, Holocene to future

Awardee: University of Washington

Amount: \$983,607.00

Abstract: the greenland ice sheet has experienced devastating melt in recent years. recent scientific reports highlight how vulnerable the greenland ice sheet is to arctic climate change and draw a dire picture of the impact of sea-level rise. in order to equip society with the best forecasts of sea level rise for planning, scientists need to improve the ability to simulate ? or model ? the response of ice sheets to climate change. for this project, scientists from different branches of ice-sheet research will work together to improve ice sheet modelling. the researchers will leverage recent scientific advances to model the entire greenland ice sheet in order to investigate long-term ice-sheet sensitivity to changes taking places in the ocean and atmosphere. the research group is committed to creating an inclusive environment where all team members can learn and excel. the team contains **\*\*diversity\*\*** in ethnicity, gender and rank, and will train six early career scholars, recruiting specifically from groups underrepresented in the geosciences, which is among the least diverse stem fields in the u.s. results will be made publicly available and will facilitate a broad range of future research about the arctic system, including ice sheet modeling, model spin-up, paleoclimate reconstruction/synthesis and glacier history. to elevate the capacity of outreach and education programs developed during their first project, the team will build on their ?scientists are superheroes? outreach program and leverage other, existing outreach frameworks, including making connections with greenlandic communities and with high school student intern programs at their universities linked to the young women?s leadership school (bronx, ny) and the spring valley (ny) branch of the naacp, coordinated by our dedicated project educator and outreach specialist.

reducing uncertainties in ice-sheet model predictions is crucial in society's handling of the sea level crisis. uncertainties related to ice-sheet instability arise from limited observations, inadequate model representation of ice-sheet processes, and limited understanding of the complex interactions between the atmosphere, ocean, and ice sheets. how atmospheric and oceanic forcing vary through time, and at what timescales each are capable of forcing rapid change, are critical for predicting future ice mass loss, but scientists have been observing ice sheet change for only a short period of time (decades). the pis propose to scrutinize greenland ice sheet change spanning from the beginning of the holocene (12,000 years ago) to 2100 ce, making it possible to evaluate the varying roles of atmospheric and ocean forcing on decadal-to-centennial timescales relevant for the future greenland ice sheet evolution. the pis will utilize their established multi-disciplinary collaboration to combine ice sheet modelling, climate forcing and reconstructions of past ice-sheet change. this will position the team to make predictions of future ice sheet change that are grounded in greenland ice sheet behavior during past climate swings that occurred prior to our brief window of modern observation. the work will lead to lasting products to serve the community's collective effort to better understand ice sheet change: 1) a state-of-the-art ice-sheet model optimized for simulations over long timescales, 2) a holocene-through-modern set of atmospheric and ocean state estimates optimized for forcing an ice-sheet model, and 3) a database of past-ice sheet configurations and paleoclimate records formatted for model-data comparison. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: An Evidence-Based Approach Towards Technology Workforce Expansion by Increasing Female Participation in STEM Entrepreneurship

Awardee: University of Wisconsin-Madison

Amount: \$983,486.00

Abstract: this is a collaborative project, with the university of wisconsin-madison as the lead institution and the university of maryland as the partnering institution, to explore the entrepreneurial proclivity of undergraduate women majoring in stem fields. the researchers propose a multi-method approach led by an interdisciplinary team to (1) identify factors that influence entrepreneurial proclivity and (2) develop and test interventions related to closing gender disparities in stem entrepreneurship. the research includes the analysis of a comprehensive administrative database to identify mechanisms for potential interventions and field experiments to achieve greater gender parity in entrepreneurial career choices for stem students. results of the field experiments will be integrated with the database to produce outcome measures. the project will produce empirical evidence to increase the understanding of student entrepreneurship and inform interventions that improve entrepreneurship participation for women in stem. the researchers will frame the research design and methods using the individual-opportunity nexus theory that knowledge is a precursor to entrepreneurship. there are four hypotheses: (1) greater entrepreneurial proclivity will be found in women in stem fields with higher curriculum **\*\*diversity\*\***, who have taken at least one business class, who are enrolled in stem courses with students with higher **\*\*diversity\*\*** in their courses, and who are enrolled in stem courses with students who have taken one or more business classes. (2) women stem students demonstrate higher entrepreneurial proclivity when they are exposed to relatable role models in entrepreneurship. (3) women stem students demonstrate higher entrepreneurial proclivity when entrepreneurship is presented as a gender-neutral field. (4) women stem students demonstrate higher entrepreneurial proclivity when they are exposed to entrepreneurial success stories. the researchers will make causal inferences about factors that influence entrepreneurial proclivity of women in stem by measuring self-reported activities, analyzing administrative data, and documenting student start-ups. the core of the project is based on data drawn from a data infrastructure that combines administrative data with results of an annual survey. the researchers will use those data to evaluate the mechanisms that influence the underrepresentation of women in entrepreneurship. they will augment the data infrastructure with a

field experiment to test hypotheses informed by existing literature and findings from their data analysis. this project is co-supported by the ehr core research program that funds fundamental research on stem learning and learning environments, broadening participation in stem fields, and stem workforce development and by the science of science bpinnovate program. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Global estimates of energy pathways and stirring by internal waves and vortical mode

Awardee: NorthWest Research Associates, Incorporated

Amount: \$981,611.00

Abstract: the ocean primarily derives its energy from large-scale wind, tidal and solar forcing, but the ultimate distribution of heat and currents depends on how this energy is transferred from large-scale motions to small scales where it is dissipated. some of the energy forced by winds at the ocean surface escapes to the interior through density undulations, called near-inertial waves, that can span hundreds of kilometers. another significant energy source for waves comes from the tide when it encounters topography and produces internal waves, known as the internal tide. it is generally well understood that these two types of waves interact, catalyzed by other flow features, and transfer energy through an internal wave field into smaller scale motions and mixing. this study will parameterize the spectrum of internal waves in terms of the large-scale forcing and other catalysts, and the predicted stirring that results, producing the first global maps of these estimates. parameterizations of these stirring processes will benefit large-scale ocean general circulation models (ogcms), and a refined understanding and parameterization of the internal wave energy cascade and its implications for vertical mixing and dissipation will benefit climate models. recognizing that submesoscale, ogcm and climate modelers at the same meeting often do not

attend the same scientific sessions, the investigators will bring these two communities together by organizing a joint session at the 2024 ocean sciences meeting, focused on internal wave and submesoscale parameterizations in global models. one graduate student will be trained under this project (umassd). the ongoing efforts of the team demonstrates their commitment to education, outreach, **\*\*diversity\*\*** and inclusion. pi sundermeyer currently advises (among others) five women graduate students, and will seek to recruit women and/or under- represented/minority students under this project. pi sundermeyer has given several presentations on ocean processes to multiple classes in the sandwich, ma public school district. under the present project, he and the graduate student will work with middle and high school teachers in sandwich and new bedford public schools to develop ocean-related learning modules. pi early helped design and mentor in an nsf-reu program and co-founded the nwra early-scientist mentoring program; pi wortham is a science communication fellow at seattle pacific science center; pi lelong is a mentor with mpowir and active in the seattle chapter of swms. nwra participates every summer in discovery corps, the pacific science center's summer research program for high school and college students from under-represented communities. this proposal involves collaborations with ogcm modeler h. simmons and with mexican mathematician g. hernandez-duenas.

the internal wave field in the stratified interior of the ocean draws its energy primarily from winds and tides, with geostrophic motions and topographic scattering acting as catalysts. this energy cascades to small scales and directly stirs the fluid, generating vortical mode along the way, which then itself contributes to energy transfers and stirring. although observations indicate stirring rates of  $\mathcal{O}(1) \text{ m}^2 \text{ s}^{-1}$  at scales of  $\mathcal{O}(10) \text{ km}$ , gaps remain in our ability to predict diffusivity at these scales directly from the energy sources. the first major contribution of this study will be to clarify the roles of relevant processes in setting the shape and strength of the internal wave and vortical spectra. second, it will extend previous theoretical and numerical estimates of stirring from internal waves and vortical mode to more realistic conditions. by considering realistic stratification and forcing, this study will close a significant gap in our understanding of how the oceanic internal wave and vortical mode fields are formed, and how these

processes stir fluid at the submesoscale. the work here will also help close the energy budget for the ocean by quantifying the rate at which energy is extracted from various large-scale forcing, and cascaded downscale through the internal wave field. last, it will quantify the shape and magnitude of the vortical mode field that arises naturally as part of this cascade, a result that has remained largely elusive from field observations. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Expanding a Statewide Pathway for CS Teacher Certification: A Curriculum Model for Secondary Education Teacher Candidates

Awardee: University of Alabama Tuscaloosa

Amount: \$978,930.00

Abstract: the university of alabama (ua) will form a researcher-practitioner partnership (rpp) among six alabama higher-education institutions (alabama state university, jacksonville state university, university of alabama at birmingham, university of alabama in huntsville, university of alabama, and university of south alabama), as well as other rpp partners (e.g., high school computer science educators across alabama, and the alabama state department of education). a national plan for expanding k-12 computer science (cs) teacher professional development must include (pre-service) future teacher candidates (tcs) well beyond the current models of only training in-service teachers. this project will contribute to a new approach for virtual online instruction that prepares pre-service tcs as credentialed future cs educators who will introduce their students to computational thinkingskills and concepts. participant tcs will be recruited from a diverse pool of candidates across the six partner institutions and topics of **\*\*diversity\*\***, equity, and inclusion will be a foundation of the two-course pathway. the project is driven by the following core csforall needs: scaling effective professional development (pd) efforts to a large cohort of new cs teachers--many of whom have little

to no formal cs preparation; establishing certification programs and preservice paths for teacher pd; establishing online and hybrid pd approaches, creating robust pd materials for teachers and facilitators; and assessing the effectiveness of pd models with respect to content knowledge, pedagogy, computational thinking, classroom equity, and student outcomes to address these needs, the implementation, research and evaluation of this project will focus on expanding our existing knowledge and impacts from a locally successful and recently completed implementation for training secondary mathematics tcs in cs within their existing mathematics teacher preparation program. the statewide expansion and implementation will widen the geographic coverage to tcs at our partner institutions and broaden the recruitment to all focus areas of secondary education (e.g., science, mathematics, career tech, and even social studies and other teaching fields in secondary teacher preparation). the specific goals of the project include: (1) recruiting and enrolling up to 90 secondary tcs to begin the cs preparation pathway in pursuit of a cs endorsement added to their secondary teaching discipline; (2) producing 72 cs credentialed secondary tcs, of which 27 will receive a course-specific certification for ap computer science principles (csp); (3) producing 45 full cs subject endorsed secondary teachers; (4) leveraging an rpp model that builds beyond a prior effort, this project will provide preparation opportunities that will enable tcs to be ready to teach cs upon graduation, including praxis preparation to become fully credentialed in cs; and (5) expanding and enacting the ua campus cs curriculum for all disciplines of secondary tcs across six higher-education partner institutions, providing an opportunity for openly sharing all developed resources and assisting the partner institutions in bootstrapping their own cs education efforts. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Determinants of amphibian genomic diversity: Integrating traits, phylogeny, and geography

Awardee: University of New Mexico

Amount: \$970,175.00

Abstract: genetic differences between individuals and populations of the same species are essential for organisms to adapt and survive in changing environments. surveying genomic variation within species, and determining what factors influence that variation, are thus important goals for managing wildlife populations and conserving bio\*\*diversity\*\*. amphibians are key contributors to many ecosystem processes, but they are one of the most threatened vertebrate groups. they are also lacking from many comparative studies of genomic variation because they have large, complex genomes. this project will investigate the factors that influence genomic variation within amphibians and will produce new genome-scale data for several dozen frog species sampled across the united states. broader impacts include training early-career scholars including a postdoctoral researcher, two graduate students, and six undergraduate students in field sampling, genomic sequencing, bioinformatics, and statistical analysis. the project will also contribute to research infrastructure by archiving searchable, multi-purpose amphibian specimens and tissues at the museum of southwestern biology for future uses. a new undergraduate course in bio\*\*diversity\*\* informatics will be developed to engage students with natural history collections and bio\*\*diversity\*\* databases, provide computational training, and offer hands-on research experiences through collaborative projects that leverage the amphibian genomic data produced by the project. this research addresses key questions about the determinants of genetic \*\*diversity\*\*, thereby advancing knowledge about the origins, distribution, and evolutionary history of global bio\*\*diversity\*\*. two complementary approaches to data collection encompass several complex factors that affect genetic \*\*diversity\*\* ? life history and ecological traits, phylogenetic history, population history, and current environmental variation ? and provide insights into the scale at which these factors influence \*\*diversity\*\* within species. the first approach will combine data repurposing, machine learning, and phylogenetic comparative methods to identify important predictors of genetic \*\*diversity\*\* for global amphibians using open-access museum, trait, and genetic sequence databases. these results will shed light on the importance of species traits, phylogenetic history, and geographic range

characteristics for predicting genetic **diversity** across hundreds of amphibian species. the second approach will produce new high-resolution, genome-scale data for more than 40 frog species in the united states, sampled strategically across geographic space to test predictions about the influence of population history and current environmental variation on genetic variation within species. by integrating traits, phylogeny, and geography, this research will uncover the determinants of amphibian genomic **diversity** and establish a framework to address this fundamental aspect of **bio-diversity** across different taxonomic and spatial scales. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Testing the most striking tropical marine biodiversity gradient on the planet: does it hold for sponges?

Awardee: University of Hawaii

Amount: \$959,716.00

Abstract: coral reefs are among the most species-rich ecosystems on the planet, occupying only about 1% of the seafloor, but housing more than a quarter of known marine **bio-diversity**. sometimes called the rainforests of the sea, coral reefs have great intrinsic biological, cultural and economic value. nearly a billion people across the planet rely on coral reef ecosystems as a significant source of their diet, and the annual economic benefits of coral reefs are estimated to be around \$9.9 trillion usd. thus, the global decline of coral reefs by an estimated 30-50% since the 1980s is of considerable concern as scientists struggle to understand whether species are being lost before they are even discovered. while coral reefs are spectacularly diverse, the majority of this **bio-diversity** actually lives hidden deep within the three-dimensional framework of the reef itself. this hidden (or cryptic) community of organisms are both dramatically understudied and fundamentally important for the persistence of coral reefs. sponges are a dominant group among

these cryptic organisms within the reef which provide food from the bottom of the food chain and help sustain coral reef bio\*\*diversity\*\*. despite the vital ecological role of sponges on coral reefs, little is known about their \*\*diversity\*\*, abundance or species ranges across the indo-pacific. for example, the most striking marine bio\*\*diversity\*\* gradient on the planet is described from several of the visibly dominant groups on coral reefs, including corals and reef fishes. from the global hotspot of species richness in the indo-pacific coral triangle there is a sharp eastward decline in species numbers to more remote oceanic islands in the central pacific, such as the hawaiian archipelago. however, no survey to date has evaluated whether the \*\*diversity\*\* of poorly known cryptic coral reef species, such as sponges, show the same pattern as the visible species that dominate the surface of the reef. summer training modules introduce at-risk pacific islander youth to coral reef bio\*\*diversity\*\* to recruit and train a new generation of sponge taxonomists. identification guides are being produced to help resource managers in establishing a baseline of sponge \*\*diversity\*\*, which allows resource managers to identify and protect native species, improves detection of alien species introductions and serves as a tool for monitoring changes in the ecosystem in response to human impacts. the work is being disseminated widely through scientific literature, public and professional presentations, popular press articles, and an educational display about sponges and coral reef biology in collaboration with the waik?k? aquarium. this important knowledge gap is addressed by analyzing an existing backlog of standardized sampling devices (arms) collected from throughout the pacific ocean to determine whether sponges that live largely unseen within the reef framework follow the same \*\*diversity\*\* gradient as has been previously reported for fish and corals. by integrating taxonomy with multi-locus dna barcoding and metabarcoding, this project is documenting species richness and bio\*\*diversity\*\* patterns among the cryptic sponge community across five ecoregions spanning over 10,000 km of the tropical pacific. these collections include many new species and are providing vouchered dna barcodes to existing reference databases that currently include fewer than 1% of sponge species across the planet. sponges are a rich source for pharmaceutical development, so discovery of new species also provides opportunity for exploration

of natural products from both the sponges and culturable microbes associated with them. by examining sponge species occurrence and **diversity** along both environmental and anthropogenic gradients in each ecoregion, the data also address whether coral reef sponges can serve as indicators of human impacts. collectively, these results are transforming our knowledge of tropical pacific sponge bio**diversity**, species ranges, and providing much-needed reference barcodes to global sequence databases. by determining whether sponges show the same indo-pacific richness gradient as reported in fishes and corals, this project is testing how well generalizations made from the visible subset of species that live on the surface of coral reefs apply to rest of coral reef bio**diversity**. this study is greatly advancing our knowledge of pacific coral reef sponges and will ultimately inform the scale over which vital ecological roles performed by this understudied taxon, such as the production of nutrients at the bottom of the food chain, are acting across the pacific. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Community Facility Support for Geochronology and Thermochronology at the Arizona LaserChron Center

Awardee: University of Arizona

Amount: \$959,118.00

Abstract: recent developments in geochronologic methods and instrumentation are revolutionizing many different aspects of earth science research. some of the most exciting advances are being driven by laser-ablation icp mass spectrometry (la-icpms), which generates u-th-pb ages and complementary geochemical information rapidly, with micron-scale spatial resolution, and with the precision necessary to address a wide range of problems in earth science. the arizona laserchron center (alc) is a community facility that utilizes la-icpms to determine u-th-pb ages, hf isotope ratios,

and trace element abundances from a variety of minerals that occur in sedimentary, igneous, and metamorphic rocks. we also utilize a dedicated scanning electron microscope that generates the high-resolution and high-magnification images necessary for state-of-the-art micro-analysis. primary goals of the alc are to (1) generate u-th-pb ages, hf isotope ratios, and trace element concentrations of the best precision, accuracy, and spatial resolution possible from la-icpms, (2) provide opportunities for researchers from around the world (and especially nsf-supported scientists) to use our instruments and expertise to address geologic problems, (3) drive the development of new techniques and applications of geochronology, thermochronology, and petrochronology, (4) build new cyberinfrastructure for data acquisition, analysis, and archiving, and (5) use every aspect of facility operation as an opportunity to enhance expertise and **\*\*diversity\*\*** among geochronologists and users of geochronology. research at the alc is conducted in a highly collaborative mode, with alc scientists providing assistance with all aspects of a project (from initial design of the study to final publication of results) and faculty members and students from other institutions visiting the lab to generate their own data and learn the theory and methodology of u-th-pb geochronology. funding from this award will enable the alc to facilitate the acquisition of geochronologic information in support of a large number of nsf-funded projects. these projects focus on generating new knowledge about the growth of continents, emergence of life, processes of mountain building, mechanisms and timing of volcanic eruptions, distribution of sediment through space and time, formation of mineral, energy, and water resources, and linkages between climate and tectonics. the alc will also continue to help drive the development of numerous new analytical techniques, applications, and instruments, as well as the cyberinfrastructure needed to utilize and integrate the information generated. educational activities will include hosting visits from several hundred faculty and student researchers per year, teaching short courses at annual meetings, developing materials that can be used in earth science courses, providing opportunities for non-scientists to learn about geochronology, creating new tools for displaying and interpreting geochronologic data, and driving the development of global databases that host u-th-pb geochronologic information. this award

reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: HSI Implementation and Evaluation Project: Western MA Engineering Pathways Program

Awardee: Holyoke Community College

Amount: \$956,458.00

Abstract: with support from the improving undergraduate stem education: hispanic-serving institutions (hsi program), this track 2 project called the western ma engineering pathways program, will contribute to the national need for a diverse engineering workforce by supporting the recruitment, retention, graduation, and transfer of underrepresented students in engineering programs at holyoke community college (hcc), the university of massachusetts at amherst, and

western new england university (wneu). over a four-year period, the project will identify students from partners holyoke high school and westfield high school who express an interest in engineering, develop and test innovative interventions, and support students along the academic pathway. early engagement with engineering concepts and ongoing comprehensive student supports will bolster stem identity, self-efficacy, and self-confidence among traditionally underrepresented students in the field. the western ma engineering pathways program has three goals: 1) create improved pathways to broaden the participation of students historically underrepresented in engineering, 2) revitalize hcc's engineering programs to be more responsive to a diverse student body and to regional employer demands, and 3) produce fundamental research on building an effective pathway for targeted students in the western massachusetts that can be implemented and sustained in a way that is replicable nationally. with support from project partners at the collaborative for educational services, the society for women engineers (swe), and the 50k coalition, project activities will attract and retain more students in engineering, especially students who identify themselves as women, latinx, or from other historically marginalized groups. the proposed project will investigate the differences between the experiences and decisions surrounding engineering education for women, latinx students, and students with multiple marginalized identities (mmi) in undergraduate engineering education. research questions will determine how high school and community college students make decisions around pursuing undergraduate engineering education; the ways in which latinx and female students, especially those with mmi, differ in their decision-making process from their peers; how institutional changes made to address the needs of latinx students, especially those with mmi, improve their outcomes and those of other undergraduate engineering students; and how equitable pathway design can be used to shift stakeholders' foci from institutional outcomes to student-centered outcomes. findings from this project will support equity and inclusion efforts at each partnership institution and will guide efforts at other hispanic-serving institutions seeking to increase latinx contributions to the future of engineering. the project team will work with the 50k coalition to share promising practices and stem education research findings on a national scale.

improved connection and interaction with local industry will provide employers with a voice in preparing future engineers and increasing **\*\*diversity\*\*** in their workforce. the hsi program aims to enhance undergraduate stem education, broaden participation in stem, and build capacity at hsis. achieving these aims, given the diverse nature and context of the hsis, requires innovative approaches that incentivize institutional and community transformation and promote fundamental research (i) on engaged student learning, (ii) about what it takes to diversify and increase participation in stem effectively, and (iii) that improves our understanding of how to build institutional capacity at hsis. projects supported by the hsi program will also draw from these approaches to generate new knowledge on how to achieve these aims. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: CAREER: Predicting plant functional trait variation across spatial, temporal and biological scales

Awardee: Virginia Commonwealth University

Amount: \$950,561.00

Abstract: variability is an inherent property of life on earth. as a result, understanding the causes and consequences of variability is central for understanding the nature of life itself. as mean temperatures increase around the world, many areas are simultaneously experiencing increasing climatic variability. yet, there is no theory that predicts the variability of natural systems. this research will develop a model for predicting the variability of plant function across scales of biological organization, from organisms to ecosystems. this research will focus on plant functional traits (morphological, physiological, and phenological characteristics) and environmental variability because functional traits link plant performance to ecosystem processes. further, gradients of environmental variability are ubiquitous in nature across all spatial and temporal scales, and underlie

prominent ecological and evolutionary hypotheses. in addition to developing new theories and generating new data essential for predicting species responses to increasing climatic variability, this project will address a national training need in data literacy, data science, and working with different scientific disciplines. to do so, undergraduate course content and training modules will be designed following open science principles. course content will leverage open biological and environmental data produced by nsf investments in research and infrastructure, including the national ecological observatory network (neon), the long-term ecological research (lter) network, integrated digitized biocollections (idigbio), and the global bio\*\*diversity\*\* information facility (gbif). additionally, this project will support the training and professional development of students from historically underrepresented groups in science, contributing to a diverse, skilled, and innovative stem workforce. specifically, this research will quantify emergent properties of functional trait variation by decomposing trait-trait and trait-environment relationships; testing the environmental heterogeneity and climatic variability hypotheses; and linking trait variation at the organismal scale to patterns of species distributions. at a continental scale, this project will leverage data from neon sites across latitude encompassing the eastern united states and puerto rico to quantify plant trait variation across spatial, temporal and biological scales. this project will also characterize scaling between plant functional trait variation, environmental heterogeneity, and climatic variability across temperate and tropical mountains, where abiotic gradients in temperature and precipitation are steep in space and time. measurements of plant abundance, growth, functional traits, and satellite observations of vegetation indices will form one of the few explicit tests of the environmental heterogeneity and the climatic variability hypotheses across spatiotemporal scales. ultimately, this research will resolve major disparities in the measurement, quantification, and modeling of functional trait variation. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Pollen-stigma interactions: events and players that set off the path to reproductive success

Awardee: University of Massachusetts Amherst

Amount: \$950,000.00

Abstract: pollination in flowering plants is the requisite process for fertilization. the production of seeds and fruits, preservation of plant species and generating **\*\*diversity\*\*** all rely on pollination success. this project focuses on understanding how pollen and stigma, the pollen receptive surface on the pistil (the female reproductive organ) interact to initiate pollination. the first event on the stigma is for the pollen to germinate, thereby generating a pollen tube which penetrates the stigma and elongates inside the pistil to deliver sperm to the egg. the mechanisms underlying the activation of dormant pollen grains are poorly understood. the process requires the pollen cytoplasm to distribute to a small area where a pollen tube emerges from the grain and grows into the pistil to start a fruitful journey. this project focuses on obtaining a molecular understanding of these earliest pollination events. water transfer between the stigma and pollen to activate the pollen grain, cytoplasmic reorganization in the pollen to engineer the tube extrusion and tube growth process, and the enzymes that modify the pollen and stigma cell walls to facilitate tube extrusion and its penetration of the pistil will be examined for their contribution to the success of the early pollination events. the project will train undergraduates, master?s, ph.d. students, and post-graduate level scientists, feeding the pipeline for the research workforce and future leaders in science. a collaboration with girls inc. of the valley (holyoke ma) will bring high school girls for a summer experience centered on the project research area.

important advances have been made in recent years in the molecular and cellular understanding of the reproduction process in flowering plants, especially in how the sperm-bearing pollen interact with tissues in the pistil to enable fertilization to produce seeds. important but under-explored are the earliest events which occur upon pollen landing on the receptive surface of the pistil, the stigma, to set off the pollination process. this project focuses on obtaining a molecular and cellular understanding of these early events. specifically, the project explores how the stigmatic papilla cells mobilize water from the stigma to

hydrate a dry and dormant pollen grain to activate germination, which involves the extrusion of a polarized outgrowth from the grain and its development into a pollen tube. it also examines how the pollen grain mobilizes its cell surface signaling and cytoplasmic components to orchestrate pollen tube extrusion and penetration of the stigma. considerable cell wall degradation and modification activities occur in both the pollen and the pistil to enable the germination and tube growth process. therefore, how cell wall degradative enzymes contribute to these processes will also be examined. the research uses arabidopsis as the model system and relies on combined molecular, transgenic, cell biological and biochemical approaches. the project will provide students from undergraduate to postdoctoral levels with a broad range of scientific knowledge and experience in research approaches that can be broadly applied. a summer workshop related to plant reproduction will be developed for high school students from neighboring inner cities. the cellular dynamics and function cluster in the division of molecular and cellular biosciences is co-funding this award. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: RoL: The Evolution of the Genotype-Phenotype Map across Budding Yeasts

Awardee: Vanderbilt University

Amount: \$949,986.00

Abstract: how organisms' external characteristics or traits are encoded in their genomes and how they change over time represent important and largely unanswered biological questions. this project will address these questions by studying the metabolisms and genomes of the more than 1,000 known species of budding yeasts and their evolution. some of these yeast species are important opportunistic pathogens, while others are of great industrial relevance as producers of foods, beverages, medicines, and biofuels. this project will span multiple scales of biological organization

(from molecules to cells, species, and beyond) and ~400 million years of evolution to yield fundamental insights into how traits are encoded in genomes, how new functions evolve, and how the relationship between traits and genomes itself evolves. the project will support the wild yeast and computational genomics programs, two established and highly successful educational and training programs that immerse early-stage undergraduate students, including those from underrepresented backgrounds, in authentic, discovery-driven research. using draft genomes for nearly all known budding yeast species and state-of-the-art genome-editing tools that are broadly active in diverse species, this project will predict the connection of every metabolic gene in every yeast species? genome to its function(s), as well as examine the evolution of every known metabolic gene, pathway, and trait across the budding yeast subphylum saccharomycotina. through genome-scale evolutionary analyses and targeted functional experiments on key representative taxa spanning budding yeast genomic and metabolic **\*\*diversity\*\***, this project will functionally characterize how between-taxa variation at the level of genotypes gives rise to variation at the level of phenotypes. in particular, the project will chart how variation at the level of dna, rna, proteins, and metabolites sequentially transforms genetic variation into biochemical functions and physiological traits with an emphasis on functionally characterizing gaps and correcting discrepancies in the predicted genotype-phenotype map. this project is jointly funded by the evolutionary processes program in the division of environmental biology and the genetic mechanisms program in the division of molecular and cellular biosciences of the directorate for biological sciences. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Citizen Science Teachers: Noyce Residency Scholars Program for Western New York

Awardee: SUNY at Buffalo

Amount: \$946,530.00

Abstract: this project aims to serve the national need of increasing the number and retention of diverse and effective science teachers in high-need school districts in western new york. with a citizen science focus, this project will explore innovative strategies for preparing science teachers through civic engagement, study of local environments, and transformational approaches sustained in partnership with schools and communities. this focus will be paired with a context-specific, community-based teacher residency approach, a model that research has demonstrated to produce teachers who reflect greater demographic **diversity** and have notably longer retention as teachers. taken together, a citizen science focus and residency approach may yield project outcomes that shed light on recruiting, preparing, and retaining high-quality science teachers that reflect the demographic **diversity** of students in p-12 schools. this project at the university at buffalo includes partnerships with buffalo public schools and niagara falls city schools. the project's overall goal is to recruit, prepare, and retain 20 science teachers across five cohorts of science career changers and undergraduate biology, chemistry, physics, and earth science majors. it is expected that project will contribute to a deeper understanding of how a civic engagement approach to local environments, when paired with a community-based approach to field experiences, can yield high quality, culturally, and linguistically-diverse teachers who have a positive impact on science engagement and learning in p-12 schools. using surveys, interviews, and data about participation, retention, and academic performance, this project will examine the effectiveness of the project's interventions in preparing and engaging science teachers, and in placing and retaining these teachers in high-need schools. project outcomes will be analyzed by building a series of statistical models, such as cross-sectional sem models and longitudinal models. quantitative data will be triangulated with qualitative data to provide a more rigorous assessment of project impact. project findings will be disseminated in journals, at conferences dedicated to stem teacher preparation as well as venues open to increasing the **diversity** of the ranks of stem teachers, and through online reports and monographs. findings can inform teacher education programs across the country regarding diversifying teachers in p-12 schools, with a particular focus on science teachers. this

project also supports research on p-12 students? science learning experiences and the impact of civically engaged science instruction facilitated by teachers from diverse backgrounds. this track 1: scholarships and stipends project is supported through the robert noyce teacher scholarship program (noyce). the noyce program supports talented stem undergraduate majors and professionals to become effective k-12 stem teachers and experienced, exemplary k-12 teachers to become stem master teachers in high-need school districts. it also supports research on the persistence, retention, and effectiveness of k-12 stem teachers in high-need school districts. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Genomics of speciation and evolution of ecological traits in a geographic radiation of island kingfishers

Awardee: University of New Mexico

Amount: \$942,923.00

Abstract: how and why species diversify is a central question of biology and the process of speciation is how all bio\*\*diversity\*\* is created. islands provide an excellent setting in which to study speciation in wild populations due to their discrete geography and well-characterized geologic record. the indo-pacific, from southeast asia to polynesia, is the cradle of speciation theory and home to numerous geographic radiations of widespread, rapidly evolving species complexes. this project will synthesize genomics and state-of-the-art trait datasets to reveal processes that promote rapid radiations in nature. specifically, it will use a widespread, species-rich genus of island kingfishers (aves: todiramphus) as its study system. this project aims to make broadly applicable and generalizable predictions about the speciation process. the outcomes of this project will be a model for future speciation research in the pacific and serve as a springboard for pioneering new ways of studying complex phenotypes and their interactions with nature. this project will engage the

public through virtual and face-to-face experiences. the researchers will create virtual collections experiences (vces) that highlight the associated natural history collections at the museum of southwestern biology and the field museum. these online tools will reveal how data are collected from specimens and used to address the project's research objectives. the vces will be developed as education modules for grades 9-12, complete with lesson plans and student learning outcomes. the researchers will develop a highly multisensory exhibit at the field museum, playing on the project's themes of color evolution that will reach an estimated 500,000 people in chicago. an educational workshop will be held at the museum of southwestern biology that will provide hands-on training and experience in bio\*\*diversity\*\* science to native american and hispanic students from unm and new mexico's rural-area institutions. it will showcase professional opportunities in stem with a focus on museum-based bio\*\*diversity\*\* science. speciation genomics addresses the roles of ecology, gene flow, and genomic architecture in the formation of species. this project proposes an integrative study of systematics, biogeography, plumage diversification, and ecological adaptation to test multiple hypotheses of the factors that promoted rapid diversification in a diverse and widespread radiation of island kingfishers. todiramphus kingfishers occur across the entire indo-pacific and their diversification rate rivals those of 'classic' adaptive radiations. this study system provides replicated instances of sympatry and isolation, as well as divergent ecologies required for a synthetic study of diversification. the project will generate diverse datasets including whole genomes, ecological niche models, and phenotypic traits, to study how these factors facilitated rapid radiation on islands over the last 10 million years. the proposed research will leverage this unique geographic context to provide novel insights into the multifaceted process of speciation by (a) quantifying the presence and extent of gene flow and how novel changes in genomic architecture influenced diversification; (b) assessing how extrinsic traits (plumage coloration, biogeography, and relative niche conservatism) promoted or inhibited species divergence in the clade; and (c) through a novel test of the abundance-niche-center hypothesis in the context of genomic and phenotypic \*\*diversity\*\*. this award reflects nsf's statutory mission and has been

deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Quorum Sensing Control of Bacterial Biofilm Formation and Dispersal

Awardee: Princeton University

Amount: \$934,613.00

Abstract: biofilms, bacterial communities formed on solid surfaces, are a predominant form of bacterial life on earth. biofilms are crucial for the environment, industry, and medicine. biofilms can be beneficial, for example in the microbiome and in bioremediation, but biofilms can also be harmful, for example during infection and because biofilms foul many types of surfaces. biofilm dispersal is

crucial for bacterial spread and for disease transmission, but very little is known about this important process. one aim of this project is to determine the mechanisms that coordinate biofilm dispersal. another aim of this project is to determine how communication between bacterial cells helps maintain biofilms. an exploration of the role of phages in driving biofilm formation and dispersal will also be a focus of this work this work will advance the progress of science by revealing the mechanisms that provide bacterial biofilms their resilience and they will reveal biofilm vulnerabilities. highly talented students will be trained by working on this project. efforts to increase **\*\*diversity\*\*** among those who participate in science research and efforts to expand public access/public understanding of science are central to the project and will be accomplished through a variety of nation-wide science outreach efforts. the overall goals of this research are to explore the mechanics, spatial and temporal cell-cell communication processes, and signal transduction networks that enable bacteria to build and subsequently disassemble multicellular biofilm communities. an exploration of the role of phages in driving biofilm formation and dispersal will be a focus. the studies will span biological scales - from the molecule, to the protein, to the network, to the cell, to the community. at a basic science level, the work will define the mechanisms bacteria use to uniquely detect and respond to kin and non-kin in communities, how genes and mechanics interact to drive community morphology, and how inter-domain interactions influence multicellular community dynamics. at a practical level, these investigations could lead to synthetic strategies to manipulate biofilm formation and dispersal, quorum-sensing-mediated communication, and phage infection of bacteria. consequently, the results should reveal the principles underpinning the evolution and maintenance of traits that are not essential under laboratory conditions but are crucial and precisely regulated in nature. with this knowledge in hand, the field should be able to rapidly move forward to develop synthetic strategies to prevent or promote quorum sensing, to prevent or promote single-species and mixed-species biofilm formation, and to prevent or promote biofilm dispersal, as required. such applications will have industrial, agricultural, and medical relevance. the pi is highly involved in service as chair of department, as a teacher, as an editor, broadly in national

educational and outreach initiatives, and through her service to not-for-profit foundations and government funding agencies. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Accessible Computational Thinking in Elementary Science Classes within and across Culturally and Linguistically Diverse Contexts

Awardee: Arizona State University

Amount: \$931,058.00

Abstract: currently, students who are white, affluent, and identify as male tend to develop a greater interest in and pursuit of science and computing-related careers compared to their black, latinx, native american, and female-identifying peers. yet, science, computing, and computational thinking drive societal decision-making and problem-solving. the lack of cultural and racial **\*\*diversity\*\*** in science and computing-related careers can lead to societal systems and decision-making structures that fail to consider a wide range of perspectives and expertise. teachers play a critical role in preparing students to develop these skills and succeed in a technological and scientific world. for this reason, it is crucial to investigate how teachers can help culturally and linguistically diverse students develop a greater understanding of and interest in science and computers. this research project aims to enhance elementary teacher education in science and computational thinking pedagogy through the use of culturally relevant teaching, i.e. teaching in ways that are relevant to students from different cultural and linguistic backgrounds the project will support 60 elementary teachers in summer professional development and consistent learning opportunities during the school year to learn about and enact culturally relevant computational thinking into their science instruction. in doing so, the project aims to increase both the quantity and quality of computing experiences for all elementary students and support nsf's commitment in broadening participation in

the stem workforce. the project will also produce resources, measures, and tools to support elementary teachers to do this kind of work, which will be shared with other stem researchers and teacher educators. the goal of this research project is to design and promote teaching practices that integrate computational thinking in the elementary science classroom in culturally relevant ways. this project will seek to empower practicing elementary teachers? approaches to meaningfully and effectively integrate and adapt computational thinking into their regular science teaching practice so that all students can access the curriculum. it will also explore the impact of these approaches on student learning and self-efficacy. the scope of this project will include working with multiple highly distinct school settings in maryland, arizona, and washington dc across three years, reaching approximately 60 elementary teachers and 1,200 students. to achieve the project objectives, the research team will leverage concurrent mixed methods approaches that include teacher and student interviews, reflections, observations, descriptive case study reports as well as regression and multilevel modeling. the project?s findings will inform the fields? understanding of: (a) teachers? conceptualization of computational thinking; (b) the barriers elementary teachers encounter when trying to integrate computational thinking with culturally relevant teaching practices; (c) the types of support that are effective in teacher professional development experiences and throughout the school year; and (d) the development of a cohort of teachers that can maintain integration efforts in different districts. the discovery research prek-12 program (drk-12) seeks to significantly enhance the learning and teaching of stem subjects by prek-12 students and teachers, through research and development of innovative resources, models and tools. projects in the drk-12 program build on fundamental research in stem education and prior research and development efforts that provide theoretical and empirical justification for proposed projects. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Developing Authentic and Fair Computer Science Assessments

Awardee: University of Washington

Amount: \$913,449.00

Abstract: this project aims to promote equitable design of computer science (cs) assessment in secondary and post-secondary education in the united states and globally, increasing the **\*\*diversity\*\*** of students engaging in cs learning through reduced test bias. in this study, we aim to address difficulties in assessing computer programming by investigating critical characteristics of programming tasks using both response process and product data. findings will have direct practical implications for developing authentic, fair and valid assessment of learners with different demographic backgrounds. through advancing our understanding of the cognitive processes underlying programming thereby informing ways to better teach, learn, and assess programming skills, we expect the project to impact the broader cs education community through shareable data sets to the general public, assessment innovations in large cs classrooms, actionable insights on test bias for cs instructors, and the engagement of undergraduates of diverse gender, race, and ability. the research team from the university of washington also intends to integrate scientific discoveries from this study into the university's publicly available course materials. the planned dissemination will maximize outreach to various outlets such as the nsf-supported exploring computing education pathways that brings together state leaders shaping u.s. k-12 cs education curricula, practices, and standards. this project consists of foundational research on assessing, learning and teaching computer programming skills. the project will capitalize on the ability of recording the coding process via keystroke logs to extract and summarize vast amounts of fine-grained information captured by observing program edits. we aim to study the relations between process and task characteristics, identifying patterns that are indicative of proficiencies and suggest fluency or dysfluency. such identification will, in turn, allow for designing instructional, learning, or assessment materials that are targeted at specific needs of learners. we plan to triangulate different types of student data to address research questions around detecting meaningful behavioral

patterns from timing and process data when students are engaged with computer programming, relations between tasks characteristics and programming process, student knowledge, attitudes, experience and proficiency, as well as the extent to which task design contribute to the performance patterns detected for students that vary along gender, ethnicity, and native language. the project will use controlled experiments and cognitive interviews to collect quantitative and qualitative data. multiple instruments will be used for data collection, such as the ets major field test-computer science. in terms of data analysis, the project will leverage various analytical and modeling techniques from the fields of psychometrics, statistics, machine learning, and educational data mining. findings from this project will offer empirically-tested guidelines on which task characteristics to account for when designing fair and valid assessments across different demographic groups. this project is funded by the ehr core research (ecr) program, which supports work that advances fundamental research on stem learning and learning environments, broadening participation in stem, and stem workforce development. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Transitions: Modeling microbial community metabolic interactions under extreme conditions

Awardee: Duke University

Amount: \$899,031.00

Abstract: this goal of this research is to determine how microbes living in extreme conditions communicate metabolically. microbial extremophiles are remarkable examples of life's resilience, thriving in hot springs at boiling temperatures, in brine lakes saturated with salt, and in deserts once thought to be sterile. this project uses extremophiles that live in high salt as a test system to map and model how nutrients flow through microbial communities, enabling resilience during times of food scarcity. the metabolism of salt-adapted microbes is poorly understood but produces chemicals

and enzymes of interest to biotechnology. the proposed research is therefore expected to reveal general principles of biological resilience and present novel approaches for future industrial applications of extremophile metabolic products. these activities will enable a transition in the pi's research direction from molecular experiments in pure laboratory cultures to field ecology and metabolic modeling. the goal of the education plan is to foster inclusive learning experiences that span disciplinary lines. together with students and postdocs from her group, the pi will form "co-learning teams" in which the team leader learns, alongside students in the field, how to sample and collect data. in these vertically integrated teams, the perspective that everyone is learning together is expected to lessen power dynamics and promote a positive research culture where all team members feel welcome and valued.

the proposed research tests the hypothesis that hypersaline microbial communities interact to maintain stability despite changes in salinity and nutrient availability. hypersaline-adapted archaea, or halophiles, provide a unique model for investigating the metabolic interactions in microbial communities. member species share a common hypersaline habitat but exhibit extensive **diversity** in how they generate energy. nutrients are intermittently available in hypersaline lakes during seasonal variation, resulting in severe energy stress. in response, halophiles have evolved a wide array of possible metabolic solutions to survive on the same pool of scarce resources. hypersaline microbial communities have great potential to reveal general principles of community resilience to environmental perturbation. however, knowledge regarding the mechanisms of community interactions remain largely uncharacterized. in the proposed work, the pi and collaborators address these questions by pursuing the following objectives: (a) constructing constraint-based models for hypersaline communities to explain and predict metabolic interactions; (b) sampling the great salt lake microbial communities over temporal and spatial gradients to test model predictions; (c) testing model predictions in synthetic communities grown in the lab under ecologically relevant conditions. to accomplish these aims, a comprehensive professional development plan is proposed, including intensive study in metabolic modeling and training in field ecology during trips to the great salt lake. the proposed models are

expected to enable highly accurate predictions of flux distributions in microbial communities. this research enables the pi to launch a new and exciting research direction, building on prior work that discovered mechanisms of transcriptional regulation of metabolic networks in archaeal extremophiles. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: SBIR Phase II: Bilingual Literacy Assessment and Skill Tracker

Awardee: LangInnov

Amount: \$898,537.00

Abstract: the broader impact/commercial potential of this small business innovation research (sbir) phase ii project is related to the underserved, emergent bilingual population in us school systems. in spite of their growing size (approximately 20 percent of the total us population), emergent bilinguals still do not have adequate support to succeed in academic settings and are often victims of a subtractive bilingualism process that favors the acquisition of english at the expense of the home language. the lack of adequate bilingual resources has led to a disproportionate misplacement of emergent bilinguals in special education as well as an increased drop-out rates in bilingual populations, in general, and latino communities in particular. to address these problems, a recommendation system powered by machine-learning algorithms that will generate a personalized bundle of fun, bilingual literacy activities linked to a fully-automated bilingual assessment is proposed. the unique characteristic of this solution is that the personalized activities are generated

automatically based on assessment results and activity performance. the goal of the activities is to develop the skills identified by the assessment as needing improvement, both in english and in the home language of the child. this small business innovation research phase ii project addresses the educational needs of the growing, school-age, emergent bilingual population (i.e. children in the school system whose home language is not english or only english), as well as the loss of cultural **\*\*diversity\*\*** and linguistic acumen for society as a whole. the main research objectives involve: a) designing game-like bilingual activities that can get the young child?s attention, b) developing age-appropriate and culturally-sensitive content for the bilingual activities, c) refining the speech recognizer to work well with children's speech in both spanish and english, and d) implementing the latest trends in data-analysis and machine-learning technologies to develop a recommendation system that proposes personalized activities tailored to each child?s needs based on assessment results and activity performance. the research and development plan aims at developing an innovative product that stands out from existing solutions. the key differentiator features are: 1) its focus on bilingual children and its adaptability in accepting bilingual answers for the activities, 2) its capacity to help children develop speaking skills due to the integration of automatic measures of speech performance, and 3) its recommendation engine that suggests personalized bilingual activities for each student tailored to their specific needs. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: MIM: The impact of the fungal microbiome in metal tolerance and soil biogeochemical transformations

Awardee: Michigan State University

Amount: \$898,475.00

Abstract: some metals are essential nutrients for life, while some are non-essential or even harmful

to living organisms. fungi and bacteria are microorganisms that often live in a close association and play a key role in transforming and detoxifying metals in the environment. in spite of this importance, there is relatively little understanding of how the interactions between bacteria and fungi influence the transformation and/or detoxification of metals. the goal of this project is to address this knowledge gap by identifying how fungal-bacterial interactions affect metal transformation. this will be achieved through a novel multidisciplinary research approach employing advanced, state-of-the-science analytical techniques. knowledge gained through this project will allow the engineered control of metal transformations for a wide range of applications in environmental cleanup, biorefining, production of nanoparticles, and other beneficial applications. successful completion of this research has strong potential to benefit society through improvements in environmental remediation and industrial manufacturing. this project will improve the nation's stem workforce by providing a unique training opportunity for student researchers that bridges diverse fields such as environmental engineering, microbiology, geochemistry, bioinformatics, and art.

remediation of metal contamination is a major environmental challenge because, unlike many organic pollutants, metal species cannot be degraded and can only be extracted or biotransformed to less toxic forms. while past approaches to biotransform metals have focused primarily on single microorganisms, host-microbiome interactions have shown potential to biotransform surrounding environments and improve host resiliency. however, the mechanisms for metal biotransformation by microbial host-microbiome systems are largely unknown. the overall goal of this project is to elucidate the rules of life that govern fungal microbiomes. this goal will be achieved through a specific focus on fungal microbiomes, which include a fungal host, endosymbionts (endobacteria), and symbionts (exobacteria that live extracellularly) as a model host-microbiome system. the specific research objectives of this project designed to achieve the goal are to: understand the effects of metals and metalloids on the **\*\*diversity\*\*** and transmission of fungal microbiomes (facultative and obligatory); and determine the role of fungal microbiomes in metal tolerance by mediating the uptake, transformation, and sorption of metal ions, nanoparticles, or other metal

species. a deeply integrated multidisciplinary approach will be used to investigate physiological, genetic/genomic, and metabolic processes that govern the structure and function of fungal microbiomes in the presence of metals. this will be achieved using novel state-of-the-science isotope probing, advanced microscopy, spectroscopy, and integrated genomics, transcriptomics, and metallomics to elucidate how the microbiome influences the metabolic activity of the host towards metal ions. successful completion of this research has strong potential to identify new genes and/or pathways for metal tolerance and biotransformation, as well as expand our mechanistic understanding of the structure and function of fungal microbiomes in nature. this knowledge has strong potential to benefit society by facilitating applications in remediation, water treatment, electronics manufacturing, antimicrobial production, medicine, and related fields. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Genome editing approaches to unravel microRNA roles in stochastic multistable networks

Awardee: Northeastern University

Amount: \$896,200.00

Abstract: one of the fundamental questions in biology is to understand the roles of the gene regulatory networks driving cellular decisions; cellular decisions drive everything from an organism's development to a cell's fate as healthy or diseased. micrornas (mirnas) are small rna molecules that bind to the mrna of target genes, acting as regulators of gene expression. previous studies have demonstrated the critical roles of mirnas in a variety of biological processes such as cell growth and cell differentiation. however, what is still not well understood concerns possible synergistic effects from multiple mirna molecules targeting different binding sites of the same mrna and concerns how mirna interactions operate within a complex gene regulatory network. to address these issues, an

interdisciplinary platform that combines genome editing, live-cell imaging, and mathematical modeling will be developed in this project. the broader impacts of the project from the university of texas at dallas side will include support for the international genetically engineered machine (igem) team and developing custom educational modules for local schools (plano isd) and summer camps, organizing public educational events at the interface of the biological and physical sciences, and the recruitment of underrepresented minorities. from the northeastern university side, the group will take advantage of the investigators' participation in the nsf center for theoretical biological physics ongoing **\*\*diversity\*\*** efforts to recruit undergraduates from under-represented to work on this project, and spearhead an effort to create a modeling and computational track for undergraduate bioengineering majors. finally, both groups will be directly involved in reaching out to local biomedical groups to create more appreciation for the types of rapid progress that can be made by combining advanced tools such as crispr with state-of-the-art computational methodology including both mechanistic studies and machine learning approaches. lying at the heart of intricate relationships that determine the epithelial-mesenchymal transition (emt) and mesenchymal-epithelial transition (met) phenotypes is a core regulatory unit that consists of transcription factors and micrnas. the project will focus on mirnas targeting the master transcription factor (tf) families of emts, snail and zeb during the cellular decision process of emt in multiple cell lines. the team will first perform crispr-based screens and custom genome and base editing modifications on mirna binding sites that are located at the 3'-utr of the transcription factor families snail and zeb. the effects of binding site modifications in emt and isolated respective clones will be evaluated. second, the team will prepare and optimize an rna imaging platform in live cells and measure time-series data and population distributions for mirna, mrna and protein levels of corresponding genes. using this data, the team will develop stochastic kinetic models of mirna regulation and infer the combinatorial effects of multiple mirna species binding to multiple sites of the same mrna. third, the team will integrate the kinetic models for each mirna interaction into full transcription factor-mirna network models for different cell lines. the models will be refined by calibrating model predictions with

experimental observations on the distributions of gene expression and the distribution of cells in various emt states. this project brings together investigators who have extensive experience in genome editing/systems biology (bleris), epithelial?mesenchymal networks (levine), and systems biology/mathematics (lu). this award reflects nsfs statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Precision Measurement of the 1S-2S Interval in Positronium

Awardee: University of California-Riverside

Amount: \$891,952.00

Abstract: general audience abstract: the positronium atom (ps) is an exotic short-lived atom formed by an electron and its anti-particle, the positron. this project will improve the accuracy of measurements of the structure of ps, revealing detail about the fundamental interactions between the electron and positron. unlike more conventional atoms ps does not contain any protons or neutrons; thus spectroscopy of ps atoms is an excellent test of ?bound-state quantum electrodynamics,? the cornerstone theory for modern atomic physics. this project pushes the state-of-the-art in the ultra-high precision measurement of short lived atoms and molecules and opens the door to better understanding of transient chemical species that are produced as a reaction is taking place. graduate students will build and operate the apparatus designed especially for this experiment. undergraduate students will assist in the experiments, mostly during the summers. local high school teachers will attend a week-long university of california riverside summer academy for high school teachers at which teachers are exposed to research, visit the labs, and are inspired by lectures and demonstrations that explain how to incorporate research within the high school physics curriculum. the pi will visit high school physics teachers and classrooms and work with local county board of education science projects to advance junior and senior high school

curriculum development under the new next generation science standards and state science standards. this project will thus help expand the nation's high technology work force by training students in cutting edge techniques and increase the **\*\*diversity\*\*** of participants in stem fields, starting with the pipeline from junior high school physical science classrooms.

technical audience abstract: the purely leptonic positronium (ps) atom is uniquely well-suited for testing bound-state quantum electrodynamics (qed). high accuracy ps spectroscopy at the few parts per trillion level will provide background information that can be used to extract non-qed physics out of precision atomic measurements with heavier leptons and hadrons. in this way, ps spectroscopy can shed light on the proton charge radius puzzle as well as the recent shifting of the value of the rydberg constant (by about 7 times the previously accepted experimental uncertainty). whenever a measured constant is shifted by such a large amount, then there is an opportunity for closer examination to yield new experiments and new physical understanding in how to measure the constants. higher accuracy can also help constrain higher level recoil effect corrections in muonium. the previous precision measurement of the ps 1s-2s interval,  $1,233,607,216.4 \pm 3.2$  mhz, performed by the co-pi and s. chu has stood for 25 years. the uncertainty in this measurement came from positronium atoms spending too little time in the laser beam (transit time broadening), atoms moving too fast (second-order doppler shift), laser intensity too high (ac stark shift), and metrology limited at the  $\sim 1$  mhz level. this project will implement several new techniques to improve accuracy and precision. a position-sensitive time-of-flight detector will record the trajectory and speed of every detected atom as it passes through a larger laser beam profile, and thereby reduce the uncertainty due to second-order doppler shifts, ac stark shifts, and transit-time broadening. a frequency-comb and a frequency-beat technique will be used to monitor the instantaneous laser frequency as positronium atoms transit the excitation beam. these innovations should reduce the uncertainty in the measurement by a factor of 300, with the goal of reaching a 10 khz uncertainty. this work will train graduate students in a combination of atomic physics, positron science, laser spectroscopy, and metrology. this training will benefit the students as well as the nation by providing highly skilled

ph.d.'s for the scientific workforce. the university of california riverside is a department of education designated hispanic serving institution (hsi) with 50% of physics majors and 10% of domestic graduate students from under-represented ethnic minority groups. several undergraduate researchers and a high school teacher will also be involved in these experiments, and this will help to attract more participants to stem disciplines. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Dimensions US-China: Collaborative Research: Consequences of diversity in Asian and American tree symbionts for functional variation, adaptation and symbiont biodiversity

Awardee: University of Minnesota-Twin Cities

Amount: \$890,075.00

Abstract: the world's approximately 425 oak species maintain species identity even while exchanging genes with their close relatives through hybridization. this history of evolution and genetic exchange has shaped the bio\*\*diversity\*\* of northern hemisphere ecosystems. oaks are ecologically diverse, with related species often growing in close proximity but specializing on areas of the forest landscape that differ in soil texture and moisture level or in the frequency of natural fires. gene exchange can move such ecological specializations between oak species, broadening their ranges and ability to respond to climate change. the impacts of these genetic exchanges may extend beyond the oaks themselves. oaks host an estimated 1000 gall wasp species worldwide and highly diverse communities of fungi associated with their roots (as mycorrhizae) and inside their leaves (as endophytes). using paired field surveys and common garden experiments the p.i.s will evaluate the effects of hybridization and introgression on the genetic, phylogenetic, and functional \*\*diversity\*\* of focal oak species and their symbionts in the us and china. this work will also provide inquiry-based k-12, undergraduate, and graduate education; critical natural history training to the

public through a community-science initiative in oak phenology; and publications that will bring research to public audiences. two interdisciplinary teams of researchers, one based in the us and one in china, will investigate how genomic, functional, and phylogenetic **\*\*diversity\*\*** of oak trees shape the mycorrhizal fungi, endophytic fungi, and gall wasp and other insect communities that associate with them. research will focus on two related groups of interbreeding species: bur oak (*quercus macrocarpa*) and relatives in the us and bao li (*quercus serrata*) and relatives in china. the project has three objectives, each conducted in parallel in china and the u.s. in objective 1 the teams will perform range-wide phylogenomic surveys of natural populations to reconstruct genomic mosaics, characterize geographic patterns of leaf functional traits, and characterize functional and phylogenetic **\*\*diversity\*\*** of associated mycorrhizal fungi, leaf endophytic fungi, and gall wasps. in objective 2 common gardens will be planted across climatic gradients to evaluate the effects of genetic variation and population differentiation on oak functional and spectral traits and relative fitness in different climates, and how these influence the phylogenetic and functional **\*\*diversity\*\*** of oak-associated fungal and insect communities. in objective 3 the teams will use a second set of common garden experiments to evaluate how plant community and phylogenetic **\*\*diversity\*\*** affects focal oak species genetic, phylogenetic, and functional **\*\*diversity\*\***. the project will provide an integrative perspective on how oak **\*\*diversity\*\*** within and among species impacts the broad **\*\*diversity\*\*** of oak-dominated ecosystems across the northern hemisphere. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: MRI: Acquisition of a High Temperature and Pressure Solid-state NMR Spectrometer

Awardee: Washington University

Amount: \$886,362.00

Abstract: the award supports the acquisition, installation, and shared research application of a

state-of-the-art solid-state nuclear magnetic resonance (ssnmr) spectrometer system in the nano research facility/jens molecular and nanoscale analysis laboratory (nrf/jens lab) at washington university in st. louis, missouri (wustl). the ssnmr system is capable of high-temperature and high-pressure sample analysis, thus opening the door to the study of a broad range of critical environmental remediation, biological processing, and fuel/chemical/polymer manufacturing technologies under realistic conditions. primary research areas include: (1) homogeneous and heterogeneous catalysis, (2) membrane-based separations, (3) polymeric and biological materials properties, and (4) geochemical and biogeochemical systems (e.g., carbon sequestration). the system will support a broad user base consisting of researchers at multiple universities in the midwest region surrounding st louis (including missouri science and technology, kansas state university, university of kansas, university of notre dame, and the university of oklahoma). the nmr system will play a key, connecting role in advancing fundamental knowledge in critical technology areas while promoting **\*\*diversity\*\*** and stem education at multiple educational levels. the acquired system is a commercial avance neo 400 mhz nmr spectrometer uniquely designed and equipped to acquire in-situ nmr spectra simultaneously from solid, liquid, and/or gas analytes at high-temperatures (up to 250 °c), high-pressures (up to 400 bar at 20 °c), or high-t,p conditions (up to 225 bar at 250 °c). the greater st. louis metropolitan region does not have an ssnmr facility with these capabilities. the spectrometer is designed for magic-angle spinning (mas) solid-state nmr (ssnmr) across a range of nmr-active species for conventional (ex-situ) nmr studies and for in-situ mas ssnmr capable of analyzing simultaneously gases, liquids, and solids under such high-t,p conditions. the spectrometer is equipped with a wide-bore magnet; mas pneumatic and variable temperature (vt) control with heater power booster units; vt-stack for high-t experiments; and high-t mas probe required for in-situ ssnmr experiments at high-t,p. access and administrative support will be provided through the nrf/jens lab with instrument management and oversight coordinated and supported by two advisory committees (a scientific advisory committee and an operations and management committee). the instrument will be available to internal and external academic users as

well as external corporate users through a web-based scheduling system. all users will pay hourly usage fees to support the operation and maintenance of the instrument. this broadly accessible ssnmr instrument, with its modern commercial console and high-t,p capabilities, will provide unprecedented opportunities to (1) familiarize students with this technology?important for their training and professional development, (2) advance the specific science and engineering research projects of user groups, and (3) facilitate shared expertise and catalyze new research partnerships and collaborations. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Supporting and Empowering Polar Early Career Scientists through the Polar Science Early Career Community Office

Awardee: University of Colorado at Boulder

Amount: \$884,771.00

Abstract: the university of colorado at boulder will provide support for the association of polar early career scientists (apecs) to accelerate national and international polar workforce development. this effort will bring the apecs leadership office to the usa for the first time and support the us-apecs office functions. the apecs office provides organizational support to the trans-disciplinary international membership of ~3800 early career polar scientists. the goal is to provide leadership development, training, networking and a voice to polar science students and postdocs. the three key activities are to: 1) establish an apecs office in the usa to provide infrastructure and expertise to the network, 2) build us early career polar science capacity through travel grants and support of the usapecs national committee, and 3) directly support impactful initiatives that support belonging, accessibility, justice, equity, **\*\*diversity\*\*** and inclusion (beajedi) in polar science. the cu boulder-based apecs office will leverage existing nsf investments to elevate the visibility of polar

science and connect early career scientists to international polar research efforts, such as large field and modelling campaigns, and efforts aimed at improving the inclusion of local and indigenous voices in arctic research. us polar research will benefit by connecting to this international and diverse pool of early career scientists, creating pathways to new collaborations and opportunities and being exposed to new voices. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: MIM: Elucidating the Rules of Cooperation and Resiliency in Microbial Communities through Stochastic Graph Grammars

Awardee: Carnegie Institution of Washington

Amount: \$874,451.00

Abstract: microbial communities in aquatic ecosystems are central to maintaining the resiliency of these important environments. these dense microbial populations are rich in species **\*\*diversity\*\*** and their genomes are dynamic because of processes such as gene duplication and horizontal gene transfer. despite extensive genomic flux due to these evolutionary processes, microbial communities cooperate and maintain stable interactions and are resilient to environmental perturbations. this project aims to develop a suite of computational tools for deciphering the rules that govern cooperation and resiliency in hot spring microbial mats, or biofilms, from yellowstone park. these well-studied environments are ideal for examining how critical environmental parameters such as temperature, light and nutrients influence the **\*\*diversity\*\***, abundance, and evolution of microbial populations. novel computational tools will be developed to identify rules that govern relevant biological processes. understanding how microbiomes evolve and adapt, especially with respect to the environment and to perturbations is crucial to understand many aspects of life. thus, the results obtained from this project will have a significant impact on biology, health, conservation efforts, and

animal and plant management. furthermore, this research will support the interdisciplinary development of a diverse cohort of phd and undergraduate students at rice university and carnegie institution for science located on the stanford university campus. this project will also support the development of a summer reu focused on bioinformatics, ecology, evolution, and microbiology, and will also include summer training opportunities for graduate students with collaborators at the pasteur institute in paris, france. this collaborative, multidisciplinary project presents an innovative plan for combining education and outreach activities to achieve real and lasting impact. all software developed will be made available on open-source code repositories. the overall goal of the project is to understand how microbiomes evolve and adapt, especially with respect to the environment and to perturbations. to meet these goals, the team of researchers will introduce methodological advances at the intersection of graph theory, formal languages, and machine learning to identify rules governing gene duplication and horizontal gene transfer from metagenomic sequencing data. in aim 1, the project will construct and correlate species abundance networks with genome exchange networks through genome assembly graphs. in aim 2, the project will produce a stochastic graph grammar framework for modeling network evolution over time, as well as unveil new rules with deep graph generators. in aim 3, genome-level simulations will be combined with the genomic events identified in aims 1 and 2 to assess the evolutionary benefits of these biological processes and their associated rates. the final project aim will focus on characterizing cooperation and resiliency through the study of graph grammars and network analysis techniques. the open-source computational methods developed across all four project aims will be evaluated on four distinct metagenomic datasets, including both environmental and host-associated microbiomes. finally, a wide variety of metagenomic datasets will be used to show generalizability of the computational approaches to host-associated microbiomes. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: MIM: Gut-inhabiting fungi influence structure and function of herptile microbiomes through horizontal gene transfer and novel metabolic function

Awardee: Middle Tennessee State University

Amount: \$870,000.00

Abstract: reptiles and amphibians are among the most threatened species on the planet, and an increasing number of their species must be managed in captive breeding programs. understanding the bio\*\*diversity\*\* and function of microbes that are present in the digestive tracts of reptiles and amphibians is critical for insight into their role in animal health. early research suggests that the filamentous fungus basidiobolus is an important member of reptile and amphibian gut microbiomes, and that this fungus influences what types of bacteria are present in the digestive tract. genomic sequencing of the basidiobolus fungus shows that genes have been transferred to the fungus from the gut bacteria. this transfer of genes between bacteria and fungi results in novel metabolism in the fungus that may play important roles in regulating the reptile/amphibian host's immune system, iron metabolism, and chemical communication with the gut bacteria. an interdisciplinary scientific approach will be used to understand the functional roles that specialized metabolites play in microbial interactions between fungi and bacteria in gut microbiomes of animals and also other natural microbiomes. outreach activities with zoos and the great smoky mountains national park will share information about reptile and amphibian gut microbiomes with the general public, and educational material will be provided to educators for inclusion in k-12 and university curricula. interdisciplinary training of students and postdoctoral researchers to prepare them for careers in research, education, and outreach is central to the project. this work will advance a new scientific understanding of the fundamental roles that specialized metabolites play in microbial interactions between fungi and bacteria in gut microbiomes. this will be accomplished through an interdisciplinary approach combining ecology and evolutionary biology, genomics and metagenomics, natural product chemistry, synthetic microbiome experiments, and controlled

amphibian feeding trials. preliminary data reveal that fungi in the genus basidiobolus are dominant members of the herptile microbiome, and that microbial community structure is shaped by the genetic **diversity** of basidiobolus, which has acquired specialized metabolism through hgt. integration of biological, molecular, genomic, metagenomic, and chemical resources in the proposed herptile system will allow for tests of the following hypotheses: h1: herptile microbiomes are characterized by unique fungal communities not found in other nonpathogenic, microbiome systems. h2: the bacterial assemblages of herptile microbiomes are structured by interactions with fungi. h3: hgt from co-occurring bacteria to herptile gut fungi allowed basidiobolus to acquire novel metabolic functions necessary to adapt to, and function in, the herptile microbiome. h4: fungal-bacterial interactions in herptile gi systems are regulated by metabolites that influence community structure and function. h5: the phenotype of the host-microbiome association is species/context dependent. this work will further refine the general model that the animal gastrointestinal environment promotes hgt between bacteria and fungi, and that this hgt selects for specialized metabolites that modulate the host immune system (cyclic peptides), and allow fungi to function in a reduced oxygen environment and compete in a bacterial rich microbial community (siderophores and surfactins). this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Integrating Artificial Intelligence with Smart Engineering and English Language Arts in Upper Elementary Education

Awardee: Tufts University

Amount: \$866,273.00

Abstract: this project will develop upper elementary school students' abilities to work with artificial intelligence (ai) in future careers. ai will be a critical tool for influencing and increasing productivity in the future of work. as such, it is increasingly important to introduce k-12 students to basic ai knowledge and skills, build familiarity with ai technologies, and train students to be competitive in the workforce. through this project, a team of robotics and education researchers at tufts university in massachusetts and maryville university in st. louis, mo will work with over 50 teachers in st. louis county to develop a research-informed educational ecosystem bringing ai concepts to upper elementary school students. this ecosystem will include a novel, low-cost, ai-enabled hardware toolset, including components such as sensors, actuators, and a microcontroller, for students to build smart systems, as well as support for teacher professional development. through after-school and summer programs, the project will engage over 1000 st. louis county students in constructing functional ai-enabled solutions to problems presented in fictional stories that the students read in english language arts and summer reading programs. the goal of the approach is to encourage transdisciplinary learning at the intersection of ai, engineering, and literacy. the education program testing will include 12 teachers and 500 students from the upper elementary target audience, with other participants in pilot testing across the k-12 grade band. the project aims to generate a new model for introducing vital ai concepts to elementary students that reduces barriers to integrating computational thinking into school curricula and provides tangible, trainable representations of ai for students to explore. researchers will investigate three primary research questions: 1) how does the

introduction of tangible artificial intelligence elements lead to changes in upper elementary students' understanding of artificial intelligence concepts and attitudes towards artificial intelligence? 2) how do different levels of complexity and variety of tangible artificial intelligence learning tools impact students' engagement and the **diversity** of their solutions and designs? 3) what are the potential benefits and challenges of introducing tangible artificial intelligence elements in integrated engineering and literacy activities? the project team will apply a design-based research (dbr) approach to jointly generate interdisciplinary education and learning sciences theory alongside iteratively designing and developing the toolset, professional development, and activities. the research will include interviews and surveys with ai professionals to develop and validate grade-appropriate measures of students' understanding of ai concepts and attitudes. the team will evaluate the research questions with a mixed-methods analytic approach, triangulating qualitative data from teacher interviews, lesson and professional development observations, student-made artifact analysis, and artifact-based student interviews with quantitative data from teacher and student surveys. the project's contribution will shift the artificial intelligence education paradigm towards a convergent curriculum and away from the status quo of coding and computing requiring separate instruction. the project findings will help inform the field about challenges specific to ai education in upper elementary grades. the deliverables from this project will include the ai animated inventions (ai2) hardware toolset, a teacher professional development model, a gallery of example activities and student work, and measures of the program's effectiveness, as well as the usability and utility of the tangible artificial intelligence elements for learning ai concepts. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Does responding to stressors prime greater resilience? Testing the long-term effects of challenges on behavior, physiology, epigenetic state, and fitness.

Awardee: Cornell University

Amount: \$863,173.00

Abstract: when faced with a major challenge ? severe weather, the attack of a predator, an injury ? organisms mount a coordinated physiological and behavioral stress response. this response can be vital for surviving and recovering from immediate threats. this project will test whether activating the stress response system has another overlooked benefit that operates over much longer time-scales: priming the system to respond better to future challenges. coordinated experiments will address fundamental questions about when and how environmental challenges prime greater resilience to future challenges, and examine whether those effects persist across generations. this study will also adapt and refine newly developed sensor technology that enables non-invasive monitoring of heart rate in free-living animals ? a tool that could yield considerable advances across fields. a more comprehensive understanding of the lingering impacts of challenges will also be valuable for other fields, including conservation and human health. additionally, the team will lead a career development program that combines a field research internship ? in which students participate in addressing the research objectives outlined in this proposal ? with a laboratory- and classroom-based skills development program for students from underrepresented groups who are interested in careers in stem fields. this opportunity is designed to foster interactions among students from a small liberal arts college and from a large research-intensive university. this project will test the hypothesis that transient challenges experienced in adulthood prime greater resilience or robustness to future challenges, defined as the ability to return to or maintain a stable state. research will use a long-term study population of tree swallows (*tachycineta bicolor*) in which large-scale behavioral and physiological data can be collected from free-living individuals. in the first year of study adult females will be exposed to either an ecologically relevant challenge or a simulated glucocorticoid stress response. in the following year(s) a **\*\*diversity\*\*** of phenotypic traits, and context-dependent performance and fitness, will be measured. this study design will enable comparison of the direct effects of exposure to a challenge with the effects of exposure to a

mediator of the response to that challenge. these experiments will also reveal whether the long-term effects of stressors on behavior, physiology, and fitness are mediated by glucocorticoids and by glucocorticoid-induced changes in dna methylation. this research will also test whether parental exposure history carries over to affect the phenotype and fitness of offspring produced in the year(s) after the challenge. by combining targeted experiments in a free-living population with integrative methods of behavioral, physiological, and epigenetic assessment this project will provide insights important for developing and revising conceptual models of stress and phenotypic plasticity. it will also broaden our understanding of the mechanisms of behavior, how organisms are shaped by their environments, and how sub-organismal responses contribute to organismal resilience and robustness. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Investigating chemosensory evolution in longhorned beetles using a comparative phylogenomic framework that integrates genomic, morphological, and biochemical data

Awardee: University of Memphis

Amount: \$856,023.00

Abstract: longhorned beetles are a highly diverse insect group with over 30,000 species. they feed on dead wood and also plants; in addition, they pollinate flowers. thus, they have an important positive ecological impact. however, sometimes they can be serious pests of living trees and timber. in spite of the ecological significance of the group and its rich **\*\*diversity\*\***, the evolutionary relationship of major groups of longhorned beetles remains a mystery. this research will reconstruct the evolution of the group by sequencing genomes of key species and comparing the differences. simultaneously, the project will explore why longhorned beetles have become so diverse and how this is linked to their namesake long ?horns,? or antennae. these horns are highly sensitive chemosensory organs that are used to smell and taste the environment. the latest techniques in microscopy, imaging, and genomics will be used to study longhorned beetle antennae, identify the genes that detect odors and tastes, and reconstruct how changes in these organs have contributed to the success of the group. this information will help assist efforts to control the longhorned beetles that are pests on trees and timber, while avoiding harm to species that have positive ecological impacts. moreover, the knowledge gained will help improve our understanding of chemosensation in other groups of arthropods that also include ecologically beneficial species and pests with major economic impacts. finally, this project will enable science mentoring, education, and outreach, through training undergraduate and graduate students and postdoctoral researchers, teaching k-12 students about insect bio**\*\*diversity\*\***, and widely sharing new data and educational materials. this project will produce the first comprehensive, large-scale phylogeny of longhorned beetles, which comprises a highly diverse radiation of primarily wood-feeding animals, in order to obtain a detailed

understanding of insect chemosensory biology and evolution. data from > 500 nuclear genes obtained from > 600 species via anchored hybrid enrichment sequencing will be considered, and extensive new data on the genetics and morphology of the group will be gathered. scanning electron microscopy will be used to compare the **diversity** and variation of antennal chemosensory organs across several longhorned beetle lineages. the research will yield antennal transcriptomes and annotated chemoreceptor and pheromone receptor gene repertoires, which will be used to conduct a comparative analysis of receptor chemistry. in this manner, the evolution of longhorned beetle chemical communication will be determined. the research will also help reveal how ecological distinctions among longhorned beetles are related to differences in chemosensory organs and chemoreceptor repertoires. this will enhance understanding of the evolution of different modes of longhorned beetle chemical communication and elucidate how the origins of these disparate modes may have influenced diversification. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: CAREER: Investigating the deep origin and evolution of the bird beak by synthesizing the fossil record and comparative embryology of archosaurian reptiles

Awardee: Yale University

Amount: \$856,022.00

Abstract: our planet teems with life in a vast array of shapes and sizes, interconnected in myriad ways by ecology and by descent. one way to understand how and why earth's bio**diversity** came to be is to trace the history of a great evolutionary radiation determine the key events that contributed to its success. among land vertebrates, birds stand out in terms of species number, engineering, and geographic spread. this project will explore both the history and the embryonic development of one of the signal innovations that underpins bird **diversity**: the beak. in doing so,

the project will discover the way in which the beak was built during evolution and the way in which it is assembled anew during the early existence of each individual bird. the avian beak is a ?key innovation,? a sort of technological advance that enabled subsequent success. it is a remarkably effective and versatile biological tool whose complex and efficient architecture has been modified for taking in food as disparate as nectar (hummingbirds) and flesh (birds of prey). the **\*\*diversity\*\*** of birds is, in many ways, a **\*\*diversity\*\*** of beaks. the beak was also integral to the evolution of bird flight: the first beaks, in the dinosaurian ancestors of birds, seem to have acted as ?surrogate hands? to replace the fingers fused and incorporated into the wing. this project will use fossils that document 300 million years of reptile evolution to determine the steps that led to the evolution of the bird beak. they will, in particular, seek to discover how pre-existing anatomical structures, especially the predatory jaws of ancient archosaurs were co-opted and rearranged to make the beak, and will search for signatures of the classic evolutionary (and engineering) phenomena of tradeoffs and co-dependencies (integration and modularity). the project also investigates how the embryonic beak is formed in modern birds and how its development differs from that of the reptilian snout ? in particular, whether comparisons of modern embryos with fossils and fossilized embryos can tell us about which parts of the bird beak form by late ?tweaking? of, or addition to, a fundamentally reptilian embryonic anatomy and which are truly ?new.? the grand narrative of the way in which birds, living dinosaurs, came to be so diverse and abundant in the modern world is naturally compelling, and the data to be generated are often striking and beautiful. the project will incorporate the findings of their work, including digital images and 3d prints of these data, into the courses they teach at yale and into kits and curricula designed for k-12 classrooms, with a focus on low-income urban schools. beyond exchange of materials and knowledge, the project's investigators will visit classrooms and will, moreover, conduct on-campus tours of research and collections facilities for k-12 students, many from underrepresented groups in stem, and their teachers, with the intention of building long-term relationships with schools, teachers and students. the project also will lead to the design of exhibits featuring the discoveries from this work in part of the newly renovated yale

peabody museum. finally, the project team will conduct a series of online and in-person public lectures and question-and-answer sessions throughout the duration of the project. the avian beak is a marvel of biological engineering and a key innovation that enabled the radiation of birds. this project will examine the morphological assembly of the beak from stem reptiles through to crown-clade birds and, simultaneously, the embryonic assembly of the beak as compared to that of the reptilian snout. in particular, the project will test the hypothesis of co-option followed by further novelty and constraint release in the origin of the avian head from the ancestral archosaurian head, then the origin of the neognath jaw apparatus from the ancestral avian kinetic system. this will be accomplished using a combination of 3d ct imaging of fossils and extant taxa, and reconstruction of soft tissue anatomy using phylogenetic bracketing. analyses of shape and transformation will be three-dimensional and quantitative. the project will further test hypotheses of integration and modularity of skeletal elements surrounding major soft tissue structures using a variety of methods, and in particular will elucidate constraint and tradeoffs resulting from spatial packing or competition for space. this will be accomplished by quantitatively analyzing evolutionary trajectories and developmental trajectories (in part reconstructed using high-fidelity confocal imaging of entire immunostained embryos). finally, the project will seek to unravel the relative contributions of the distinct ontogenetic or developmental processes of terminal addition and early transformation in the evolutionary origin of the avian skull, using an integrative approach that incorporates embryos, fossils, and fossil embryos. in particular, the project will include both evolutionary sequences of reconstructed ancestors (from fossil data) and ontogenetic sequences (fossil and extant) in combined analyses and will quantitatively assess the correspondence or non-correspondence of these sequences. ultimately, the project will present a comprehensive picture of the sequence of evolution and development leading to the distinctive avian condition, and will gain insight into the transformational phenomena and evolutionary dynamics in operation during its genesis. this project was jointly funded with the sedimentary geology and paleobiology program in the division of earth sciences. this award reflects nsf's statutory mission and has been deemed worthy of support

through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Tackling Functional Protein States at Atomic Detail by Integrating Weighted Ensemble Simulations with Magnetic Resonance Restraints

Awardee: University of Pittsburgh

Amount: \$855,989.00

Abstract: this project is designed to characterize the alternate structures of proteins?the workhorses of life whose functions in biology are determined by their structures. a major challenge to characterizing these so-called ?functional structures? is that these structures are often too diverse or fleeting to be captured by experimental techniques at the level of individual atoms. an unmet need is therefore a strategy that can determine the structures of functional protein structures at the atomic level and even more crucially, a strategy that can provide insights into how the functional structures interconvert. this project will develop a new software tool that can determine the functional structures of proteins, how the proteins move to convert from one structure to another, and the rates at which the structures interconvert. this tool combines the use of computer simulations with distances within proteins that are measured by experiments and will be made available through a popular, freely available westpa simulation software package. this interdisciplinary, collaborative project is providing a valuable training ground for graduate and undergraduate students participating in the research, and is supporting diverse educational and outreach activities, including biennial westpa software workshops to provide training to the scientific community in using the new tool for determining the functional structures of proteins. a new frontier in biophysics has been the structural characterization of protein functional states. proteins are the workhorses of life and their functions are determined by their structures. a major challenge to characterizing protein structures is that many proteins adopt not just a single structural state, but alternate states that are relevant to the biological functions of the proteins. due to the \*\*diversity\*\* and often transient nature of such

functional states, the determination of their structures at the atomic level has been elusive to experimental techniques. an unmet need is therefore a strategy that can generate atomically detailed structures of functional states, and even more crucially, a strategy that can provide detailed insight into the pathways for interconversion between the states and corresponding kinetics. a key advance of the project is the development of a general strategy that integrates sparse distance restraints from magnetic resonance experiments with rigorous simulations to provide atomic level structures and dynamics of functional protein states. this project will provide a new simulation tool that will be made available to the scientific community through the freely available westpa software. to further enhance the accessibility of the software, the westpa software will be integrated with the orion cloud-computing platform on amazon web services, the world's largest on-demand, cloud-computing facility. this project is funded by the molecular biophysics cluster in the division of molecular and cellular biosciences, with partial co-funding from the chemical measurement and imaging program in the division of chemistry. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: RUI: Will climate change lead to system shifts on tropical mountains?: the interplay of epiphyte losses on host tree function, microclimate, and hydrology

Awardee: Franklin and Marshall College

Amount: \$854,953.00

Abstract: tropical montane cloud forests (tmcfs) are important ecosystems to study and conserve due to their exceedingly high bio\*\*diversity\*\* as well as the critical roles these forests play in local and regional water cycling. deforestation in lowland regions and increases in global sea surface temperatures indirectly threaten these forests due to the lifting of the cloud base and an increase in drought conditions. epiphytes, i.e. plants that live on the surfaces of other plants, cover nearly all

tree surfaces in the tmcf and contribute substantially to ecosystem function due to their high capacity to capture and temporarily store water. unfortunately, these plants are the most vulnerable ecosystem components to projected changes in climate. a loss of epiphytes in the tmcf would lead to substantial bio\*\*diversity\*\* loss as well as a destabilization of water resources for human populations. this work aims to fill an important gap in the understanding of feedbacks among epiphytes and forest functions in the tmcf, and will provide important data for land-use and conservation workers as well as natural resource managers and governments in tropical montane regions concerned with long-term water security. a number of local and us-based workers and students will be trained in field and lab-based techniques and regular training events and exchanges will take place amongst all the participants. epiphyte gardens and accompanying curriculum will be created and placed in local schools to increase understanding and awareness of the connectivity between epiphytes and water cycling in the cloud forest.

tropical montane cloud forests (tmcfs) are under threat due to rapid changes in climate and in fact, recent work suggests that this ecosystem is predicted to contract substantially in the coming decades. this proposal addresses the question: how will a loss of the diverse and abundant epiphyte communities in the tmcf impact tree health, energy balance and hydrologic function? the investigators propose to conduct the first large-scale epiphyte removal experiment, in which trees in forest and pasture will be stripped of their entire epiphyte community. changes in crown-level microclimate (air temperature, relative humidity, leaf wetness, wind speed, solar radiation) as well as growth, water relations (water potential, sap flow, stomatal traits, carbon isotopes) and ecohydrological parameters (soil moisture, throughfall, stemflow) will be measured in and under the trees stripped of their epiphytes and compared with paired trees with intact epiphyte communities. direct field-based measurements will be coupled with remotely sensed parameters (ndvi, air temperature, leaf water content) using a high-precision drone outfitted with an integrated multispectral imaging system. a numerical model of epiphyte-host tree water relations will be developed and coupled to a land-surface hydrology model to scale up the field-based measurements and predict the effect of epiphyte loss on regional energy budgets and

canopy water cycling. field work will take place in five locations in the monteverde region of central costa rica. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Amount: \$854,953.00

Abstract: tropical montane cloud forests (tmcfs) are important ecosystems to study and conserve due to their exceedingly high bio\*\*diversity\*\* as well as the critical roles these forests play in local and regional water cycling. deforestation in lowland regions and increases in global sea surface temperatures indirectly threaten these forests due to the lifting of the cloud base and an increase in drought conditions. epiphytes, i.e. plants that live on the surfaces of other plants, cover nearly all tree surfaces in the tmcfs and contribute substantially to ecosystem function due to their high capacity to capture and temporarily store water. unfortunately, these plants are the most vulnerable ecosystem components to projected changes in climate. a loss of epiphytes in the tmcfs would lead to substantial bio\*\*diversity\*\* loss as well as a destabilization of water resources for human populations. this work aims to fill an important gap in the understanding of feedbacks among epiphytes and forest functions in the tmcfs, and will provide important data for land-use and conservation workers as well as natural resource managers and governments in tropical montane regions concerned with long-term water security. a number of local and us-based workers and students will be trained in field and lab-based techniques and regular training events and exchanges will take place amongst all the participants. epiphyte gardens and accompanying curriculum will be created and placed in local schools to increase understanding and awareness of the connectivity between epiphytes and water cycling in the cloud forest. tropical montane cloud forests (tmcfs)

are under threat due to rapid changes in climate and in fact, recent work suggests that this ecosystem is predicted to contract substantially in the coming decades. this proposal addresses the question: how will a loss of the diverse and abundant epiphyte communities in the tmcf impact tree health, energy balance and hydrologic function? the investigators propose to conduct the first large-scale epiphyte removal experiment, in which trees in forest and pasture will be stripped of their entire epiphyte community. changes in crown-level microclimate (air temperature, relative humidity, leaf wetness, wind speed, solar radiation) as well as growth, water relations (water potential, sap flow, stomatal traits, carbon isotopes) and ecohydrological parameters (soil moisture, throughfall, stemflow) will be measured in and under the trees stripped of their epiphytes and compared with paired trees with intact epiphyte communities. direct field-based measurements will be coupled with remotely sensed parameters (ndvi, air temperature, leaf water content) using a high-precision drone outfitted with an integrated multispectral imaging system. a numerical model of epiphyte-host tree water relations will be developed and coupled to a land-surface hydrology model to scale up the field-based measurements and predict the effect of epiphyte loss on regional energy budgets and canopy water cycling. field work will take place in five locations in the monteverde region of central costa rica. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Inclusively-designing sensory extensions for STEM inquiry learning

Awardee: University of Colorado at Boulder

Amount: \$850,000.00

Abstract: this project investigates innovative sensory extension device technologies to create learning materials that are accessible and enable diverse learners to use multiple modalities in science and mathematics learning. the new technologies will be designed, crafted, customized, and personalized by stem learners with diverse needs. humans think and communicate using multiple

sensory modalities, including sight, sound, gesture, movement, and touch. most science and mathematics learning materials convey information visually, with displays such as diagrams and simulations, resulting in learning experiences with limited sensory engagement. for many learners with visual or print-related disabilities, visual learning materials are inaccessible. even for others, these materials constrain learning opportunities. sensory extension incorporates materials and devices to enable new or enhanced perceptions of real or virtual environments. familiar sensory extension devices include eyeglasses (refractive lenses improve vision), and geiger counters (auditory perception of radioactive decay). in an inclusive co-design process, the project team will partner with diverse members of the learning community, together co-designing flexible, adaptive, and personalizable technologies, which enable new sensory experiences (e.g., sound, gesture, movement, and touch) to augment popular and widely used interactive simulation learning tools. the project team brings together experts in educational technologies at the university of colorado boulder (phet interactive simulations and the craft tech lab) and partner organizations serving youth with learning disabilities and visual impairments. this project will work to create new learning materials, practices and processes for inclusive design with youth, as well as theories and frameworks for the use of sensory extension technologies as learning resources. to accomplish this, the team will investigate (1) pedagogical and design practices within inclusive inquiry learning in stem learning settings; (2) the co-design and evolution of sensory extension devices; (3) learners' experiences of the impact of the inclusive design process on their own perceptions of self-efficacy and stem; and (4) the learning experience of youth with diverse needs using sensory extension devices for stem inquiry. the sensory extension devices are expected to enable new forms of collaboration among learners with differing sensory needs, and couple with existing educational technologies to expand their inclusive and accessible use and enrich the learning experience for all users. a rich corpus of data will be collected, tracking the trajectory of each design, including video and audio recordings of co-design sessions and the sensory extension devices in use, photographs of design artifacts and group activities, co-designer reflections and interviews, and self-efficacy

survey responses. through the inclusive co-design process, the project will work to advance foundational understanding of egalitarian processes of educational technology development, embrace sensory **\*\*diversity\*\***, and empower educationally marginalized learners through the creation, customization, and personalization of their own innovative learning tools. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Understanding microbial control of dissolved organic nitrogen (DON) in the ocean: New amino acid tracers for bacterial source and cycling of refractory DON

Awardee: University of California-Santa Cruz

Amount: \$849,702.00

Abstract: this award is funded in whole or in part under the american rescue plan act of 2021 (public law 117-2). one of the most mysterious components of the global nitrogen cycle is the vast amount of dissolved nitrogen-containing organic molecules (dissolved organic nitrogen, or ?don?) which exist in the ocean. the identities of these molecules are mostly unknown, but they are important in the ocean?s biological and geochemical cycles, because they persist for many thousands of years and in many cases these molecules are too complex for simple organisms at the base of the food web to use. this project will develop new chemical tools to understand this material, including stable isotopes, radioisotopes, and the chirality of amino acids. together, this new set of tracers will focus on the roles of marine bacteria as sources and creators of persistent dissolved organic nitrogen. the project will begin in the laboratory, where the team will first grow large cultures of ocean algae. natural ocean bacteria will then be added, and investigators will measure the proposed new tracers in dissolved nitrogen materials created. these data will reveal how the proposed tracers work: how and when they are produced, if they map to bacterial sources, and how bacterial degradation may affect them. the investigators will then conduct a series of field expeditions at contrasting sites on the california coast and in the central pacific ocean, isolating large amounts of natural dissolved organic nitrogen. the team will apply what has been learned in the lab together with the first ever radiocarbon measurements on individual tracer molecules. together these activities will open a new window into sources and cycling of the critical marine dissolved organic nitrogen material. the project will support the education, training, and career development of a graduate student, a postdoctoral researcher, and undergraduate students from underrepresented groups, who will be recruited to receive real hands-on laboratory and field experience. this project will develop three new amino acid?-based proxies for bacterial source and alteration of dissolved organic nitrogen: 1) compound-specific stable carbon isotope fingerprinting of essential amino acids, 2) a recently discovered suite of new d-amino acids found to be concentrated in radiocarbon-old, low molecular weight don material, and 3) individual amino acid radiocarbon values for key hypothesized tracer

amino acids. the investigators hypothesize that refractory ocean don is essentially completely microbial, however that it is also far more diverse than has previously been understood in terms of its sources, molecular composition, and especially cycling rates. in particular, the project will test the idea of completely different don origin, molecular composition, and cycling rates in high vs. low molecular weight don fractions throughout the water column. autotrophic and heterotrophic bacterial growth / degradation experiments will test assumptions about the sources and degradation- related changes to d/l and stable carbon isotope signatures. synoptically making these measurements together with individual amino acid radiocarbon values in high productivity coastal vs. oligotrophic pacific gyre don in both surface and deep ocean will allow understanding the **\*\*diversity\*\*** of don bacterial sources, degradation impacts, and n-specific cycling rates for the first time. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: CAREER: Physiological and Behavioral Determinants of Energy Use in Tropical Mammals

Awardee: University of Maine

Amount: \$829,716.00

Abstract: the ability to use energetically costly physiological processes to maintain body temperature at levels elevated above ambient temperature or endothermy, is a defining characteristic of mammals. the evolution of endothermy allowed mammals from warm, aseasonal climates to diversify and radiate into previously inhospitable environments as temperatures cooled. much of what is known about temperature regulation and energetics in mammals, however, has been derived from high latitude, northern hemisphere species whose evolutionary history has been shaped by large changes in temperature and extreme seasonality. to address this gap, the pi will leverage an existing collaboration, to examine the costs of living for nocturnal and diurnal small mammals in the tropical forests of malaysian borneo. the pi and her team will collect long term data on the body temperatures, metabolic rates, and life history characteristics of free-living small mammals. a novel, comprehensive database of mammalian physiological and life history traits, will be generated providing access to new, real data as a valuable learning experiences for the impact of climate on mammalian energetics. education activities will target university of maine undergraduate and graduate students, and k-12 students throughout maine. through first-hand experience with novel datasets from a unique environment, students will learn the importance of thermoregulatory physiology in understanding how animals respond to their environment. by increasing our knowledge of the functional energetics of tropical mammals not only can we understand the mechanisms underpinning current species distributions, but also help to improve our

predictions of organismal responses to changing global climates. the ultimate goal of this early career project is to build a framework to better understand the macrophysiology of mammals and better predict their potential responses to a warming world, by integrating physiology, ecology, and evolutionary biology. a high degree of bio\*\*diversity\*\*, endemism, and an almost complete lack of basic data physiological data available for small mammals from the indo-malayan zoogeographic region, creates an ideal arena in which to stage a long-term project of integrated research and education. the pi and her team seek to answer the following questions: 1) do nocturnal small mammals have more flexible body temperatures than their diurnal counterparts; 2) does it cost more (in terms of energy and water) to be nocturnal or diurnal in a consistently hot and humid environment and, 3) how will these differences affect their ability to respond to climate change. through answering these questions, the research will generate novel datasets on the physiology and energetics of six or more species of tropical small mammals. when combined with existing data from temperate mammals, these data will be used test hypotheses on the evolution of homeothermy, and the role of energetics in the life history of mammals. ultimately, the research will generate a comprehensive framework for using mammalian thermoregulatory phenotypes in modeling mammalian responses to climate. the research aims of this proposal will be integrated with education activities that will target undergraduate and graduate students at the university of maine and k-12 students throughout the state. through first-hand experience with novel datasets from a unique environments, will learn demonstrate the importance of thermoregulatory physiology in understanding how animals respond to their environment, while providing research and outreach opportunities for junior scientists and the general public. together the knowledge of the functional energetics of tropical mammals will advance the understanding of mechanisms controlling current species distributions, but also help to improve our predictions of organismal responses to changing global climates. this career proposal was supported by the integrative ecological physiology program within the division of integrative organismal systems within the directorate for biological sciences and the established program to stimulate competitive research (epscor) program within the

office of integrative activities. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: HCC: Medium: Designing Human-Centered Environments for Enhancing Diversity in Open Source

Awardee: Carnegie-Mellon University

Amount: \$820,000.00

Abstract: to increase inclusion and enhance **\*\*diversity\*\*** at all levels of participation, this research will investigate gender-based barriers to involvement in open source software. surveys show that the representation of women in open source software is only about 5%, even worse than the technical workforce overall. previous research on gender in the computing profession has identified lack of self-efficacy and mentorship support as key barriers to participation and retention for women and underrepresented individuals. this project will investigate how these barriers influence participation in open source software development communities. it will identify and disseminate actions project owners and contributors can take to enhance participation from underrepresented groups. this research will create tools and conduct workshops to enhance participation from underrepresented members. since participation in open source is increasingly important for obtaining employment in technical fields, this research has the potential to significantly enhance workforce development. finding ways to make open source more welcoming to all genders could nearly double the available technical workforce, with major benefits both to industry, where talent is in short supply, and to society, by enhancing the nation's ability to create software-intensive products and services. this research will enhance **\*\*diversity\*\*** in open source by first performing a series of mixed-methods studies of practice, consisting of interviews, a large-scale survey, and archival analyses to understand: (a) how participation experiences vary based on subjects' genders; and (b) why they

leave or do not join open source software projects. based on these studies, the research team will design, deploy, and evaluate interventions that enhance self-efficacy and facilitate new forms of mentoring in open source environments. the following specific research contributions are expected: (1) deeper knowledge about the causes of low participation by women in open source software development and open collaborative environments; (2) an understanding of how automation and visualization can support self-efficacy and mentorship for underrepresented contributors in open collaboration environments; and (3) guidelines for the design of inclusive collaboration environments. more generally, this research is expected to yield new knowledge about how to enhance human performance through the design of inclusive, open environments in software engineering and even more broadly, for computer-supported collaboration. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: CAREER: Development of Unmanned Ground Vehicles for Assessing the Health of Secluded Ecosystems (ECHO)

Awardee: Woods Hole Oceanographic Institution

Amount: \$813,964.00

Abstract: part i: non-technical description: understanding human-induced changes on bio\*\*diversity\*\* is one of the most important scientific challenges we face today. this is especially true for marine environments that are home to much of the world's biomass and bio\*\*diversity\*\*. a particularly effective approach to investigate the effects of climate change on marine ecosystems is to monitor top-predator populations such as seabirds or marine mammals. the food web in the southern ocean is relatively small and involves few species, therefore climate-induced variations at the prey species level directly affect the predator species level. for example, seabirds, like penguins, are ideal to detect and study these ecosystem changes. this study combines traditional methods to study emperor penguin population dynamics with the use of an autonomous vehicle to conduct the population dynamic measurements with less impact and higher accuracy. this project leverages an existing long-term emperor penguin observatory at the atka bay colony which hosts penguins living in the weddell sea and the atlantic sector of the southern ocean. the study will kickstart the collection of a multi-decadal data set in an area of the southern ocean that has been understudied. it will fill important gaps in ecological knowledge on the state of the emperor penguin and its adaptive capabilities within a changing world. finally, the project supports nsf goals of training new generations of scientists through collaborative training of undergraduate students and the creation of a new class on robotics for ecosystem study. emperor penguins are an iconic species that few people will ever see in the wild. through the technology developed in this proposal, the public can be immersed in real-time into the life of an emperor penguin colony. public outreach will be achieved by showcasing real-time video and audio footage of emperor penguins from the field as social media science and engineering-themed educational materials. part ii: technical description:

polar ecosystems currently experience significant impacts due to global changes. measurable negative effects on polar wildlife have already occurred, such as population decreases of numerous seabird species, including the complete loss of colonies of one of the most emblematic species of the antarctic, the emperor

penguin. these existing impacts on polar species are alarming, especially because many polar species still remain poorly studied due to technical and logistical challenges imposed by the harsh environment and extreme remoteness. developing technologies and tools for monitoring such wildlife populations is, therefore, a matter of urgency. this project aims to help close major knowledge gaps about the emperor penguin, in particular about their adaptive capability to a changing environment, by the development of next-generation tools to remotely study entire colonies. specifically, the main goal of this project is to implement and test an autonomous unmanned ground vehicle equipped with radio-frequency identification (rfid) antennas and wireless mesh communication data-loggers to: 1) identify rfid-tagged emperor penguins during breeding to studying population dynamics without human presence; and 2) receive global positioning system-time domain reflectometry (gps-tdr) datasets from very high frequency vhf-gps-tdr data-loggers without human presence to study animal behavior and distribution at sea. the autonomous vehicles navigation through the colony will be aided by an existing remote penguin observatory (spot). properly implemented, this technology can be used to study of the life history of individual penguins, and therefore gather data for behavioral and population dynamic studies. the new data will contribute to intelligent establishment of marine protected areas in antarctica. the education objectives of this career project are designed to increase the interest in a stem education for the next generation of scientists by combining the charisma of the emperor penguin with robotics research. within this project, a new class on ecosystem robotics will be developed and taught, robotics boot-camps will allow undergraduate students to remotely participate in antarctic field trips, and an annual curriculum will be developed that allows k-12 students to follow the life of the emperor penguin during the breeding cycle, powered by real-time data obtained using the unmanned ground vehicle as well as the existing emperor penguin observatory. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Core Support for Future Earth International Global Change Research

Awardee: University of Colorado at Boulder

Amount: \$804,895.00

Abstract: this project supports the us secretariat of future earth. future earth harnesses the insights and capacity of the global scientific community to address global problems, like a warming and increasingly unstable climate, and a rapid loss of bio**diversity** and ecosystem services. the future earth effort is based on the recognition that modern global change challenges require coordinated research efforts bringing together the world's best researchers in the natural, social, behavioral, and engineering sciences, and connecting these researchers with the needs and capacities embedded within a wide range of stakeholder institutions and communities. the secretariat leads and co-leads

core functions that include research enabling, networks and capacity, information technology, and communications. In addition, the US Global Hub leads the evolution and growth of Future Earth's global efforts and directs many of Future Earth's core global initiatives, including a flagship capacity building program, communications products, and collaborative data-platforms. Future Earth provides a critical service to the science community by advancing global change science in the US and around the world, and by supporting the full range of research modalities from fundamental disciplinary research to transdisciplinary research. By connecting research across geography and discipline, the project supports the emergence of novel, integrative scientific ideas. By elevating the spread and impact of scientific results and connecting these results with constituencies in business, government, and civil society, Future Earth's work supports decision making around the world. It also connects US researchers with a vast and rapidly growing network of leading international scholars in global change research and provides direct access to new knowledge and initiatives. This work includes a broad range of communication capacities in the US and around the world, like the establishment of the Sustainability Research and Innovation Congress, the first global convening that brings the global change research and innovation communities together, on an annual basis. The Future Earth US Global Hub has also established partnerships to build and diversify the next generation of global change researchers through an internship program. This award reflects NSF's statutory mission and has been deemed worthy of support through evaluation using the Foundation's intellectual merit and broader impacts review criteria.

Title: IntBIO Collaborative Research: An integrative approach for projecting insect responses to a rapidly changing climate

Awardee: Georgetown University

Amount: \$803,034.00

Abstract: Projecting species' responses to climate change at continental scales is a current "grand

challenge? of ecological research. insects are sensitive indicators of both climate and land-use change and recent studies indicate widespread declines in many geographic regions. to predict changes across entire ranges, a variety of species distribution models have been developed, but rarely account for regional variability, ecological interactions or a species? potential to adapt to changing conditions. this project spans multiple institutions situated in the united states? southwest, polar north, and temperate eastern regions. a series of physiological experiments will be implemented for five widespread butterfly species with populations sourced from different biomes within each of their ranges. caterpillars will be subjected to a range of conditions mimicking past, current and future climates. their development rate, survivorship, immune response, and genetic structure and gene expression (which genes are actively coding for proteins) will be measured and used to build models that predict distributional shifts. data collected by community (?citizen?) scientists will be used to validate the models. this project requires substantial cross-disciplinary collaboration, and a central goal is to recruit diverse trainees at the graduate and undergraduate levels and train them in the ?science of team science?. project trainees will develop independent research ideas that align with and expand the project?s scope and travel between and work at collaborating institutions as an inter-lab exchange to learn new techniques and be exposed to different research philosophies. finally, the project has significant management implications for insect bio\*\*diversity\*\* conservation.

projecting responses to climate change at continent scales is a current ?grand challenge? of ecological research. insects are the most diverse and ecologically important terrestrial animal taxon and are strongly affected by climate change. to predict changes, species distribution models (sdms) have been widely implemented across many taxa. sdms, however, rarely account for ecological interactions, plasticity or evolutionary adaptive potential owing to the extensive physiological and ecological data required to parameterize such models. the biology of lepidoptera, particularly butterflies, is extremely well observed, thus it is logistically feasible to build upon past knowledge and collect additional data that enables mechanisms to be more seamlessly integrated into sdms. multiple populations for each species will be sourced from

different biomes across its range. caterpillars will be reared in common gardens under a range of temperature conditions mimicking past, current and future climates. their development rate, survivorship, immune response, genetic structure and gene expression will be measured and used to build models that predict future distributions. distribution data collected by community (?citizen?) scientists will be used to validate and improve models and allow robust estimates of uncertainty. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Noyce Scholar Retention in Racially and Culturally Non-dominant Communities: Studying the Relationship between Partnerships and Persistence in the Teaching Profession

Awardee: American University

Amount: \$800,000.00

Abstract: this project aims to serve the national need to increase the **\*\*diversity\*\*** of the stem teacher workforce by understanding the factors that contribute to stem teacher retention. this project investigates how the quality of research-practice partnerships that support noyce scholars influences persistence and retention of both teachers of color and white teachers in high-need schools serving racially and culturally non-dominant communities. the research team aims to investigate how the three noyce program components - teacher preparation, induction/mentoring, professional development - and the collaborative nature of those teacher development components (i.e., partnerships) affect noyce scholars? persistence in high-need schools serving racially and culturally non-dominant communities. this project includes the study of six noyce projects at bowie state university, george washington university, mercy college, montgomery college, the university of maryland, and american university. the principal investigator (pi) team seeks to identify differences, and the extent to which the three components contribute to such differences, in persistence and retention in teaching between scholars of color and white scholars. the study is

framed through the lens of determining how the scholars have experienced race, racism, and power within the three noyce program components described above and how these experiences influenced their retention in the six noyce projects and in teaching. in particular, the pi team seeks to develop deeper understanding of how the experiences of serving in racially and culturally non-dominant communities interact with the scholars? individual teacher preparation, induction, and professional development experiences at each institution. the research design also examines in what ways, if at all, the partnerships created to support the three noyce program components have influenced the persistence and retention of noyce scholars of color. such partnerships include those between stem departments and schools/colleges of education, and between noyce teacher preparation programs and high-need school districts, and other partners. finally, the research team also asks: what is the quality of the partnerships, how are the quality of the partnerships related to the three noyce program components, and how the partnership itself influences teacher persistence and retention in schools serving racially and culturally nondominant communities? the research team will use a mixed methods approach that includes surveys of scholars, and noyce program and partner program faculty and staff. structured, semi-structured, and empathy interviews with selected members of those groups will be conducted. in addition, a multi-case comparison of at least two teacher preparation programs with robust partnership components will occur. the results of this study are intended to provide evidence-based insights into the influence partnerships have on stem teacher persistence and retention and how to improve partnerships for the benefit of all stakeholders. results will be disseminated to practitioner and research audiences including stem education programs. this track 4: noyce research project is supported through the robert noyce teacher scholarship program (noyce). the noyce program supports talented stem undergraduate majors and professionals to become effective k-12 stem teachers and experienced, exemplary k-12 teachers to become stem master teachers in high-need school districts. it also supports research on the persistence, retention, and effectiveness of k-12 stem teachers in high-need school districts. this award reflects nsf's statutory mission and has been deemed worthy of support through

evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: FW-HTF-R: Collaborative Research: Worker-AI Teaming to Enable ADHD Workforce Participation in the Construction Industry of Future

Awardee: Purdue University

Amount: \$800,000.00

Abstract: while people with neuro\*\*diversity\*\* have been marginalized in the construction workplace due to potentially higher risks of injuries, their unique talents could be leveraged using an ecosystem of co-bots driven by artificial intelligence (ai). for humans and machines to become true teammates?and correlatively, for technology to extend occupational opportunities to people with such neuro\*\*diversity\*\*?intelligent machines must assess, adapt, and respond to both workers and their environment. such agility requires a reciprocal teaming capability wherein workers can engage their ai counterparts as more than tools, and ai systems can collaborate with workers seamlessly by predicting their behaviors. to extend future occupational opportunities for people with neuro\*\*diversity\*\*, this project builds an ai-driven learning platform to enable distribution of ai teammates in construction workplaces to support employment opportunities and safety outcomes for construction workers with varying abilities. this study also investigates the intended work scenarios of worker-ai teaming, the unintended consequences of ai-teaming for workers, and the well-being of society. considering that 4.2% of workers are diagnosed with attention-deficit/hyperactivity disorder (adhd)?a disorder that is associated with more than 120 million lost workdays in the usa each year, equating to a human capital value of \$19.5 billion?this project?s efforts to enable diverse workforce participation in the construction industry will have positive social and economic impacts. additionally, this project will educate a new generation of leaders in worker-ai teaming and will create partnerships between academia and industry. to lay the necessary foundations for building this human-ai teaming workspace for construction workers with neuro\*\*diversity\*\*, this proof-of-concept project will translate non?invasive biomechanical and neuro-psychophysiological responses into information a personalized ai-based training systems can assess, model, and leverage to predict workers? behaviors for improved worker?machine teaming without cultivating technological over-reliance or threats to privacy. in this project, a multidisciplinary team of researchers integrates expertise in civil engineering, computer science, cognitive and behavioral psychology, industrial engineering, and public policy and economics to address fundamental questions regarding the risk

taking behavior and cognitive processes of workers with adhd, barriers to adopting ai and wearable technologies, and the socioeconomic impacts of improved access to construction jobs for adhd-diagnosed workers, especially in the context of interdependent human-ai partnerships. as this project?s global paradigm moves toward deeper human-machine teaming, the knowledge gained through this project advances the science and technology that influences diverse workforce development, education, and positive work outcomes for workers and society at large. by demonstrating the effectiveness of this ai-driven platform, this project illustrates how human-machine teams can progress on job sites and within communities across all sectors to augment human cognitive capabilities. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: CNS Core: Medium: Systems Support for Federated Learning

Awardee: Regents of the University of Michigan - Ann Arbor

Amount: \$800,000.00

Abstract: traditional approaches toward applying machine learning techniques to end-user data often require copying all data to the cloud. this is not only expensive but faces data privacy risks as well. by analyzing data on the device where it is generated, federated learning aims to mitigate both cost and privacy concerns of centralized machine learning without sacrificing its benefits. this collaborative project brings together investigators from two institutions to develop building blocks for practical federated learning by addressing challenges arising from the **\*\*diversity\*\*** of user devices and the heterogeneity of data distributions in those devices. the project takes a three-pronged approach: (1) enable performance improvements for machine learning developers (e.g., judicious participant selection instead of randomly selecting participants); (2) provide efficiency improvements for service providers (e.g., redundancy elimination for data transfers); (3) enable end-users to

control their data privacy (e.g., akin to app permissions in android) without sacrificing device usability. two core principles underpin these solutions: multi-tenancy both in the cloud and on individual devices; and maintaining theoretical correctness, convergence characteristics, and privacy/security guarantees of federated learning algorithms. widespread adoption of practical federated learning can fundamentally change how we gather insights from end-user data and how users value data privacy, because users may not have to sacrifice privacy for convenience in many cases. this, in turn, can force large corporations to rethink their data collection and usage practices, and influence policy makers to consider stricter privacy regulations. all software from this project will be open source. through outreach and new educational materials, this project will pioneer the training of privacy-aware systems builders. this collaborative project will produce software artifacts, experimental harnesses, benchmarks, and results of running those benchmarks and artifacts. these materials will be available for public use under permissive open-source licenses at multiple locations, including <https://github.com/symbioticlab>. they will be retained for at least three years after the completion of the project. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Howard-Columbia Partnership for Research and Education in Superatomic and 2D Materials (PRES2M)

Awardee: Howard University

Amount: \$800,000.00

Abstract: this award is funded in whole or in part under the american rescue plan act of 2021 (public law 117-2). howard university is a private, federally chartered historically black university in washington, dc with more than 10,000 students pursuing 120 areas of study; and currently classified as a high research activity institution. materials science and engineering (mse) related research at

howard focuses primarily on quantum materials, optics and photonics and quantum technologies (computing, communications, and sensing). the research focus of this partnership for research and education in materials (prem) with columbia university materials research science and engineering center (mrsec) is on interaction of light with matter for new optical and electrical devices for the quantum information age. this collaboration, namely partnership for research and education in superatomic and 2d materials (pres2m), is to establish the framework needed to pursue new prem-pathway for faculty and students at howard university in mse. in particular, the following is envisioned: an integrated research and education program that increases participation of undergraduate students in mse-related research mentored by graduate student trainees and teacher-scholar postdoctoral associates in mse to strengthen existing **\*\*diversity\*\*** efforts at columbia and provide a foundation for the mse degree-granting program at howard. the prem pathway focuses on matriculation of undergraduate students in mse-related disciplines to allow for significant growth in the total number of black students that attain degrees. furthermore, the collaboration between howard and columbia university mrsec is aimed at impacting current **\*\*diversity\*\*** efforts at columbia with respect to k-12 outreach, undergraduate student research opportunities, and graduate student admissions. the primary research goal of pres2m is a better understanding of the quantum phenomena within functional materials, such as, 2d materials and superatomic molecules through a cyclic interplay between materials synthesis, processing, analysis, and theory. the research is aimed at altering material properties to manipulate light-matter interaction including new experimental techniques for thermal tunability of ultra-strong coupling in 2d nanopatterned films and plasmon-enhanced conductance. this research builds on the materials science of 2d and superatomic materials and applications of quantum phenomena, currently pursued at the columbia university mrsec. the goal of this partnership is to fundamentally impact condensed matter physics and materials science and engineering. through the mrsec, howard faculty and students have access to infrastructure, new materials, and expertise in quantum materials research. with the pres2m, there is an expanded collaboration between both institutions

and additional opportunities for co-mentorship of students and postdoctoral associates, joint projects and publications as well as student/faculty exchanges. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: CAREER: Unraveling post-invasion dynamics of the amphibian-killing fungus via rapid genetic diversity assessments of both hosts and pathogens

Awardee: Texas State University - San Marcos

Amount: \$797,737.00

Abstract: in wildlife, prominent examples of mycoses (diseases caused by fungi) include white-nose syndrome and the recent spread and emergence of snake fungal disease, but no other fungal pathogens have been more destructive to wildlife than the amphibian chytrids (genus *batrachochytrium*). chytrids are essentially ubiquitous in the environment, yet they are relatively understudied. amphibian chytrids continue to cause population declines and species extinctions globally. unfortunately, the most severe amphibian declines have occurred in neotropical forests, which are also threatened by deforestation. for tropical amphibians, the threat of disease, coupled with habitat loss, requires rapid measurements of host **\*\*diversity\*\*** at the population scale to unravel complex disease dynamics. studies of disease dynamics can benefit from the development and use of genetic methods that can be applied in real-time and in the field. by leveraging emerging portable technology to measure genetic **\*\*diversity\*\***, this project will gather data for both hosts and pathogens to test hypotheses regarding the specificity of their interactions, determine which hosts drive spread or act as reservoirs, and contribute to amphibian conservation. the research and educational goals of the project will be implemented at a hispanic-serving institution and led by a first-generation, mexican-american principal investigator (pi), and thus, will increase the participation of underrepresented groups in stem at all levels. additionally, the project will serve to train the next

generation of students and international biologists in the application of emerging genetic methodologies to address common challenges in disease ecology, which can be extrapolated to other systems where diverse hosts drive pathogen spread. the overarching goal of this project is to elucidate fungal pathogen **diversity** and post-invasion pathogen dynamics in equatorial forests and their understudied canopies by identifying which hosts have driven the transition from an epizootic to an enzootic pathogen. the aims of this research are to: 1) perform real-time strain detection using portable quantitative pcr instruments and dna sequencing using portable nanopore sequencers to reveal pathogen **diversity** and geographic distribution along an equatorial transect, 2) parse amphibian genetic identity in a hyper-diverse assemblage to allow host-specific estimates of pathogen/strain prevalence, and 3) use cophylogenetic analyses to test for the influence of host **diversity** on pathogen invasions. the pi is uniquely positioned to achieve these research goals while providing experiential learning opportunities to underrepresented students in stem at the undergraduate and graduate level. this project is being jointly funded by the systematics and bio**diversity** cluster and the evolutionary processes cluster in the division of environmental biology at the national science foundation. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: RUI: Role of the Endoplasmic Reticulum in mediating cell fate

Awardee: San Francisco State University

Amount: \$796,064.00

Abstract: a major step during development in multicellular life is the generation of cell \*\*diversity\*\*. specifically, the task of cells adopting a specific shape and function is essential towards development of the adult body plan and formation of tissues in multicellular organisms. this is a highly conserved process among multicellular creatures and involves an unequal or asymmetric partitioning of factors during cell division to allow cells to adopt different fates (e.g. to become neurons or become skin). there has been significant progress in understanding the distribution of these factors; however, the regulation of movement and the selection of these determinants and how they are passed to daughter cells is still poorly understood. the principal investigator (pi) has formed a model in which cell fate-determining factors are organized and distributed during cell division by the endoplasmic reticulum (er), the largest compartment in the cell involved in protein folding and distribution. the objectives of this project are to define a pathway for the transport and correct establishment of cell-fate determinants during cell division, and to characterize the role of the er in the generation of cell \*\*diversity\*\*. in addition, the pi will provide opportunities to engage a diverse student population and promote peer mentorship, thereby broadening participating in science. the outcomes of the project will help close a gap of knowledge regarding how cell fate is determined, and to provide a broader understanding for the generation of cell \*\*diversity\*\* during development. the generation of cell \*\*diversity\*\* is a highly conserved mechanism and involves the

asymmetric partitioning of factors during cell division. over the past 30 years, several cell fate determinants have been identified, including cell fate determinants that are partitioned apically or basally during mitosis leading to the daughter cells adopting different cell fates. despite the considerable knowledge regarding the factors involved in cell fate selection, there is little known regarding the transport, localization, and organization of these cell fate determinants along the division plane during mitosis. preliminary data from the pi's laboratory identified the highly conserved endoplasmic reticulum (er) integral membrane protein, jagunal (jagn) as being partitioned asymmetrically in pro-neural cells during drosophila melanogaster embryogenesis. the pi's central hypothesis is that the jagn-mediated asymmetric division of the er acts as a scaffold for organization and transport of transcriptional machinery involving the basal cell fate determinants towards the diversification of cell types in the central nervous system. the pi will test this hypothesis in vivo by examining neuroblast division in the drosophila melanogaster larval brain by means of super-resolution confocal microscopy, and determine which cell fate outcomes are dependent on jagn. the pi's work will deepen our understanding of cell fate selection and outline the role of the er in the generation of cell \*\*diversity\*\*. this research is funded by the cellular dynamics and function cluster in the division of molecular and cellular biosciences in the directorate of biological sciences.

Title: IUCRC Phase II: North Dakota State University: Center for Bioplastics and Biocomposites [CB2]

Awardee: North Dakota State University Fargo

Amount: \$793,875.00

Abstract: the center for bioplastics and biocomposites (cb2) at iowa state university (isu), university of georgia (uga), washington state university (wsu), and north dakota state university (ndsu) seeks

to develop and build on an industry/university cooperative research center (i/ucrc) that focuses on bioplastics and biocomposites. the mission of cb2 is to develop fundamental knowledge related to bioplastics and biocomposites, to disseminate research-based findings to industry to promote sustainability, and to educate future scientists and engineers. as such, there is an expressed industrial interest in leveraging research efforts to accelerate systematic development of standardized material and processing data for these novel plastics and composites. the center focusses on the development of jobs in the area of sustainable manufacturing and the conversion of agricultural and woody crops to bio-based materials that contribute to job creation in the united states. the center also strives to support education and **\*\*diversity\*\*** through engagement of undergraduate and graduate students in research on sustainable materials. the goal of cb2 is to improve the basic knowledge of synthesis, processing, properties, and compounding of bioplastic and biocomposite materials, to develop reliable materials characteristics data for industrial partners, and to support large-scale industrial implementation of renewable materials. the vision of the center is to develop knowledge that will facilitate the production of an array of high-value products, including plastics, coatings, adhesives, and composites, from renewable feedstocks. the materials are compatible with current industrial manufacturing systems and promote rural development as well as national growth. the goals of the phase ii are fourfold: 1) expand the knowledge and develop the science for recycling and end of life treatment of sustainable materials, in particular as they are mixed with petrochemical plastics; 2) expand membership by engaging new companies that have expressed a need for recycling and end of life treatment; 3) develop fundamental knowledge on sustainable materials; 4) prepare students to join the workforce equipped with the knowledge and skills required by industry. the team of researchers includes experts in the fields of polymer processing, polymer chemistry, materials science, and crop utilization. wsu's research focuses on utilizing industry-relevant technology platforms to develop bio-based composites, coatings and adhesives, and polymers for various industry applications, as well as to recycle bio-based composite materials. ndsu's research focuses on use of biobased fibers, novel monomers derived from

biomass, biobased polymers with applications in coatings, adhesives and composites, and materials for packaging applications. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Excellence in Research: Statistical Network Modeling and Inference for Complex Data

Awardee: North Carolina Agricultural & Technical State University

Amount: \$783,432.00

Abstract: estimation and inference of network structure have wide applications in many scientific fields such as genomics and finance. however, the abundance of complex data presents a great demand for new statistical learning methods in network analysis. a main goal of this project is to develop a set of novel methodological and theoretical tools to identify change points and infer structural changes for high-dimensional networks. success of this project can have significant

impacts on biomedical sciences and finance. data applications to the alzheimer's disease and portfolio risk monitoring will help to offer new insights. the team will develop computational packages to facilitate the application and dissemination of the proposed methods to academia and industry. furthermore, the research will be closely integrated with education, through joint supervision of students and joint development of courses from two institutions. underrepresented minority students will be recruited and involved in the project. the collaborative project will provide an opportunity for students and faculty in an hbcu institution to gain access to cutting-edge research and educational resources, and help increase the **\*\*diversity\*\*** of the next generation of data scientists. the research of this project has two main directions. the first one focuses on change point analysis for heterogenous data. to detect possible change points of a high-dimensional graph, a threshold variable and a threshold parameter are introduced while considering all nodes simultaneously to construct a highly effective algorithm. to simultaneously identify change points in a high-dimensional linear model, an innovative method to test homogeneity of the corresponding regression coefficients across different segments is considered. for the second direction, a nonparametric testing method is developed to compare correlation/covariance matrices. the team plans to investigate theoretical properties of the proposed methods and apply the methods to genomics and finance. this project can provide unique contributions to the statistical learning and big data literature. in addition, the knowledge gained from the proposed research can be valuable for handling other complex high dimensional problems in statistics and machine learning. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: CCRI: New: Medium: A Development and Experimental Environment for Privacy-preserving and Secure (DEEPSECURE) Machine Learning

Awardee: Old Dominion University Research Foundation

Amount: \$780,000.00

Abstract: while machine learning (ml) is embraced as an important tool for various science, engineering, medical, finance, and homeland security applications, it is becoming an increasingly attractive target for cybercriminals. deepsecure is a first-of-its-kind development and experimental platform to support secure and privacy-preserving ml research. with its novel modular design integrated with fully customizable function blocks and sample modules, deepsecure is a game-changing tool to effectively support research in this emerging field by enabling fast design, prototyping, evaluation, and re-innovation of trust-worthy ml applications. it enables a variety of compelling new research projects that focus on ml security and privacy, leading to breakthroughs to protect ml systems and accelerating their development and widening their adoption. it will contribute significantly to the protection of the future cyber and physical world and safeguard human society. deepsecure receives strong community support from over 20 key stakeholders across the country. the project includes significant efforts for fostering and sustaining an ml security and privacy research community, including monthly virtual open forums to provide a regular update to and seek feedback from the community, quarterly advisory board meetings, annual symposiums, and a training workshop series. the project includes specific measures and plans for inspiring the participation of underrepresented groups and infusing **\*\*diversity\*\*** and inclusion in all deepsecure events and activities. the project output includes an open-source and easy-to-use learning platform for curriculum development and workforce training. to support building a sustainable workforce development pipeline, the project team participates in the existing annual gencyber summer camps for k-12 students and a cyber saturday series to introduce cybersecurity and ai career paths and educational resources to k-12 school counselors, teachers, students, and parents. recent development in privacy-preserving and secure ml draws expertise from both ml and security/privacy to tackle the multi-faceted problem. however, the research community is facing fundamental challenges in this emerging area due to its interdisciplinary nature. on the one hand, although deep learning frameworks such as pytorch and tensorflow have been made widely available, a critical

hurdle faced by ml researchers is the steep learning curve to effectively use security techniques and libraries to tackle ml security and privacy problems. on the other hand, while the security community has developed highly efficient cryptographic libraries, it remains nontrivial to integrate them into deep learning models to achieve a computation efficiency suited for practical applications. the overarching goal of the project is to close the gap by developing deepsecure, which integrates a spectrum of essential functions and building blocks that are ready-to-use to flatten the learning curve for researchers coming from both ml and security/privacy communities. at the same time, deepsecure is fully customizable and scalable, enabling deep and fundamental research toward privacy-preserving and secure ml. to meet the overarching goal, specific project objectives include: (1) acquiring a scalable and re-configurable compute environment based on the latest dell, amd, and nvidia technologies to establish the deepsecure hardware infrastructure across the campuses of old dominion university and university of buffalo; (2) developing a new software platform to support deepsecure sde (software development environment) and mec (multi-user experimental chamber). the platform is integrated with pytorch to enable great usability for both beginners and advanced researchers and feature a scalable and customizable modular framework with seamlessly integrated libraries, function blocks, and sample modules; (3) promoting deepsecure across the nation to ensure broad participation, collaboration, and sharing; (4) leveraging deepsecure to foster a long-lasting, self-sustainable ml security and privacy research community that engages all stakeholders in a sustained and ongoing way; and last but not least, (5) educating and training diverse cybersecurity workforce to safeguard the future intelligent cyber systems. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative research: From Community to Practice: Evaluating How Open Educational Resources Facilitate Implementation of Vision and Change Principles Across Diverse Institutions

Awardee: University of Nebraska-Lincoln

Amount: \$778,131.00

Abstract: this project aims to serve the national interest by examining how open educational resources (oers), which are educational materials available in the public domain, have enabled implementation of vision and change (v&c) principles. the v&c report called for biology departments to transform their programs by using student-centered teaching approaches and integrating core concepts and competencies throughout their curriculum. this report also recognized that course transformation represents a major undertaking for individual instructors and that achieving widespread change would require a distributed effort across biology educators. the biology community has responded to this call in a variety of ways, including supporting peer-reviewed oer journal articles that describe structured lessons with demonstrated potential to improve undergraduate student success. however, there has been little work to understand the composition, implementation, and impacts of the v&c principles in oers. by characterizing the existing resources, describing community oer engagement, and measuring oer implementation and student learning, this project has a unique vantage from which to understand at a national level how the v&c call has been realized by the community for the benefit of students. the unifying goal of this project is to advance undergraduate biology education by examining how oer articles have enabled implementation of v&c principles across a variety of undergraduate institution types. despite the potential usefulness of oers, the field lacks a comprehensive understanding of the scope of existing lessons described in articles, how instructors implement them, and whether these resources consistently lead to positive student outcomes. this project will address this gap using an array of data sources, from published oer articles to present day student learning. the project aims to conduct a scoping review of oer article content from a variety of journals. the scoping review will address questions about the coverage of v&c core concepts and competencies; the use of active learning practices; and the advancement of **\*\*diversity\*\***, equity, and inclusion. this project will also survey authors and users to determine their engagement with oers. for authors, the focus will be on

how they construct their lessons with v&c principles and how their institutions reward oer contributions. for users, the focus will be on how they modify lessons for their courses. to further determine how implementation affects student learning, instructors who teach pre-selected oer lessons aligned with v&c core concepts and competencies will share course artifacts (e.g., lecture slides), video recordings of their instruction, and student assessment results. taken together, these data will provide insights into the range of ways that instructors adapt v&c-aligned oers for their own contexts and determine the extent to which lesson components influence student learning across institution types. drawing from emergent research, instructors from a variety of institutions will meet regularly in faculty mentoring networks (fmns) to identify and enact strategies to improve the oer sharing process. these strategies will promote v&c principles through mechanisms such as issuing community calls for specific resource development; reflecting on how oer articles can promote **\*\*diversity\*\***, equity, and inclusion; hosting workshops at home institutions to help colleagues adopt and implement oers; and identifying suggestions for departmental incentives and community supports that encourage increased oer growth. this project will benefit society by understanding how v&c aligned oers can be used to promote student learning in undergraduate biology courses. this project is funded by the program description 21-7412, vision and change that supports projects that study the impact of the vision and change movement in undergraduate biology education. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: GeoGaze: Gaze-Driven Adaptive Multimedia to Augment Geoscience Learning for Neurodiverse Learners

Awardee: University of Florida

Amount: \$774,654.00

Abstract: much of learning occurs today in multimedia environments. this project will design and test

geogaze, a novel technology that uses eye tracking to augment learning with multimedia in real time. geogaze analyzes and predicts effective strategies for students based on differences in working memory capacity and changes the presentation of learning materials to help everyone view and learn information. investigators will first study what visual attention strategies work best for learners with different levels of working memory capacity. this information will be used to build a gaze-driven technology to help each learner use the most effective strategies by adapting the learning materials in real time and for each learner. examples of this include predicting where learners will look on the screen, what order they will explore the content, and then highlighting the most important elements in the sequence to be viewed or blurring the less relevant content before revealing when appropriate. the results of this project will help us understand how individual differences in visual attention and working memory capacity influence multimedia learning and how to adapt learning materials to improve learning in real time. this project seeks to engage more students in learning geoscience, a field not well represented by a **\*\*diversity\*\*** of students and researchers. studies of multimedia learning traditionally focus on final learning outcomes but what happens during the learning process (e.g., visual attention strategies to integrate multimedia) is often unexplored. this project addresses these shortcomings to gain a robust perspective of how students with different working memory capacities learn authentic stem content (geoscience) in multimedia environments, and how their cognition can be enhanced using gaze-driven adaptive learning technology, geogaze. this approach is based on a novel integration of behavioral and psychophysiological data as well as multi-layer backpropagation neural network analysis to predict media integration strategies. geogaze represents a novel gaze-driven technology for adapting multimedia learning in real time based on effective media integration strategies for each learner. this research will generate new empirical evidence for using real-time gaze-driven adaptation of learning materials to augment cognition and improve learning. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: DMREF: Microstructure by Design: Integrating Grain Growth Experiments, Data Analytics, Simulation, and Theory

Awardee: Columbia University

Amount: \$774,628.00

Abstract: most technologically useful materials are polycrystalline microstructures composed of a myriad of small monocrystalline grains delimited by grain boundaries. an understanding of the evolution of grain boundaries and associated grain growth (coarsening) is essential in determining the properties of materials across multiple scales. despite tremendous progress in formulating microstructural models, however, current descriptions do not fully account for various grain growth mechanisms, detailed grain topologies and the effects of different time scales on microstructural evolution. as a result, conventional theories have limited predictive capability. the goal of the project is to develop a predictive theory of grain growth in polycrystalline materials through the construction of novel, closely integrated data-driven numerical simulation and mathematical modeling combined with data analytics, analysis, and a set of critical experiments. this interdisciplinary project, requiring the complementary expertise of applied mathematicians and materials scientists, is firmly aligned with the materials genome initiative. the new knowledge and tools that will emerge from the project will have a profound impact on the performance and reliability of polycrystalline materials used in many technologically useful systems and structures, thereby expediting advanced materials development and deployment. predictive computational algorithms and data will be made available and accessible to other researchers. for the training of the next-generation materials workforce, in addition to mentoring of graduate and undergraduate students, the pi's (from columbia university, illinois institute of technology, lehigh university and university of utah) will participate in outreach activities and will continue to work towards increasing **\*\*diversity\*\*** and broadening participation within stem. grain growth is a very complex process and may be viewed as the anisotropic

evolution of a large metastable network. one of the main thrusts of the project will be to uncover possible stochastic processes that define the evolution of various statistical measures of grain growth, discover relations among them, and establish links to materials properties. results from structure-preserving numerical simulations alongside critical sets of experiments and new experimental data will be invaluable in navigating the modeling and analysis. the project will also create and employ specific data analysis techniques for the study of dynamic evolution of grains in experimental and computational systems with the goal of validating and further refining the microstructural models. this component of the project, will lead to a) the development of new materials informatics methods, b) innovative stochastic differential equations/differential equations models of grain growth, c) new mathematical and numerical analysis techniques for coarsening systems, as well as d) improved computational tools. in turn, the results of combined data analytics, modeling and analysis will be used to guide the design of subsequent experiments. experimentally, grain growth will be examined in prototypical metallic thin films (pd, ni, cr, fe). as most elemental metals and many metallic alloys have cubic structures, the proposed studies will have broad applicability. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: SBP: The Emergence of Social Biases in Infancy

Awardee: University of Chicago

Amount: \$765,000.00

Abstract: this project investigates the developmental origins of social bias. before their first birthdays, infants prefer people from familiar racial groups and people who speak their native language. these biases are related to social experience: infants who have more contact with social **\*\*diversity\*\*** are less biased against people from unfamiliar groups. the proposed studies will shed new light on the mechanisms that give rise to infants' social biases by innovating methods to: (1) assess the emotional and cognitive aspects of infants' biases, (2) investigate the neural systems involved, and (3) identify the aspects of social experience that may be important for establishing social bias. the findings will provide insights into how to mitigate the negative consequences of social biases, as well as developing new research tools for studying relations between behavior, brain and social experience during early development. a major goal of this project is to address the dearth of research with minority populations in cognitive development research. studies will involve equal numbers of infants from minority and majority backgrounds in order to better understand how social biases emerge across the **\*\*diversity\*\*** of human experience. prior research indicates that infants' visual preferences express social bias, but the cognitive and affective processes involved, and the associated social and neural mechanisms are poorly understood. this project addresses these open issues by bringing together an innovative set of behavioral, neural and social measures in research with 9-month-old infants. across six studies, infants will be presented with people from different linguistic and racial groups and infants' brain activity (eeg: frontal-temporal theta; mu

rhythm; frontal alpha asymmetry) and behavioral responses (attention, learning, imitation, and approach-withdrawal tendencies) to members of familiar vs. unfamiliar social groups will be compared. the **\*\*diversity\*\*** in infants? social environments will be assessed via neighborhood census data and a parent survey to assess infants? close social networks. this research will provide fundamental new insights into the nature of infants? social biases and the conditions that contribute to them. the multidisciplinary approach will inform scientific understanding of brain-behavior-environment relations during early development. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Tackling microbial biodiversity to create ecological strategies relevant to soil carbon cycling

Awardee: West Virginia University Research Corporation

Amount: \$756,318.00

Abstract: soil contains the second largest reservoir of carbon on earth. as climate change continues, altered temperature and precipitation can affect soil microorganisms and alter the cycling of carbon in soil, potentially mitigating or exacerbating climate change. the ability of scientists to predict this feedback remains poor, at least in part because the ecology and function of microorganisms in soil is not well understood. further, soil carbon is a mixture of everything from simple sugars to complex plant and microbial debris. this research will determine which microorganisms consume key types of soil carbon. the experimental work will consider a range of soils from distinct regions, climates, and soil types to provide broadly applicable knowledge. the project will test the hypothesis that describing the populations of microorganisms that break down and consume different constituents of soil carbon will improve soil carbon models. accurate predictions of ecosystem feedbacks to global change benefit society by allowing decision makers to prepare for the future. additional broader impacts of this work include experiential learning opportunities for over one hundred high school

students in a rural and economically depressed region of west virginia. the project will contribute hands-on science learning activities to an early college program and stem academy to improve scientific literacy with at-risk, economically disadvantaged, under-served youth in a county where fewer than 10% of adults have bachelor?s degrees. a single gram of soil contains thousands of microbial ?species?, making soils among the most biodiverse habitats on earth. perhaps due to this bio\*\*diversity\*\*, the struggle to connect composition with function in microbial communities persists. this research will connect microbial identity and phylogeny to phenotypic traits by quantifying taxon-specific rates of carbon assimilation and growth. the traits of soil microbes will be leveraged to build ecological strategies that connect them to soil carbon pools and facilitate ecosystem modeling. specifically, the project will test the hypothesis that soil heterotrophs can be grouped as primary decomposers that assimilate complex plant debris, secondary decomposers that assimilate microbial necromass, passive consumers that assimilate labile dissolved substrates and predatory microbes that consume live microorganism. using phylogenetic tools, the researchers will determine whether these ecological strategies are evolutionarily conserved, facilitating connections between taxonomy and function. the empirical data will be used to refine and parameterize a microbial-explicit decomposition model. this effort uses state-of-the-art empirical tools, phylogenetics, and ecological theory to distill microbial communities into a currency that models can directly use to enhance our predictive understanding of soil carbon cycling. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: NSF RUI: Characterizing Adaptation to Heterogenous and Stressful Environments

Awardee: California State University-Dominguez Hills Foundation

Amount: \$753,010.00

Abstract: this project takes advantage of experimental evolution in which organisms are evolved in

the laboratory under defined conditions. experimental evolution has been especially successful with microorganisms because they can grow quickly to large population sizes, making the pace of evolution fast enough to study in short periods of time. in this case, the bacteria are propagated under defined but variable environmental conditions to mimic the stressors bacteria encounter in nature. this project aims to characterize the role of gene expression in adaptation and evolution by focusing on the role of genes that can affect cellular behavior by regulating other genes. mutations in regulatory genes may be particularly advantageous for bacteria in changing environments. this work will be performed in collaboration with undergraduate students at a hispanic and minority serving institution where almost 90% of students are from groups underrepresented in stem. further, the pi will integrate this project into an upper-division microbiology course as an authentic research experience for 48 undergraduate students per year, and perform outreach activities related to this project with k-12 educators. in these ways, the research will help to increase the **\*\*diversity\*\*** of students entering the stem pipeline and leave them better prepared for roles in stem fields.

changes in gene regulation are a driving force for evolution. cis regulatory elements are often the cause of evolutionary change when comparing different species, whereas trans regulatory elements are often altered when organisms need to adapt to changing environments. experimental evolution studies with microbes have begun to probe the role of these factors, but often in unchanging environments where either functional or cis regulatory changes would be favored. the pi will explore the role trans regulatory elements play in adaptation to a heterogeneous environment by first identifying each trans regulatory factor that affects survival of escherichia coli in long-term cultures in complex media. then, the pi will characterize the role of these trans regulatory factors in adaptation, by first correlating the genotype with the transcriptome of the population to identify gene expression changes, and determine which of those changes confer the growth phenotype. the pi will then perform experimental evolution on mutant cells to determine how these mutations may change the evolutionary pathways cells can use to adapt to a heterogeneous environment. understanding how these types of regulatory changes affect adaptation will contribute to the fundamental understanding

of evolutionary principles. this research is funded by the genetic mechanisms program in the division of molecular and cellular biosciences in the directorate of biological sciences. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: NSF Convergence Accelerator Track E: Convergence Towards Nationwide Smart Precision Aquaculture Networks for Sustainable Shellfish Farming

Awardee: University of Maryland, College Park

Amount: \$750,000.00

Abstract: this convergence accelerator project is intended to address the sustainability of shellfish aquaculture. as an important driver of the coastal economy, shellfish aquaculture is the most ecologically sustainable form of aquaculture. shellfish aquaculture offers numerous environmental benefits, and shellfish can serve as a healthy source of protein to enhance human health. however, current domestic shellfish production is bottlenecked by outdated technology and tools. many shellfish farming practices are inefficient, labor intensive, and environmentally destructive. this is

particularly true for on-bottom oyster farming, which has changed little in the past 200 years. this convergence accelerator project will develop a novel framework on nationwide smart precision aquaculture networks (span) to achieve sustainable shellfish production, while preserving healthy marine ecosystems. in the long term, this project will address the global issues of food, planetary resilience, and health as identified by the united nations. the planned education effort will bring philanthropy and social change as a core value for science and engineering education as well as promote **\*\*diversity\*\*** and inclusion. this will help prepare the next-generation workforce to advance the networked blue economy and to improve the health of the planet and quality of life for all. the span framework will be established by using revolutionary concepts empowered by advanced technologies (e.g., internet of things (iot), robotics, and artificial intelligence (ai)), scientific discoveries in biology, environmental science, and ocean sciences, and stakeholder-driven economic development. the project will fundamentally push research boundaries in the following specific directions: i) iot sensor networks will be established to advance the monitoring capabilities for future shellfish aquaculture; ii) novel smart precision harvesting tools based on robotics and automation solutions will be developed to improve farming efficiency and productivity, reduce labor and energy usage, and minimize environmental impact; iii) empirical dynamic models will be created to gain new understanding on feedback between production and environment, as well as to make production predictions; and iv) an optimization framework based on economic models will be established to support production decision-making to gain environmental and economic benefits. collectively, these research activities will ultimately lead to better farm management, economic optimization, and better coping with planetary resilience, and thus enhance production and sustainability. this convergence accelerator project brings together an interdisciplinary team with extensive expertise in sensing and imaging, ai and computer vision, underwater robotics and controls, shellfish biology, climate and ocean dynamics and oceanography, environmental economics, and aquaculture extension, along with readily-engaged stakeholders, in pursuit of research with high impact. the planned education effort will bring change as a core value for science

and engineering education as well as promote collaboration. this will help prepare the next-generation workforce to advance the networked blue economy and to improve the health of the planet and quality of life for all. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Advancing Innovative Convergence Between Fisheries and Offshore Energy to Drive Adaptive Stewardship of Fisheries Habitat in a Dynamic Blue Economy

Awardee: BLUE LATITUDES, LLC

Amount: \$750,000.00

Abstract: for decades, fisheries and offshore energy in the gulf of mexico have developed concurrently, with offshore oil and gas platforms providing fisheries habitats and fishing opportunities for many commercial and recreational fishers. this project will quantify how fisheries use the highly productive artificial reef ecosystems found on offshore oil and gas platforms and produce tools to better understand the impacts of future offshore development (e.g., wind installations) on fisheries. this project will establish the framework for an ecological-economic fisheries model that integrates spatial data from commercial and recreational fisheries and data from ecological parameters, including **\*\*diversity\*\***, abundance, and connectivity, to realize the direct and indirect value that offshore platforms provide for fisheries in the gulf of mexico. the goal is to facilitate decision-making for decommissioning and future offshore energy development that considers the ecological, economic, and social implications of the removal or addition of artificial structures on fisheries. the broader impacts of this project will improve sustainable use of fisheries resources for economic growth, create streamlined pathways to capitalize on existing ocean resources, and improve interactions between disconnected ocean-related sectors in the blue economy, while also providing educational opportunities in the gulf of mexico region.

Title: Collaborative Research: FET: Medium: Robust Quantum Networks via Efficient Entanglement Distribution

Awardee: SUNY at Stony Brook

Amount: \$749,771.00

Abstract: quantum computing has the potential, if realized, to significantly alter the computing landscape. however, building large-scale quantum computers is a key challenge. quantum networks (qns) enable the construction of large, robust, and more capable quantum-computing platforms by connecting smaller quantum computers. networked quantum systems have the potential to significantly alter various activities in society by leading to faster development in medicine and engineering; more secure and privacy-preserving communication; and hitherto infeasible optimizations that leverage the immense computational power to identify efficiencies in manufacturing, logistics, finance, etc. this project is also using the potential and attractiveness of qns to design and offer a variety of educational programs, including a flexible post-baccalaureate program in quantum computing and networking to cater to non-traditional students, improve the **\*\*diversity\*\*** of undergraduate and graduate student body, and develop a quantum capable workforce. building qns that support robust communication across nodes requires several fundamental scientific and technological advances, especially since classical techniques cannot be directly used in the quantum regime. qns can be used to build quantum computing systems that are more capable and more resilient than stand-alone quantum computers. this project is examining the design and implementation of qns from the ground up by developing an infrastructure for efficient communication and management of quantum entanglements in the network. in addition, the project is addressing specific challenges in two key applications of qns: (i) distributed quantum algorithms, and (ii) quantum sensor networks. the project is evaluating the developed techniques using large-scale simulations and over a 6-node qn testbed spread across long island, ny. the testbed is

providing a high-fidelity platform to evaluate the effectiveness of our developed techniques. overall, the project has three research thrusts. in the first thrust, the project is developing an infrastructure to facilitate efficient communication and entanglement management. in particular, it is developing optimization techniques for (i) efficient generation of long-distance entanglement using multiple paths, and (ii) efficient distribution of pre-distributed entanglements. in addition, the project is developing efficient entanglement-distillation strategies in practical settings, and protocols for multicast primitives. in the second thrust, the project is addressing challenges in the context of two key qn applications to corroborate and validate the developed techniques. in particular, the project is developing optimization techniques for efficient distributed implementation of centralized quantum circuits; efficient distributed implementations are important for qn's computational success. in the context of quantum sensor networks, it is designing efficient protocols for the estimation of binary parameter functions and investigating the benefit of entanglements in these settings. in the third thrust, the project is evaluating the above techniques using large-scale simulations and a small qn testbed. to evaluate qn performance effectively, the project is formulating novel performance metrics for qns; this requires non-trivial generalization of the classical network metrics. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: NSF Convergence Accelerator Track E: Reconfiguring Urban Shorelines for Resilience:  
Convergence Research Meshing Ecology, Engineering and Architecture

Awardee: SUNY at Stony Brook

Amount: \$749,688.00

Abstract: abstract - reconfiguring urban shorelines for resilience: convergence research meshing ecology, engineering and architecture. this project addresses a significant national infrastructure need, the replacement of failing shoreline protection in urban areas. it will produce designs that

increase protection, benefit social communities, and maximize the development of shoreline biological communities and the services they provide, including enhancing fisheries. the blue economy includes traditional marine industries, such as fisheries, mining, and trade, as well as emerging industries like offshore renewable energy, and the ecosystem services provided by natural communities, such as carbon sequestration and coastal protection. urbanized coastal zones drive much of the blue economy, but are increasingly vulnerable to damage from waves, flooding, storms, and sea level rise associated with continued climate change. hardened or armored shorelines, such as bulkheads and sea walls, have been the major tool for protecting shorelines from erosion and storms, particularly in urban settings. but, current infrastructure is failing and must be replaced. it is failing physically and functionally as it cannot adapt to changing sea conditions and is deteriorating due to age in many locations. these structures neither support diverse ecological communities nor provides a place for humans to experience and understand the valuable nature of the urban coastal ecosystem. this failure is not only a cause of the impoverishment of urban life, but a contributing factor to the lack of resilience in cities. therefore, there is a need for innovating a new generation of replacements for existing hardened shorelines that will protect the urban edge, while supporting bio\*\*diversity\*\* and expanding human experience at the coastal interface. this project will design a digital prototype that is not only a solution to an urgent problem, but is also scalable and transportable to other urbanized shores within the us and elsewhere. solving problems that are complex and socially relevant requires expertise in a wide range of fields, including fields that do not normally collaborate. this project involves a team from fields that rarely work together including ecologists, engineers, architects, and social scientists. this project will also engage local stakeholders, including underserved communities, to provide education about shoreline issues, science and design evaluation tools, and include their feedback in development of the model. this project will include engagement with industry, agencies, and regulatory bodies, as well as citizen groups and students. to integrate disciplinary knowledge of natural sciences, social sciences, engineering and architecture, with local knowledge, the team will conduct workshop sessions with

stakeholders, including students. interested students will be encouraged to engage as ?citizen-scientist/citizen-designers? for the duration of the project. the research team aims to advance knowledge in 3 ways: 1) within and among disciplines, 2) among citizens, and 3) between experts and citizens. coastal zones are an essential element of the blue economy. they represent the most urbanized and economically productive areas, provide habitat and nursery areas for marine bio\*\*diversity\*\*, and support important fisheries and aquaculture. however, sea level rise and increased risk of storm surge are threatening the people and economic value of urban coastal areas. shoreline hardening has been the major tool for protecting urban areas, but existing structures are failing and need replacement. they have depauperate ecological communities, reduced nursery areas for fish, are ineffective during storm surges, and limit human interaction with the waterfront. therefore, there is urgent need for innovative replacements to protect the urban edge, support bio\*\*diversity\*\*, and elevate human experience. the goal of this project is to design a new type of infrastructure to better protect urban shorelines while simultaneously enhancing local biological communities and human engagement with the coastline. this project will use a convergence, transdisciplinary approach with use of new materials, complex architectural morphologies, and advanced hydrological computer analyses to design new multi-scalar structures and spaces for the urban edge. it will: develop a transdisciplinary framework of structural, material, biotic, economic and social parameters for building new infrastructure to enhance biological and social communities, while advancing protection from sea-level rise and storm surge; use architectural design and engineering modeling to propose new approaches to constructed coastal reinforcements that provide protection for cities and harbors from storm surges and climate change while maximizing development of biotic communities and the services to people. it will be developed as a digital prototype and will engage local stakeholders, including underserved communities, in design activities that will integrate education about shoreline issues, science and design evaluation tools, and will include their feedback. these outcomes will be used to develop guidelines and design principles to improve coastal infrastructure. this project will create pragmatic scenarios on which to

base decision-making for climate-resilient shoreline structures that have greater ecological and social value while upgrading urgently needed mechanical function. the prototype design will deliver a novel model capable of increasing well-being for people, ocean edges, and shoreline species, boost disaster risk reduction, and increase ecosystem and urban services. it will represent a benchmark approach for future research on the development and application of shoreline infrastructure. the team will link fields that rarely interact (natural and social sciences, engineering, and architectural design), with local users, stakeholders, regulatory agencies, and industry through a convergence framework. this project will help advance knowledge, collaboration, and education in 3 ways: within and among previously isolated disciplines, among citizen groups, and between experts and citizens. local users, stakeholders, regulatory agencies and industry will be important components of this interactive team. this project will serve as a platform for developing and implementing this approach through collaboration with the team's convergence network, curriculum integration, strategic network expansion, and pursuit of new allies. network partners will be brought directly into the processes of public space and infrastructure design. this project will have an important outreach to high schools and will engage citizens and students from underserved communities and members of underrepresented groups. project progress, process, and results will be shared to the wider public through a project website, active engagement through various social media and traditional scientific conference presentations and publications. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: CAREER: Experimental tests of competition and facilitation among migratory large herbivores from Yellowstone National Park

Awardee: Brown University

Amount: \$748,079.00

Abstract: a big question in ecology is: "who eats what?" biologists need answers to this question in order to know how food webs are structured. this knowledge is what enables us to understand where species live, how they behave, and whether any disturbances to the system are liable to have adverse effects on the valuable services that nature provides to people. yet despite working to answer this question for more than a century, researchers still struggle to identify all of the feeding links that together create the food webs of ecosystems around the world. this project focuses on the food web of yellowstone national park in order to understand how the diets of bison and other large mammalian herbivores are able to sustain their epic annual migrations across the ecosystem. in a collaboration with the national park service, undergraduates and early career researchers will track the migrations of five iconic species, monitor their foraging behaviors, and develop new types of molecular biomarkers that will enable biologists to measure animal nutrition in the wild. this career project integrates real-world and classroom-based learning objectives that will advance the training of a diverse workforce capable of implementing the types of rapid diagnostic tests that are essential in modern environmental science, healthcare, and epidemiology. the research team will evaluate competing hypotheses about how seasonal changes in plant **diversity** and availability alter the diets of five co-occurring herbivore species: bison, elk, mule deer, bighorn sheep, and pronghorn antelope. a combination of field observations and experiments, fecal dna metabarcoding, and an innovative adaptation of crispr technology for the analysis of animal nutrition will reveal: (i) how variation in animal diets feeds back to influence the structure and composition of vegetation and (ii) how different herbivore species stimulate the production of their own preferred food plants compared to the food plants preferred by other herbivores. results will be used to parameterize a generalizable nutritional model in order to identify competition and facilitation operating in the food web. by developing, testing, and employing novel laboratory methods in combination with a series of time-tested experimental strategies in field ecology, the team aims to overcome the long-standing challenge of precisely characterizing trophic interactions in many research and training programs. this award reflects nsf's statutory mission and has been deemed worthy of support through

evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: NSF Convergence Accelerator Track E: A Globally Coordinated, Universally-Accessible Digital Twin Network for the Coral Reef Blue Economy

Awardee: Woods Hole Oceanographic Institution

Amount: \$747,606.00

Abstract: oia - 2137882 nsf convergence accelerator track e: a globally coordinated, universally-accessible digital twin network for the coral reef blue economythis project proposes to develop a "digital twin" technology to improve stewardship of coral reef ecosystems. digital twins are virtual replicas and the use of this technology is growing in many sectors, providing opportunities to collaborate virtually, visualize entire systems, intake sensor data and update system status in real time, design what-if scenarios, predict results of proposed interventions, and create strategies to improve the real-world features that the twin represents virtually. this technology has not yet been applied to analysis and stewardship of coral reefs but has the potential to facilitate the collaboration among diverse interest groups that is needed to preserve these crucial ecosystems. the team has identified three critical gaps that limit the utility of scientific knowledge in the management, conservation, and restoration of coral reef ecosystems which they are confident can be addressed by the digital twin approach: i) lack of a whole systems approach, ii) absence of a global platform for data integration, analysis and visualization, and iii) lack of universal access to data and knowledge, which in turn prohibits sharing and collaboration. the end goal of the effort is a global-scale, interconnected network of digital reefs with the potential to transform the management, conservation, restoration, and sustainable harvest of coral ecosystems for the 21st century blue economy. coral reef ecosystems play a central role in the global blue economy. in the us, coral reefs contribute billions of dollars to the blue economy each year, create jobs, and protect coastal infrastructure. however, coral reefs everywhere are declining at a pace and scale unprecedented in

human history. this project incorporates valuable **\*\*diversity\*\*** and expertise, including includes the university of guam, an accredited asian american, native american, pacific islander-serving institution; the marshall islands conservation society (mics), with strong stakeholder interests in coral reef sustainability; and the nature conservancy, whose coral reef program is established in over thirty countries around the world. all products generated as part of this research will be made publicly available via a project-specific website and existing portals as well as other media such as film, gamification, and collaborations with large public aquariums in the us. this strong network will help ensure co-development with a broad range of stakeholders and global utilization of the tools developed.      the team will develop the prototype coral reef digital twin on palmyra atoll, a us territory in the pacific, and then during phase 2 will expand the digital twin model to priority sites identified by collaborators from federal agencies and conservation organizations. the 3-dimensional virtual replica of a living reef will facilitate the integration, analysis and accessibility of a **\*\*diversity\*\*** of geological, physical, chemical, biological and socio-economic data and models from anywhere in the world. the data will be incorporated into a holistic representation of the living reef that can be visualized in 3-d, analyzed at any point in space and time, and simulated under different, future scenarios. connection between the physical reef and its digital replica, via sensors, robotics and satellites, will allow the digital twin to receive and integrate updates on coral reef status in near-real time, providing critical information to managers, restoration practitioners, and stakeholders, including tourism operators, fishermen and coastal communities.      this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: RoL: The intersection between cell fate decisions and phenotypic diversification in a rapidly radiating butterfly lineage

Awardee: Smithsonian Institution

Amount: \$747,521.00

Abstract: animal structures are made of combinations and arrangements of distinct cell types, the product of complex cell decision-making during development. but how do cells, which contain identical genetic information, decide their fate? this research addresses this fundamental biological question in a simple, yet spectacularly diverse animal structure?the color patterns on the wings of heliconius butterflies. although heliconius wing patterns are highly diverse, they are created by altering the distribution of just three cell types (red, black and yellow wing scales) across the wing surface. unlike in a complex organ, the cell decisions that create these patterns unfold on a flat canvas of non-migrating cells. this attribute greatly simplifies the process of understanding the interactions among genes and how these interactions change throughout development to create a specific pattern. this research capitalizes on this fact and emerging genomic tools to characterize the molecular decisions that determine how a developing wing cell becomes specified into one of the three different scale cell types. the project is strengthened by a 6-month internship program that targets traditionally underrepresented groups and offers an in-depth research experience and hands-on professional development. moreover, through partnerships with science museums, this project will create bilingual (english and spanish) experiential learning resources that harness the potential of butterflies to educate a variety of audiences (school children, teachers, and life-long learners) about genes, development, natural selection, and the role that interactions among them play in generating earth?s bio\*\*diversity\*\*. evolutionary processes constantly generate and rearrange specialized cell types, forging the morphological dimension of bio\*\*diversity\*\*. research is starting to connect changes in gene expression and open chromatin to cell fate decisions. however, this research has mostly focused on early embryonic development or on the developmental trajectories of complex organs in a few species. although powerful, these studies do not have an explicit goal of linking changes in cell fate decisions to phenotypic change. this research fills this important knowledge gap by characterizing the rules governing cell specification? from signals, to reception, transduction, transcriptional activation, and fate determination during the critical

developmental period when the wing patterns of heliconius butterflies are established. here, extensive knowledge of the ecological and evolutionary significance of wing color patterns, experimental tractability, and fantastic \*\*diversity\*\* make heliconius a powerful experimental system for understanding how the processes of cell specification are modified by natural selection to produce \*\*diversity\*\*. by casting single-cell transcriptomics, open chromatin profiling and crispr loss-of-function experiments within an evolutionary framework that includes replicated cases of the independent evolution of identical wing patterns, this project will determine the rules that govern how cells communicate and acquire a specialized fate during development, and how those rules are applied to generate \*\*diversity\*\*. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: What Black Doctoral Students in STEM Want and What Their Faculty are Giving: How the Differences Impact Students? Mental Health and Career Trajectory

Awardee: Arizona State University

Amount: \$744,966.00

Abstract: to increase the \*\*diversity\*\* of the phd-prepared workforce, understanding underlying issues affecting retention and completion of doctoral degrees is essential. researchers at arizona state university and university of massachusetts boston, propose to study the expressed needs of black doctoral students in relation to faculty perceptions of what they are providing during advising relationships. understanding the mental health impacts of cumulative experiences that marginalize black graduate students, will advance knowledge by providing recommendations for developing inclusive environments and mentoring strategies that are effective at supporting black students. through a two-phase design, the project aims to use detailed interviews regarding the experiences of marginalization, mental health, and career trajectory decisions of graduate students, and faculty

perceptions of supports and contributors or deterrents to providing supports. the project is aligned with the ehr core research program's goal of addressing challenges in stem interest, learning, and participation. the research design is framed by extending role strain theory to include the tension that black students may feel in relationships during graduate programs. the central hypothesis is that intersectional experiences of marginalization and the stem environment among black doctoral students impact mental health and career trajectory decisions. the project aims to understand the contributors and deterrents for faculty to address systemic barriers. a nationwide sampling strategy will include representation from historically black colleges and universities (hbcus), predominately white institutions (pwis), and minority-serving institutions (msis). the project aims to match critical identity aspects in the interviewer-interviewee pairing within each phase of the project. phenomenological principles grounded in a social constructivist paradigm will guide the interpretation of individual interviews. the research responds to the need for understanding barriers to success in graduate programs for black students by novel coordination and expansion of traditional educational research strategies with strategies typically utilized by counseling psychologists. the creation of a tip sheet on promising practices for supporting black students and an online repository aims to inform faculty advisors who seek to improve communication and mentoring for their students. the project is funded by the ehr core research program that supports fundamental research focused on stem learning and learning environments, broadening participation in stem, and stem professional workforce development. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: CAREER: SBP: Understanding how diversity exposure impacts social categorization

Awardee: University of California-Santa Barbara

Amount: \$741,659.00

Abstract: people divide the social world into groups, based on attributes such as race, gender, and nationality. beginning early in life, people use information about another person's groups to form expectations about that person's likely traits and behaviors. even infants expect people in the same group to be similar. expecting people within a group to be similar may lay the foundation for negative stereotypes and bias. one potential way to reduce bias is through positive interactions. past research has shown that positive interactions with someone from an unfamiliar group improves attitudes towards other members of that group. but most communities do not include representation of people from every background. as a result, it is not feasible to have positive interactions with people from all groups. this project develops a new idea: that exposure to **diversity** more broadly (rather than to a specific group) may itself reduce stereotyping. this idea is tested by developing measures of the racial and linguistic **diversity** of infants' and children's neighborhoods and networks along with traditional measures of stereotyping. the project develops novel measures of exposure to **diversity**, based on the principle of entropy: networks that contain a greater number of groups and with more equal representation of groups are scored as more diverse. by pairing this novel measure with other validated measures of children's stereotyping, the research will test whether differences in exposure to **diversity** are related to differences in stereotyping. this approach helps to address a number of fundamental questions. one is whether exposure to racial **diversity** reduces race-based stereotyping. another is whether the effects of **diversity** exposure are even broader, such that exposure to linguistic **diversity** can reduce race-based stereotyping. a third is how children's stereotyping based on racial groups compares to linguistic groups. the broad aim is to better understand how early exposure to **diversity** is related to stereotyping in infants and children. the laboratory-based research is a critical first step that can be leveraged for future interventions aimed at mitigating the negative impacts of stereotyping. the project also provides training in social psychology and developmental science for a diverse group of early-career researchers, and supports partnerships between the university and local museums aimed at increasing scientific literacy. this award reflects nsf's statutory mission and has been

deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: PurSUIT: Species diversity and evolution of parasitic microfungi

Awardee: Purdue University

Amount: \$739,694.00

Abstract: fungi are essential to ecosystem functioning, occur virtually everywhere, and form complex relationships with diverse organisms including prokaryotes, algae, plants, invertebrates, vertebrates, and other fungi. nonetheless, fungi are the most undersampled and poorly documented major lineage of eukaryotes, even though total species estimates range conservatively from 1.5-6.1 million species. this uncertainty reflects numerous gaps in knowledge about fungal distributions, especially regarding range and extent of unculturable fungi, microscopic fungi (microfungi), parasitic fungi, and tropical fungi. this project will document **diversity** of fungi in two groups that represent major gaps in our knowledge: the first are unculturable microfungi that associate with insects, called labouls, and the other are unculturable microfungi that associate with plants, called rust fungi. members of labouls and rust fungi are expected to have profound effects on ecosystem health and functioning through both beneficial and harmful interactions with their animal and plant hosts. the research team will explore several global habitats in tropical and temperate regions that have not previously been surveyed for these fungi. it is expected that hundreds of new species will be discovered and described during this project. in addition to enhancing the documented bio**diversity** on the planet, this project will resolve the "tree of life" for both groups and use this information to resolve long-standing questions regarding the evolution of the fungi. broader impacts include graduate and undergraduate training, international workshops to enhance collaboration between us and local researchers, and outreach to the public through "bat night" and "roach hunt" field trips. these fungal lineages are being studied for several reasons: 1) both represent groups poorly documented

from tropical world regions; 2) both represent groups that are not detected by commonly applied culture-based and high throughput sequencing efforts; 3) neither group has been resolved, phylogenetically, by application of multi-locus analyses of known species; 4) both represent obligately parasitic lineages that are rarely studied but expected to have profound effects on ecosystems; and 5) both are or are related to heteroecious fungi (requiring two different hosts), a phenomenon that is extremely rare in fungi. a complementary team of us and other global experts on these fungi, ranging from junior to senior scientists, have designed an experimental approach that includes standardized sampling strategies from tropical and extra-tropical regions with multi-locus phylogenetic, phylogenomic, comparative genomic, and statistical analyses to: 1) determine whether accurate estimates from obligate microparasitic fungi, not included in any other estimates, will affect overall fungi species estimates; 2) whether parasitic microfungi follow the reverse latitudinal gradient posited for other fungal groups; and 3) resolve long-standing unresolved phylogenetic nodes by the incorporation of ?missing? lineages. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: GCR: Collaborative Research: Designing a Sustainable Agricultural Production System through Convergence Research Using a Multi-Scale Ecosystems Approach

Awardee: Tulane University

Amount: \$739,184.00

Abstract: this project addresses the grand challenge of sustainability of food systems, a complex issue that requires deep integration of scientific and engineering disciplines as well as participation by all stakeholders. this project brings together conservation biologists, ecologists, agronomists, farmers, indigenous peoples, economists, social scientists, land managers, and engineers to co-design and implement a framework for testing approaches to sustainable agricultural production.

the research team will use this to study the impact in a model system, coffee production, of integrating technological innovations, such as us-built, industrial renewable-energy dryers and clean wet mills that recycle coffee pulp and reduce water pollution, with environmentally-friendly economic development where farmers are compensated for preserving forest on their lands through carbon offset credits, and community-led training and outreach and microcredit programs intended to increase both the participation of women and production. such a system has the potential to conserve forest critical to reducing carbon emissions, support bio\*\*diversity\*\*, including migratory birds, and enhance the stability of economic and social conditions. the goal of the project is to develop a framework for convergence research targeting the development of sustainable food systems using the tools of socio-ecological systems, extended to a multiscale ecosystem framework. the research team will construct a multi-scale empirical socio-ecological model of the food production system, identifying the structural elements at all relevant scales, the inter- and intra-scale interactions among those elements, and ecosystem and social services at multiple scales. this model will allow quantification of sustainability metrics under different scenarios. it will be used to identify tradeoffs, synergies and critical points among sustainability indicators and to perform scenario analyses of the impacts of critical exogeneous drivers, including market fluctuations and climate change, on the elements of the system. this project is jointly funded by the growing convergence research program and the established program to stimulate competitive research (epscor). this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: NRT-QL: A Program for Training a Quantum Workforce

Awardee: San Jose State University Foundation

Amount: \$739,029.00

Abstract: recent progress in quantum information science and technology (qist) promises advances that will fundamentally reshape today's leading technologies, including computing, communications, and sensing. a well-prepared workforce is essential to fulfilling this promise. in response to this critical workforce need, this national science foundation research traineeship (nrt) award to the colorado school of mines (mines) and san jose state university (sjsu) supports the development of rigorous, integrated, interdisciplinary training programs preparing both master's and doctoral students for careers in qist. the program has three components that address key challenges in training a quantum workforce. first, new training materials will be developed to introduce qist basics to students from different disciplines. trainees will come from physics, electrical engineering, metallurgical and materials engineering, applied mathematics and statistics, computer science, and quantum engineering. second, industrial and national lab partners will be engaged to provide trainees access to cutting-edge technologies and research experiences. finally, student recruitment and mentoring programs, unconscious bias training, ally workshops, and regular climate surveys will be developed to ensure **\*\*diversity\*\*** in the qist workforce. the project will train one-hundred and twenty-five (125) ms and ph.d. students, including thirty-five (35) fully-funded trainees. these efforts will result in an institutionalized program that produces leaders in qist for careers in academia, industry, government, and national labs. the research program addresses three grand challenges in quantum technology: (1) how can demonstrable quantum speed-up using existing or near-term quantum computing architectures be achieved? (2) how can materials and electrical engineering interface with quantum technology to provide meaningful advances in device development and fabrication? (3) how can new directions in quantum algorithms advance and challenge the notion that quantum technology can solve problems that are impossible to tackle with conventional technology? these interdisciplinary research challenges require close synergy between fundamental physics, materials science, electrical engineering, and algorithm development. new courses and degree pathways in qist are being developed at both mines and sjsu, which include integration of professional skills development into the graduate curriculum. through classroom training and

research, trainees will be exposed to the full range of quantum technology architectures, providing a holistic view of this rapidly developing field. an innovative educational agreement between mines and sjsu will provide opportunities for students to complete an ms/ph.d. bridge program from sjsu to mines. the program will result in a template for qist graduate education, which will be accessible to stem students from all backgrounds and types of institutions, increasing **\*\*diversity\*\*** in qist. the nsf research traineeship (nrt) program is designed to encourage the development and implementation of bold, new potentially transformative models for stem graduate education training. the program is dedicated to effective training of stem graduate students in high priority interdisciplinary or convergent research areas through comprehensive traineeship models that are innovative, evidence-based, and aligned with changing workforce and research needs. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: CAREER: Incorporating host phenology into the framework of biodiversity-disease relationships

Awardee: Purdue University

Amount: \$738,584.00

Abstract: major changes to bio**\*\*diversity\*\*** are occurring around the world - this can alter the risk of disease. understanding and predicting how these changes impact infectious disease requires knowledge of the relationship between bio**\*\*diversity\*\*** and disease. however, because bio**\*\*diversity\*\*** may vary throughout the year, it can be difficult to measure host **\*\*diversity\*\*** and the contribution of each species to disease transmission. therefore, scientists must understand how the seasonality of organisms in a community affects the risk of disease. in this project, researchers will study seasonal changes to amphibian bio**\*\*diversity\*\*** and how these changes impact infection with a fungus. a greater understanding of bio**\*\*diversity\*\***-disease relationships is essential for effective

control of emerging infectious diseases and management of susceptible species. this career project also incorporates educational activities that focus on increasing the **\*\*diversity\*\*** of students who receive training in the scientific process by providing research opportunities for undergraduate and high school students. this study will combine field sampling, experimental manipulations, and modeling to incorporate host phenology into the study of bio**\*\*diversity\*\***-disease relationships. the project focuses on the following complementary objectives: (1) enhance estimates of host competence for individual species by incorporating data on temporal habitat use, (2) quantify the temporal niche of a pathogen in communities with varying species composition, and (3) predict the effects of climate change on disease risk via altered host phenology. this work will address these objectives by utilizing an amphibian-fungal pathogen system, where the presence of amphibian host species in the aquatic environment varies seasonally and across space. the educational objectives of this career project focus on increasing the **\*\*diversity\*\*** of students receiving quality training in the scientific process. educational activities include (1) improving the availability of course-based undergraduate research experiences, (2) increasing the **\*\*diversity\*\*** of undergraduate research interns, and (3) engaging high school students in research through participation in science fairs. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Increasing the Number and Diversity of Highly Effective STEM Teachers in High-need Urban School Districts

Awardee: Davenport University

Amount: \$737,538.00

Abstract: this project aims to serve the national need for highly effective, diverse stem teachers in high-need urban schools. over the next decade, teacher preparation efforts will be challenged by school administration turnover, social and policy changes, and demographic shifts. thus, preparing excellent teachers will become even more important. this project is designed to increase interest in teaching careers among high school students, community college students, undergraduate stem majors, and stem career changers. the project features an innovative pipeline development approach that includes recruiting potential teachers from urban high-need high schools and by developing dual enrollment programs that accelerate college degree attainment. by offering early teaching experiences to high school and undergraduate students, the project has the potential to increase student interest in teaching. since many of these teaching experiences will be conducted as service-learning projects, these efforts will benefit the community as well. the project will leverage stem teaching methods courses and undergraduate urban education courses to help prospective teachers understand the context of urban education, including challenges and data-driven educational strategies that increase student achievement. this project at davenport university (du) includes partnerships with grand rapids community college and four high-need local educational agencies (detroit public schools community district, muskegon heights public school academy system, hope academy of west michigan, and grand rapids public schools). the project aims to strengthen the recruitment pipeline and increase the size and **\*\*diversity\*\*** of the pool of eligible stem candidates in du's urban education teacher preparation program. the project aims to recruit, provide scholarships or stipends, educate, and graduate 23 prospective stem teachers. these students will include 15 eligible juniors and seniors pursuing a bachelor of science in computer science or biological laboratory science and 8 stem professional career changers. these prospective teachers will be prepared to gain michigan k-12 teacher licensure with a focus on biology, chemistry, physics, integrated science, and/or mathematics. they will also gain experience in implementing

culturally relevant pedagogical models of instruction. upon certification, the new teachers will receive mentoring, academic resources, and induction support to successfully transition into a teaching career in high-need, urban school districts. the project will collect data and analyze how service-learning experiences, mentoring, coaching, and an enhanced curriculum emphasizing culturally responsive teaching practices prepares prospective stem teachers to be successful stem teachers in urban stem classrooms. this track 1: scholarships and stipends project is supported through the robert noyce teacher scholarship program (noyce). the noyce program supports talented stem undergraduate majors and professionals to become effective k-12 stem teachers and experienced, exemplary k-12 teachers to become stem master teachers in high-need school districts. it also supports research on the persistence, retention, and effectiveness of k-12 stem teachers in high-need school districts. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: The Simpson Neutron Monitor Network

Awardee: University of New Hampshire

Amount: \$730,638.00

Abstract: this award is funded in whole or in part under the american rescue plan act of 2021 (public law 117-2). this three-year collaborative project is focused on building of a network of ground-based cosmic-ray monitors, called neutron monitors (nms), operated by a consortium of three u.s. academic institutions, namely universities of new hampshire, delaware and wisconsin-river falls. invented by prof. john simpson in 1948, following his experience on the manhattan project, nms have been used to detect and measure radiation in space, starting almost ten years before the space age. they are stationed on the ground all over the globe, providing continuous measurements of cosmic radiation for over a half century. nms measure the trends and changes in the radiation

levels in space, which is critical information for travel by astronauts to the moon and mars. they can also detect intense, short-term bursts of radiation from the sun that reach the ground. all this activity is driven entirely by what the sun is doing. nms are robust and reliable and have assumed a new importance in recent years when used in conjunction with the international fleet of spacecraft and with neutron monitors in other countries. now, all the nms sponsored by the u.s. are being linked into what will be the simpson neutron monitor network, which will make it more efficient to coordinate operations and science. during this three-year collaborative project, the consortium will carry out this research, teasing new information out of these heritage instruments and providing researchers around the world with up-to-date radiation climate data. cosmic rays entering the earth's atmosphere are messengers informing us about large-scale heliosphere structure, local space environment and solar activity. they have already passed through and interacted with the interplanetary magnetic field, and they carry information of its detailed structure. some of these cosmic rays possess enough energy to reach the ground. a nm is a ground-based particle detector that records the nucleonic component in particle showers. this directly correlates with the number of high energy cosmic rays striking the earth's atmosphere. the analysis of these data is used to build an understanding of the sun's influence on the solar system. because of the large detector volume exploited by ground-based stations, neutron monitors remain the state-of-the-art instrumentation for measuring rigidity  $>1\text{gv}$  cosmic rays. the programmatic linking of these instruments run by the universities of new hampshire, delaware and wisconsin-river falls will secure a continuity of quality data for the global community, as called out in the national space weather plan and congressional legislation. the data from these instruments are used by many, including, space weather predictors, industry, space scientists, homeland security and hydrologists. the nm stations span a wide range of latitudes, from the south pole to the arctic regions. the contributors to the nm signal include cosmic rays from the galaxy that are heavily modulated by solar activity and from the sun itself in the form of high energy bursts of protons. the variability of these agents reveals conditions in interplanetary space, general solar activity and the fundamental processes that produce cosmic rays throughout

the universe. with today's computing resources, we better understand how these instruments detect radiation, and the consortium will thus be able to extract new information from these workhorse devices. this will shed new light on how the distribution of cosmic rays varies with time, geography and particle energy. the consortium will study how to permanently secure the operations of the monitor network and intelligent ways of expanding the network to complement those at existing sites. the education and outreach goals of the project include a research position for a postdoc, a wide variety of opportunities and experiences for undergraduates, as well as opportunities for high school and elementary school students. the research and education agenda of this collaborative project supports the strategic goals of the agency division in discovery, learning, **diversity**, and interdisciplinary research. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: CAREER: Wood-eating protists: An evolutionary transition enabled by gene transfer?

Awardee: Arizona State University

Amount: \$725,355.00

Abstract: wood-feeding termites can be highly destructive pests. their ability to survive on such a nutritionally poor diet as wood comes from symbiotic gut microbes. in certain termites, these microbes include protists (protozoa) that can engulf wood particles and extract sugars using specialized enzymes. this project will determine how the protists evolved their wood-digesting ability. did they acquire new genes for wood-degrading enzymes from bacteria or fungi, or did they adapt enzymes that are also present in non-termite protists? a better understanding of wood digestion in protists could be useful for developing termite control strategies or learning how to convert woody biomass into biofuels or other biochemicals. because most termite protists have not been studied, this project will also illuminate a dark area of the tree of life by describing many new protist species

and determining how they are related to one another and to non-termite protists. as part of the bio\*\*diversity\*\* discovery and documentation effort, a course-based undergraduate research experience at arizona state university will train approximately 200 students in systematics and bio\*\*diversity\*\* research. the research activities will include transcriptome sequencing of 43 protist species, 31 from termite-associated lineages and 12 from related, non-termite lineages. these transcriptomes will be studied to determine the \*\*diversity\*\*, distribution, and phylogeny of cellulases and hemicellulases in the protist superphylum metamonada. transcriptomic data will also be used for phylogenomic analyses to resolve the protist phylogeny and provide a framework against which to interpret the evolution of wood digestion. because termite gut protists are so understudied, an additional ~200 protist species symbiotic in 21 phylogenetically diverse termite species will be characterized by morphology and 18s rRNA sequence by single cell PCR. this number includes an estimated 50-70 currently undiscovered species that will be formally described. the characterization of arizona termite protist species will be carried out by teams of undergraduate students receiving training in taxonomy and systematics as part of a course-based research experience (CURE). involvement in authentic research has been shown to increase undergraduates' appreciation of and retention in science. the proposed CURE will specifically target first-generation college students, including transfer students from a local community college. research results will be disseminated broadly to protistology, microbial ecology, and termite specialist communities through conferences and the biennial international termite course at the university of florida. this award reflects NSF's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: MRI: Acquisition of a Massive Database to Accelerate Data Science Discovery

Awardee: University of Vermont & State Agricultural College

Amount: \$725,016.00

Abstract: this project is jointly funded by the major research instrumentation and the established program to stimulate competitive research (epscor) programs. the project funds construction of datamountain, a massive database cluster for high performance computing at the university of vermont (uvm). the large-memory machine will enhance the vermont advanced computing core, a virtual laboratory supporting the research of over 500 scientists in the state of vermont. with so many fields transitioning from data-scarce to data-rich environments, many important research areas will benefit from this new machine including research into addiction, mental illness, climate change, drug discovery, food systems, and the spread of online misinformation. datamountain will allow for fast access to enormous datasets, supporting several projects that require computational power and speed to effectively analyze, describe, and explain rapidly growing datasets. datamountain will increase by nearly two orders of magnitude the largest random access memory machine available for computational research at uvm, accelerating large-scale data-driven research requiring rapid reading and writing, and facilitating a broad and diverse set of important scientific investigations not currently possible given the existing hardware. it will also enhance the functionality of the high performance computing clusters bluemoon and deepgreen, which are dedicated to parallel processing and machine learning respectively. for example, the machine will allow for interactive access to over 50 terabytes of social media data through <http://storywrangling.org> and <http://hedonometer.org> for timely analysis of changes related to the covid-19 pandemic in population-scale physical and mental health data. in addition, datamountain will allow for massive increases in the spatial and temporal resolution of computational chemistry simulations being performed for data-driven design of next-generation antimicrobial peptides to combat antibiotic resistance. datamountain will also enable exploration of petabytes of fmri, genetic, task performance, and survey data associated with 10,000 adolescents across the united states over the next decade. in addition, the machine will accelerate research using unmanned aerial surveillance imaging for tree canopy assessments, facilitate network science modeling of agricultural **\*\*diversity\*\*** of crops and nutritional outcomes globally, and help quantify the impacts of the covid-19 pandemic

on food insecurity. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: CAREER: Emergence of Functional Organization in the Adaptive Immune System

Awardee: University of Washington

Amount: \$720,000.00

Abstract: it takes decades for humans to reproduce, but our pathogens can reproduce in less than a day. how can we coexist with pathogens that can evolve more than 10,000 times faster than us? the answer lies in our adaptive immune system, which is a self-organized system of highly diverse immune cells that develop during the lifetime of an organism. the adaptive immune system incorporates all aspects of life, from molecular signaling to cellular evolution. the result is an information processing molecular organization with many interacting components, which can reliably sense and adaptively respond to diverse and evolving pathogens. the vast differences in immune repertoires between individuals suggest the existence of many molecular solutions to statistically similar pathogenic environments. the goal of this project is to use machine learning to derive a map from the diverse and high-dimensional space of receptor repertoire sequences to a lower dimensional space of immune functions that relates to biophysics of immune recognition. this effective functional representation of immune repertoires would allow construction of predictive models for immune responses to pathogens, and will shed light on functional organization of immune repertoires. to bridge the gap between physics and biology, the pi will introduce pre-college and undergraduate students to biophysics research, with particular emphasis on women and underrepresented minorities. the pi will create new teaching modules to introduce both the physics and the life-science undergraduate and graduate students to current progress in physics of living systems. in addition the pi will commit significant resources to mentor undergraduate and high

school students during summers and the academic year to pursue biophysics research. the pi will invite biophysics researchers to the department's "frontiers of physics public lecture series", to foster an appreciation and support among the community for the exciting developments in this field.

the adaptive immune system develops during the lifetime of an organism and consists of highly diverse b-and t-cells, whose unique surface receptors are generated through genomic rearrangement, mutation, and selection. this diverse repertoire of receptors can mount specific responses against a multitude of evolving pathogens and keep a memory of past infections for future encounters. pathogens in return, evolve to escape the immune challenge, forming a rapid co-evolutionary arms race during the life-time of an organism. over the past decade, high throughput immune repertoire sequencing has been instrumental in characterizing the **diversity** of immune receptor sequences. however, we still lack an understating of how receptor sequence **diversity** translates to immune function. in this project, the pi will combine theoretical modeling with inference from molecular data to uncover the biophysical and evolutionary basis of the functional organization and encoding of pathogenic information in the adaptive immune system. the life-cycle of immune cells is defined by a continuum of selection stages leading to their functional specialization. the pi will develop biophysical inference techniques to leverage receptor repertoire data of distinct immune cell-types and use machine learning to derive sequence-determinants of immune function. in addition the pi will develop predictive fitness models to characterize how the short-and long-term dynamics of immune repertoires relate to functional responses to pathogens. by building upon recent advances in machine learning, the pi will infer a latent representation (i.e., a shape space) for immune receptors that reflects the relevant biophysics of immune recognition and function. the inferred immune shape space will allow to ask fundamental questions regarding the biophysical determinants of antigenic interactions, and self/non-self discrimination. lastly, a theoretical framework to study how the co-evolutionary history of hosts and pathogens has shaped immune strategies, both at the individual-and the population-level will be developed. this award reflects nsf's statutory mission and has been deemed worthy of support

through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Nonclassical mechanisms to modify and control organic crystal nucleation and growth

Awardee: University of Houston

Amount: \$714,558.00

Abstract: non-technical summary    solution-grown single crystals serve as semiconductor, optoelectronic, and photovoltaic devices and detectors for high-energy radiation. these studies, supported by the solid state and materials chemistry program in the division of materials research, fill a gap in understanding crystallization of organic materials that carry promising optical and electronic properties for use as semiconductors, solar cells, and field-effect transistors. additionally, the research can provide valuable information about crystallization processes, which are essential for a myriad of industrial, natural, and physiological processes. researchers at the university of houston take on the grand fundamental science challenge to control crystallization by designing robust control strategies that rest on understanding the fundamental thermodynamic and kinetic mechanisms, and in particular the role of foreign compounds. in industry, soluble foreign compounds that interact with the solution or the crystal-solution interface are deployed to promote or inhibit crystallization. nature achieves remarkable **\*\*diversity\*\*** of shapes, patterns, compositions, and functions of the arising crystalline structures by applying ingredients that control the number of formed crystals and their rates of growth. insights gained from this project advance the science of organic crystallization in general, and the influence of foreign compounds on the synthesis of solid state organic materials in particular. the researchers also involve a diverse cohort of high school, undergraduate, and graduate students in carrying out this research, which provides them with training in advanced science and engineering concepts and methods. this in turn contributes to narrowing the gap between the demand and availability of educated workforce in houston, which is among the widest in large u.s. cities.    technical summary    as part of this project, which is supported

by the solid state and materials chemistry program in the division of materials research, the pi and this team design novel strategies to control the nucleation and growth of crystals from organic solvents that employ foreign compounds to regulate nonclassical crystallization behaviors and the nucleation and growth precursors. the accepted models of modifier activity presume that crystal nucleation and growth advance along classical pathways. recent experiments have accumulated significant discrepancies with the classical theories. the highlighted nonclassical features involve mesoscopic crystallization precursors, ordered or disordered, which assemble in the solution independently of crystallization and may both facilitate nucleation and feed a fast mode of crystal growth. how additives impact the properties of the crystallization precursors to enhance or suppress crystal nucleation and growth has not been examined. the researchers bring complementary expertise in molecular thermodynamics and kinetics of crystallization, crystal design and advanced characterization, and molecular simulations to pursue three specific aims: 1. design strategies to control crystal nucleation by manipulating precursors involved in nonclassical nucleation modes. 2. elucidate molecular and mesoscopic crystallization mechanisms that persist after removal of the modifier from the growth medium by exploiting the interactions of modifiers with crystal growth precursors and with step bunches on the crystal surface. 3. characterize interactions between pairs of modifiers mediated by the step structures and dynamics that lead to antagonistic, additive, or synergistic cooperativities between modifiers; these interactions have been disregarded by classical inhibition models. to cover a diverse array of nucleation and crystallization behaviors, the researchers employ organic crystals that carry promising optical and electronic properties for use as semiconductors, solar cells, and field-effect transistors. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: RoL: The intersection between cell fate decisions and phenotypic

diversification in a rapidly radiating butterfly lineage

Awardee: Duke University

Amount: \$710,178.00

Abstract: animal structures are made of combinations and arrangements of distinct cell types, the product of complex cell decision-making during development. but how do cells, which contain identical genetic information, decide their fate? this research addresses this fundamental biological question in a simple, yet spectacularly diverse animal structure?the color patterns on the wings of heliconius butterflies. although heliconius wing patterns are highly diverse, they are created by altering the distribution of just three cell types (red, black and yellow wing scales) across the wing surface. unlike in a complex organ, the cell decisions that create these patterns unfold on a flat canvas of non-migrating cells. this attribute greatly simplifies the process of understanding the interactions among genes and how these interactions change throughout development to create a specific pattern. this research capitalizes on this fact and emerging genomic tools to characterize the molecular decisions that determine how a developing wing cell becomes specified into one of the three different scale cell types. the project is strengthened by a 6-month internship program that targets traditionally underrepresented groups and offers an in-depth research experience and hands-on professional development. moreover, through partnerships with science museums, this project will create bilingual (english and spanish) experiential learning resources that harness the potential of butterflies to educate a variety of audiences (school children, teachers, and life-long learners) about genes, development, natural selection, and the role that interactions among them play in generating earth's bio\*\*diversity\*\*. evolutionary processes constantly generate and rearrange specialized cell types, forging the morphological dimension of bio\*\*diversity\*\*. research is starting to connect changes in gene expression and open chromatin to cell fate decisions. however, this research has mostly focused on early embryonic development or on the developmental trajectories of complex organs in a few species. although powerful, these studies do not have an explicit goal of linking changes in cell fate decisions to phenotypic change. this research fills this

important knowledge gap by characterizing the rules governing cell specification? from signals, to reception, transduction, transcriptional activation, and fate determination during the critical developmental period when the wing patterns of heliconius butterflies are established. here, extensive knowledge of the ecological and evolutionary significance of wing color patterns, experimental tractability, and fantastic **\*\*diversity\*\*** make heliconius a powerful experimental system for understanding how the processes of cell specification are modified by natural selection to produce **\*\*diversity\*\***. by casting single-cell transcriptomics, open chromatin profiling and crispr loss-of-function experiments within an evolutionary framework that includes replicated cases of the independent evolution of identical wing patterns, this project will determine the rules that govern how cells communicate and acquire a specialized fate during development, and how those rules are applied to generate **\*\*diversity\*\***. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Disentangling biological and environmental drivers of diversification in the Andean flora

Awardee: Louisiana State University

Amount: \$709,712.00

Abstract: the tropical andes of south america is one of the world's richest bio**\*\*diversity\*\*** hotspots. this **\*\*diversity\*\*** likely evolved due to the complex environmental and geological history of this region. however, exactly how plant **\*\*diversity\*\*** arose from the combination of mountain uplift, the development of new habitats, and species interactions is unclear. this research aims to understand how these factors led to plant **\*\*diversity\*\*** in cloud forests and high-elevation grasslands. the researchers will develop new software to compare plant genomes to understand the ancestry of four groups of flowering plants in the andes. the project will also result in new mathematical models to

test the importance of different factors in shaping **diversity** in these plant groups. these new methods will have broad application to studies of bio**diversity** in the andes and beyond. additionally, this project aims to train the next generation of scientists in the study of bio**diversity** through a variety of interrelated activities, including: (1) a course for undergraduates to do guided genomic research; (2) collaborative training for students; and (3) computational training for diverse students. the project will first establish well-supported phylogenetic hypotheses for each of the four focal clades of andean plants using low-coverage and targeted genome sequence data. samples will be collected from colombia as well as museums. this work highlights the importance of natural history collections in cutting-edge biological research, and new fieldwork will add to those collections. a component of the research will be to develop new approaches to address complexities common in plant genomes, including polyploidy and paralogy, that can affect estimates of evolutionary relationships. these methods will be made available through open-source software such that other researchers can easily estimate phylogenies and examine support for phylogenetic hypotheses using sequence data. second, the project will develop new models that jointly infer the roles of dispersal and trait evolution in species diversification. these methods will be applied to phylogenomic, morphological, and distribution data collected for this project. these methods will also be made publicly available for widespread use. finally, by comparing the roles of biogeographic and ecological processes in generating **diversity** in these clades, the research will address the generality or idiosyncrasy of the processes facilitating rapid radiation in tropical andean plants. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: IUCRC Phase 1: The City College of New York: Center for Building Energy Smart Technologies (BEST)

Awardee: CUNY City College

Amount: \$706,349.00

Abstract: the building energy smart technologies (best) iucrc brings together universities and industries to transform the building industry through the development and adoption of sustainable and intelligent technologies. best will apply innovative, energy-smart technologies through a wide spectrum of us buildings. best will be located in two sites: the lead site at university of colorado boulder (cub) and the partner site at city college of new york (ccny), taking advantage of the diverse academic, natural and industrial environments these locations provide. the best center will foster smart, sustainable, and efficient development and utilization of energy in the built environment through an integrated systems approach to design, retrofit, construct, and operate sustainable buildings and cities. ultimately, the best center will support the u.s. building industry's efforts to meet increasingly stringent building energy-efficiency regulations, and society's expectations for

improved sustainability, resiliency, and security in communities and cities. the best center will support the goal of achieving net-zero greenhouse gas emissions by 2050. moreover, the center will educate and train a skilled and diverse workforce to address current and future employment needs for the u.s. building industry. the best center will enable the development of new and sustainable building energy technologies through a holistic understanding of the interactions between built and-natural systems. in particular, the center will address design and operation solutions for the built environment associated with extreme weather events, which are becoming more frequent and intense due to a rapidly changing climate. additionally, the center will focus on the emerging challenges in the building sector due to pandemics and health crises such as those caused by covid-19, and increase cybersecurity of the buildings systems and of occupants? privacy. the center?s research scope spans various disciplines specific to building energy systems, including indoor-outdoor energy flows, advanced building envelope systems, demand-response informatics, application of advanced in-situ and remote sensing for monitoring the environment and occupants, and distributed energy efficient and renewable technologies. to cover the rich and wide \*\*diversity\*\* of the building industry needs, five thrust areas are proposed for the center?s research activities: (i) smart buildings materials, (ii) intelligent building mechanical and electrical energy systems, (iii) distributed and renewable energy systems, (iv) city-scale building energy systems and informatics, and (v) smart grid systems integrated with distributed energy and data systems. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Measurements of stable carbon isotopes on board GO-SHIP cruises in the South Atlantic Ocean to enhance our ability to quantify anthropogenic CO<sub>2</sub> uptake rates by the ocean

Awardee: University of Delaware

Amount: \$702,050.00

Abstract: rising carbon dioxide concentrations in the atmosphere, global climate change, and the sustainability of the earth's biosphere are of great scientific and societal concern. approximately one-quarter of fossil fuel emissions of carbon dioxide emitted each year are absorbed by the oceans, and it is important to understand where and how fast this process occurs. stable isotopes of carbon can be used as a "signature" to identify fossil fuel-derived carbon dioxide in the atmosphere and ocean. the investigators have developed a new method for measuring the stable carbon isotope composition of dissolved carbon dioxide rapidly and precisely while at sea. they will measure several thousand samples on two research expeditions to the south atlantic ocean. they will compare their measurements to ones made in the same locations approximately ten years earlier, and determine the amount of carbon dioxide absorbed over that time period. the proposed research will enhance ocean carbon research infrastructure, general science education, and public awareness of climate change and environmental issues. the investigators plan to enhance \*\*diversity\*\* in earth sciences by recruiting underrepresented minority students in the research and have a graduate and an undergraduate student involved in all phases of this project. the team, including the students, will actively disseminate the research results in international, national, regional, local education and outreach activities, and in peer-review journals.

in the south atlantic ocean, anthropogenic  $\text{CO}_2$  uptake rates are high and variable as mode and intermediate waters are formed and are sensitive to climate changes. the carbon-13 suess effect makes  $\delta^{13}\text{C}-\text{CO}_2$  in the atmosphere a clearly defined endmember and  $\delta^{13}\text{C}-\text{DIC}$  in the ocean a powerful tracer to independently estimate anthropogenic  $\text{CO}_2$  uptake and storage in the ocean. the team has developed a precise, rapid, and sea-going method to simultaneously measure dissolved inorganic carbon (DIC) concentration (to plus or minus 2 micromol per kilogram) and stable carbon isotope composition ( $\delta^{13}\text{C}-\text{DIC}$ ) (to plus or minus 0.03 permil) by combining a  $\text{CO}_2$  extraction device with a cavity ring-down spectroscopy (CRDS) isotope analyzer. they will use this method aboard go-ship cruises a13.5 and a16s to analyze about 1000 samples onboard the ship and 2000 samples on land for each cruise. extensive evaluation and comparison of this method with the traditional isotope ratio mass spectrometry (IRMS)-based method

will be done. the pis hypothesize that the formation and the strength of mode and intermediate waters have a strong influence on the lateral transport of anthropogenic carbon and thus the decadal variability of the water column anthropogenic carbon inventory change. as a result, the change in inventory has both meridional and zonal trends, and therefore a combination of a13.5 and a16s will better represent the basin-wide changes. two objectives will be achieved in testing this hypothesis: (1) demonstrate that precise and accurate  $\delta^{13}\text{C}$ -dic data, comparable in quality to irms-based data, can be collected via the crds-based method, and that large numbers of samples can be analyzed onboard ships and back home with high spatial resolution comparable to other go-ship level 1 parameters such as dic; (2) assess the spatial variations and temporal changes of the anthropogenic carbon uptake and storage rates in the south atlantic ocean. in particular, the pis will compare estimated anthropogenic carbon inventories independently from  $\delta^{13}\text{C}$ -dic and dic observations from transect a13.5 (2022 vs. 2010 and earlier data) in the eastern basin with those of transect a16s (2024 vs. 2013 and earlier data) in the western basin. they will also compare the basin-wide water column anthropogenic  $^{13}\text{C}$ -dic inventory with the surface ocean anthropogenic  $^{13}\text{CO}_2$  uptake flux estimated from air-sea carbon isotope disequilibrium, the difference being anthropogenic carbon carried by lateral transport. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: CAREER: Probing and Manipulating Electronic and Spin Degrees of Freedom in Paramagnetic Single Molecule Circuits

Awardee: Trustees of Boston University

Amount: \$701,995.00

Abstract: this award is funded in whole or in part under the american rescue plan act of 2021 (public law 117-2). with the support of the chemical structure, dynamics, and mechanisms a program in

the division of chemistry, dr. maria kamenetska of boston university is investigating the electronic and magnetic properties of single paramagnetic molecules wired into an electric circuit. the use of molecules as switches, transistors, or qubits could enable the development of smaller and more powerful electronic devices than what is currently available. of particular interest for this application are paramagnetic molecules, which have intrinsic magnetic properties, making them candidates for applications in non-volatile memory and in quantum information science. maria kamenetska and her group use an approach based on scanning tunneling microscopy to measure current through a single molecule bound to metal electrodes. these experimental measurements are complemented with computational investigations to elucidate how the chemical environment influences the electronic and magnetic properties of the resulting molecular circuits. understanding chemical interactions between the electrodes and paramagnetic molecule can improve circuit reliability, control, and functionality, with potential for magnetic sensing and gating in single molecule circuits. broader impacts focus on training a diverse and quantum-literate workforce at the interface of molecular science, electronics and quantum technology as well as building and improving the curriculum of and mentoring students in the newly-implemented chemistry and physics undergraduate major at boston university. this research aims to identify chemical design principles and nano-manipulation techniques for forming robust single paramagnetic molecule circuits and to investigate their emergent electronic and spin degrees of freedom. experimental approaches, such as inorganic synthesis and scanning tunneling microscope break junction (stmbj) single molecule conductance measurements are coupled with density functional theory (dft) and non-equilibrium green function (negf) computational techniques to achieve a comprehensive and iterative study of magnetically-functional single molecule circuits. three terminal electrical measurements are performed using an electrochemical stm configuration to reveal the effect of metal-molecule chemistry on electronic degrees of freedom of the junction, while stmbj measurements on ferromagnetic electrodes allow spin-resolved electron transport measurements. dft calculations support the experimental work and provide further insight into structure-property relationships in

metal-molecule junctions. the broader impacts focus on student training at the interface of molecular science, electronics and quantum technology. a newly developed chemistry and physics undergraduate major, that aims to promote **\*\*diversity\*\*** and inclusion, serves to create of an environment that encourages interdisciplinary science at an early career stage. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: RCN: LEAPS: Leveraging, Enhancing and Developing Biology (LED-BIO) Scientific Societies  
Shedding Light on Persistent Cultural Challenges

Awardee: American Society For Cell Biology

Amount: \$701,434.00

Abstract: each field in the sciences has historically been represented by its own scientific society, bringing together individual researchers for regular meetings where they can network, share discoveries, and collaborate. while it is rare for multiple distinct scientific societies to interact, they often perform similar functions, such as promoting the professional development of their members and promoting **\*\*diversity\*\*** among the next generation of researchers in their respective fields. this project will establish a collaborative network of experts to identify evidence-based inclusion strategies to accomplish the following: (1) collect consistent demographic data of society memberships, (2) better integrate scientists in transitional career stages into scientific society activities, and (3) diversify the ranks of scientific society leaders. by fulfilling these goals, this project aims to overcome persistent challenges that frequently undermine **\*\*diversity\*\*** efforts within independent communities of scientists and to broadly share this information for the benefit of all scientific communities. scientific societies predominantly approach **\*\*diversity\*\*** and inclusion efforts by supporting the professional development of individual members who are from historically underrepresented groups in stem. unfortunately, data is lacking to evaluate the efficacy of these

efforts, and additional approaches are likely to be required to address the systemic inequities underpinning skewed demographics among stem practitioners. fortunately, scientific societies that function as communities of practice (cops) are uniquely positioned to lead cultural change and promote inclusive environments to foster a diverse stem workforce. this research coordination network (rcn) project will use virtual town halls and in-person think tanks to expand and strengthen a cross-disciplinary network of cops. this network will collaborate to identify evidence-based strategies to address three persistent challenges that scientific societies face as identified by members of the alliance to catalyze change for equity in stem success (access): (1) lack of data to track scientific society membership demographic composition, (2) lack of integration of scientists in transitional stages of their careers into disciplinary cops, and (3) lack of **\*\*diversity\*\*** among highly visible thought leaders, including speakers in scientific programs. this rcn is coordinated by access and its member societies in the life sciences (the american society for biochemistry and molecular biology, the american society for cell biology, the american society for pharmaceutical and experimental therapeutics, the endocrine society, and the biophysical society), the quality education for minorities network, the marine biological laboratories at woods hole, and the nsf includes aspire alliance. the resulting strategies and standards will be reported and disseminated through open access training materials and publications. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Amount: \$700,000.00

Abstract: self-organization can be viewed as a phenomenon whereby unanticipated global

configurations and patterns of a collective emerge from fully distributed and simplistic rules performed by each individual, without any global coordination or external intervention. self-organization and emergent behavior arise naturally across many fields: distributed systems and swarm robotics in computer science, interacting particle systems in physics, population dynamics and flock coordination in biology, autonomous systems in robotics and control theory, and smart materials, to name a few. recently, the synergy between discrete probability, algorithms and statistical physics has provided a new approach for designing self-organizing particle systems by harnessing collective, emergent behavior of physical systems. the laws of physics play an increasingly important role in collective behavior at the nano- and micro-scales, especially since individual agents are far less capable than their macroscopic counterparts. yet, while the principles of statistical physics have motivated many experimental systems, little has been done to make the corresponding underlying distributed algorithms rigorous. this project investigates how to program collections of agents to perform tasks by modeling the dynamics as self-organizing particle systems performing steps of markov chains through local interactions that can be rigorously analyzed. the limiting distributions of these chains have distinct equilibrium characteristics that can be used to program collective behavior. the principal investigators take a three-pronged approach: first, they introduce and study generalizations of common statistical physics models, such as the potts, ising and hard-core models, to better capture the constraints imposed by micro-scale systems of interacting agents. next, they explore methods to better understand the nonequilibrium dynamics of these systems long before convergence and possibly subject to forces that make the markov chains nonreversible. finally, they explore how collective systems might be programmed through deliberate placement of obstacles and features in the environment, rather than programming the agents themselves, as many of these tiny agents are incapable of any sophisticated (traditional) computation. as an example of programming the environment, a new version of the schelling segregation model is being studied where people move with higher probabilities if they are unhappy with the local demographics of their neighborhoods, but these preferences can be somewhat

mitigated by the placement of desirable urban infrastructures that modify individuals' incentive structures and biases. the project is having impact in promoting and advancing interdisciplinary research across many fields; education, through advanced graduate courses and broad, interdisciplinary talks; **\*\*diversity\*\*** at the graduate, undergraduate, and faculty levels; outreach to the general public and for k-12 education; and municipal planning, through coordination with regional planning faculty and the city of atlanta. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Catalyzing Transformative Change in STEM Education through an Institute for Inclusive Pedagogy

Awardee: Massachusetts Bay Community College

Amount: \$699,994.00

Abstract: this project aims to serve the national interest by implementing an institutional change to broaden participation in stem fields. a series of three annual five-week stem summer institutes at massbay community college will aim to make significant, lasting, and positive changes in the way faculty teach students who identify as black, indigenous and/or people of color (bipoc). the project will train a total of thirty stem faculty and staff and include fifteen high school faculty from two regional high schools in the institution's catchment area as well. participants will learn how to better serve bipoc stem students. massbay faculty will be mentored through implementation of revised classroom practices during the academic year. this project will help to address the problem that massbay is retaining and graduating bipoc stem students at lower levels compared to their counterparts. the project will seek to impact faculty through professional development at massbay and at regional high schools, thereby contributing, over time, to an increase in the **\*\*diversity\*\*** of students in the stem pipeline and workforce. the goals of the project will be to (1) educate stem

faculty regarding bipoc needs; (2) connect stem faculty to resources to incorporate culturally inclusive pedagogy into their courses; (3) mentor those faculty; and (4) monitor faculty progress via professional, external evaluation. the method to be employed will be professional development that will emphasize culturally responsive pedagogy?pedagogy that requires faculty to understand how to incorporate multiple methods of instruction that are based on students? life experiences and backgrounds. the project will focus on systemic institutional change in attitudes toward teaching bipoc students that will be measured at the departmental and institutional levels, and across communities of stem educators and/or educational researchers. as a result, over time, massbay will recruit, support, and graduate more bipoc students. the nsf iuse: ehr program supports research and development projects to improve the effectiveness of stem education for all students. through the institutional and community transformation track, the program supports efforts to transform and improve stem education across institutions of higher education and disciplinary communities. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Toward an integrated modeling framework for physics-based estimates of megathrust rupture potential

Awardee: University of California-San Diego Scripps Inst of Oceanography

Amount: \$698,099.00

Abstract: subduction zones, where tectonic plates are recycled back into the mantle as in the cascadia margin of the pacific northwest of the united states, host the largest earthquakes and give rise to significant hazard through ground shaking, landslides, and tsunamis. this project seeks to better utilize existing geophysical and geological observations from important ?natural laboratories? (cascadia, japan and new zealand) by merging them more fully into new, comparative computer models of system behavior. developing new modeling software and integrating constraints is

expected to lead to new insights into the physics of subduction zone earthquakes, what observations imply for future earthquakes, and, importantly, which observations are needed to improve our understanding of subduction zone hazards and how to reduce uncertainties about system behavior. the project will involve international collaborations, leverage past investments, and will contribute to defining future, optimal observational strategies. an interdisciplinary workforce of students and post-docs will be trained through research and educational efforts, and all project software, tutorials and ?cookbooks? for subduction earthquake modeling will be shared with the community, contributing to advancing computational geoscience approaches in general. a program for precollege, undergrad, and early grad students will be developed to emphasize computational geoscience as an avenue to enhance **\*\*diversity\*\*** in the geosciences. this collaborative effort seeks to integrate seismological, geodetic, experimental, and geological constraints for the japan, new zealand and japan natural subduction zone laboratories into numerical models to advance our understanding of megathrust earthquakes. forward models and a new numerical modeling framework for data assimilation will be deployed to get closer to versatile tools for data-driven, physics-based hazard assessment. the focus is on the evolution of fault stress and strength over a range of spatio-temporal scales, quantifying uncertainties and sensitivity to parameters. this will allow formulating best strategies for inferring relevant parameters from data in the presence of ambiguous physics, including optimal observational design within the ongoing sz4d community effort. all code will be made publicly available along with cookbooks and tutorials, and a networked effort will establish new, quantitative links and leverage individual efforts greatly. fres funding will support a growing community of solid earth geodynamicists who want to deploy their models in a hazard and monitoring context. a focus will be on training and sharing material for interdisciplinary computational geoscience efforts, from undergraduate to post-doc and practitioner level. project participants will develop sustainable pathways for participation and work to enhance representation and inclusion in the geosciences by providing new pathways of entry based on modeling and remote sensing to complement field-based approaches. this award reflects nsf's statutory mission and has

been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Preparing Secondary STEM Teachers to Improve STEM Learning in High-need Schools by Applying Restorative Justice in Education

Awardee: Eastern Mennonite University

Amount: \$690,061.00

Abstract: this project aims to serve the national need to increase the number and **\*\*diversity\*\*** of highly effective stem teachers in high-need school districts. to address this need, the project will recruit, prepare, graduate, place, and support 24 stem majors to become secondary mathematics and science teachers. these stem majors will earn bachelor's degrees in biology, chemistry, computer science, or mathematics and be eligible to earn secondary teaching certification in one of these disciplines. an innovative aspect of the project is its focus on restorative justice in education, which can transform school climate by building relationships that support student learning, success, and identity in stem. the project will build upon strengths at the institution, including expanded recruitment activities to increase the number of diverse stem teaching candidates, teaching opportunities/field experiences in high-need schools, mentoring and peer relationships, and new in-service teacher supports. this project at eastern mennonite university includes a partnership with harrisonburg city public schools. project goals include implementing restorative justice in education across diverse school settings, improving learning outcomes and teacher retention in local school communities, and providing an innovative, replicable model for teacher preparation. increased collaboration with the partnering school district will prepare qualified stem teachers, add meaningful supports for new teacher retention, and strengthen restorative justice in education professional development. project objectives include to: 1) recruit, support, and graduate 24 biology, chemistry, computer science, and mathematics majors with secondary education certification; 2)

engage the project's pre-service stem teachers in training about restorative justice in education, as well as in mentoring relationships and field experiences; 3) place and retain the project's graduating pre-service stem teachers in high-need school districts; 4) institutionalize and sustain successful elements of the project; and 5) study the impact of integrating restorative justice in education into the curriculum for pre-service and professional development of in-service stem teachers in high-need school districts. new knowledge will be generated through investigating two research questions: 1) to what extent and in what ways does a restorative justice-infused curriculum help pre-service and early-career stem teachers feel prepared to meet the challenges associated with teaching in culturally and linguistically diverse school settings? and 2) which project elements are associated with the development of one or more aspects of equitable practice? external evaluation will provide formative feedback for continuous improvement during implementation, and project results and lessons learned will be shared with the community so that effective methods and practices can be replicated at similar institutions and teacher training programs. this track 1: scholarships and stipends project is supported through the robert noyce teacher scholarship program (noyce). the noyce program supports talented stem undergraduate majors and professionals to become effective k-12 stem teachers and experienced, exemplary k-12 teachers to become stem master teachers in high-need school districts. it also supports research on the persistence, retention, and effectiveness of k-12 stem teachers in high-need school districts. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Trade-offs, limits to adaptation, and multiple solutions: rules elucidated by selective breeding for high activity levels

Awardee: University of California-Riverside

Amount: \$687,489.00

Abstract: this project focuses on understanding how organisms make trade-offs in energy allocation to different activities and how multiple solutions to enhance locomotor activity may evolve. biological **diversity** encompasses not only numbers of species but the functional **diversity** that they exhibit. organisms work in a variety of ways, and often exhibit trade-offs and multiple solutions. one example of a trade-off is the negative relationship between the number of offspring produced and the size of individual offspring, as documented in many groups of plants and animals. this trade-off is often attributed to a constraint on the total amount of energy available for reproduction. multiple solutions are apparent in the various ways that flight has evolved (e.g., birds versus bats). this research project addresses both of these phenomena in the context of a novel experiment that involves selective breeding for high voluntary levels of exercise in house mice. two hypotheses will be tested: (1) selection for high activity is associated with reductions in lifetime reproductive success, representing a trade-off between locomotor activity and fitness, and (2) the trade-off between average running speed and duration that has evolved among the high-activity mouse lines is reflected in corresponding differences in characteristics of their muscle tissues. the project will help to elucidate the fundamental nature of bio**diversity**. the results will be disseminated in scientific publications and wikipedia pages will be created and updated. an online open educational resource version of ecological and evolutionary physiology, an undergraduate course, will be developed. this project will involve training for both graduate students and undergraduates in a collaborative, integrative, and cross-disciplinary research setting. to increase participation and **diversity**, students from underrepresented groups and educationally or economically disadvantaged backgrounds will be recruited. trade-offs and multiple solutions are inherent to life and appear to underlie a substantial amount of the variation in bio**diversity** over time. however, few studies have used experimental evolution to address these topics. the proposed research will use selection for high locomotor activity, in a model organism (laboratory house mice), to elucidate trade-offs and multiple solutions during locomotor evolution. because locomotor activity is a key component of the life history of animals, results of these studies should provide insight into general

principles. the research will take advantage of a unique resource comprising four replicate lines of high runner mice that have been selectively bred for more than 90 generations for voluntary locomotor activity, and an additional four lines that serve as non-selected controls. aim 1 will test for reduced lifetime reproductive success in the selected lines and whether this trade-off manifests in different ways in the replicate lines (e.g., reduced litter size vs. reduced length of reproductive lifespan). aim 2 will test whether trade-offs in muscle function underlie the trade-off between average running speed and duration that has evolved among the four selected lines, and if multiple solutions at the level of muscle performance are involved. the mouse lines will be made available to other researchers, and the online course materials and wikipedia content to be developed will be broadly disseminated. several undergraduate and graduate students, recruited from groups traditionally under-represented in science, will participate in the research. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Discovery and Design with the FAST Principle: Following Local Models of Stability to Emergent Phenomena in Intermetallic Structures

Awardee: University of Wisconsin-Madison

Amount: \$685,579.00

Abstract: non-technical summary: the role played by metallic materials in the advancement of prosperity and national security is evolving. research in these materials has increasingly shifted from mechanical properties, conductivity, and corrosion resistance to more exotic effects related to the quantum nature of electrons, such as the resistance-free conduction of electric currents, advanced magnetic phenomena, and the conversion of thermal energy into electric energy. underlying these properties is a startling **\*\*diversity\*\*** in the geometrical arrangements that the atoms of materials can form at the microscopic level. understanding and learning how to control these

arrangements is a limiting factor in the design of new metallic materials. this project is promoting the progress of science by building a predictive model for how different types of interactions between neighboring atoms in a metal propagate to form the observed complex atomic arrangements, opening avenues to the discovery of new materials. theoretical calculations are being used to analyze these interactions and explore their implications, while databases of structural information are scanned to identify metallic materials in which intriguing behavior at the atomic level are expected. the predictions of theory are guiding experimental investigations of new metallic compounds, which provide feedback on the models being developed. this project also impacts the training and education in the stem fields, with an emphasis on solid state chemistry. new content is being created for the science through comics website, which uses relatable analogies and humor to inspire interest in science. in addition, the free on-line textbook interactive solid state chemistry is being developed for dissemination to a broad range of students and educators in collaboration with libretexts. here, comics introducing the materials are integrated with interactive tools for active student engagement, such as structure models that can be manipulated in three dimensions. the research team is also increasing the participation of members of underrepresented groups in the sciences through outreach activities and mentoring.

technical summary: intermetallic phases are a rich source of potential functional materials, as they combine an unparalleled structural **\*\*diversity\*\*** with valuable physical properties. to fully realize this promise, however, design principles are still needed for guiding the crystal structures of these phases, such that their structure-properties relationships can be systematically investigated, and materials with structures tailored to specific applications can be prepared. in this project, the need for such design principles is being addressed through the development of the predictive capabilities of the frustrated and allowed structural transitions (fast) approach. of the many transformations or modifications a structure could potentially undergo, those that involve cooperation between the various factors influencing stability can be expected to out-compete energetically those in which the factors conflict with each other. in one component of this work, the scope of the fast approach is being expanded

through the computer-aided screening of crystal structure databases for geometrical features associated with easy transitions, yielding candidate structures for theoretical analysis and experimental investigation. simultaneously, the completeness of the fast picture is tested and improved through its application to the structural preferences involving 18-n+m isomerism in transition metal-main group intermetallics, in which a variety of bonding configurations are used by different compounds to adhere to the 18-n electron counting rule for any given electron count. finally, the predictive implications of the fast schemes are explored by translating these pictures into force field models for large-scale molecular dynamics simulations. predictions of emergent structural properties, such as incommensurate modulations or phase transitions, are pursued experimentally. in all of these endeavors, the experimental results are being used to refine the theoretical and conceptual approach. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: CSBR: Rehousing of the Mammal Collection at the University of Kansas Biodiversity Institute

Awardee: University of Kansas Center for Research Inc

Amount: \$682,711.00

Abstract: this project ensures the long-term preservation and security of the mammalian research collections housed at the university of kansas (ku) bio\*\*diversity\*\* institute. the ku bio\*\*diversity\*\* institute?s mammal collection is of international importance, ranked as the sixth largest in north america, and the third largest university holding in the world. this project replaces antiquated wooden specimen cabinets with updated stainless steel casing to rescue irreplaceable specimens from environmentally deficient conditions and preserve them in ideal, climate-controlled, pest-free housing in perpetuity. safeguarding the ku bio\*\*diversity\*\* institute?s mammal collection ensures the continued contribution of these resources to bio\*\*diversity\*\* science, formal undergraduate and

graduate education, and public programming for K-12 students, teachers, and public audiences of the KU Biodiversity Institute's Natural History Museum. This project engages several undergraduate and graduate students in collections-based research projects and active curation. The physical specimens preserved at the Biodiversity Institute provide a critical foundation for research and education on DNA, climate change, evolution, conservation, and emerging pathogens, and are available for loan by researchers across the globe. The KU Biodiversity Institute's mammal collection houses 279,936 dry specimens in 332 cabinets, 185 of which are antiquated and compromised wooden cabinets that date to the 1950s and 1960s, and whose joints, doors, and seals are inadequate for protecting dry specimens from pest infestations. Specimens will be vacuumed and frozen at -40°C for 2 weeks to eliminate pests, then transferred to stainless steel cases for long-term preservation. During the transfer, data from specimen tags will be verified and digitally recorded in the Specify Museum database, and served to the community through GBIF, iDigBio, BiSON, and VertNet. As specimens are processed, phenotypic characters will be recorded, including the reproductive status or molting progress of each specimen, and these data will be used to test for shifts in mammalian life history events over time. Students will collaborate with Exhibits staff at the KU Biodiversity Institute to conceive and build a new public exhibit focused on the importance of scientific collections. The exhibit will highlight research stories that illustrate how critical collections are for solving problems of societal interest, including recognizing emerging pathogens and tracing the origins of invasive species. This award reflects NSF's statutory mission and has been deemed worthy of support through evaluation using the Foundation's intellectual merit and broader impacts review criteria.

Title: How do multiple coastal stressors structure the genomic diversity of marine populations?

Awardee: University of Rhode Island

Amount: \$680,897.00

Abstract: marine species face a complex suite of stressors that span multiple temporal and spatial scales from long-term global ocean change to localized episodes of coastal acidification. the cumulative and concurrent impacts of multiple stressors remain relatively unknown and requires investigating their synergistic impacts across all life stages. two common stressors in coastal environments are hypoxia, or low dissolved oxygen, and coastal acidification. hypoxia and coastal acidification are linked to daily cycles of respiration and photosynthesis, even in pristine bays and estuaries. coastal waters are also affected by pulses of natural and artificial freshwater runoff driven by rainfall and storm events. pulses of freshwater can cause short-term, low salinity conditions, another stressor, that are expected to worsen with climate change. for many marine species, larval stages are the only means of migration and genetic exchange, and larvae are likely encountering hypoxia, coastal acidification, and low salinity stressors while they are in shallow coastal waters. additionally, early juveniles may encounter extended periods of all three stressors. the interaction of early life-history stages with repeated and combinations of coastal stressors has the potential to result in an increase of larval/juvenile mortality or the removal of less tolerant larvae. the consequences of this differential mortality are being investigated in the eastern oyster using laboratory multi-stressor exposure experiments and in the field through genomic surveys of natural populations. patterns of genetic selection are being analyzed by combining genomic and environmental data to elucidate how multiple stressors are shaping marine populations. broader impacts include training opportunities for a post-doctoral fellow, graduate and undergraduate students and societal impacts. results from the study are key to predicting how oyster reefs will adapt to long-term climate change and human population growth. a symposium is planned to bring scientists and members of the broader community together to discuss conservation and restoration of oyster reefs and sustainable aquaculture. a better understanding the physiological limits of larvae and juveniles to stressors is contributing to new strategies for oyster hatcheries to optimize selection and screening of brood stock for robust larvae and juveniles. the broad goal is to characterize how hypoxia (do), coastal acidification (ca), and low salinity events (ls) shape population connectivity and

microevolutionary processes of marine invertebrates. as larvae grow and develop, they may be able to tolerate short-term exposures to environmental stressors, but prolonged exposure to diurnal do/ca cycling and ls events may reduce subsequent survival, especially in juveniles. larval and juvenile interactions with multiple stressors have the potential to either disrupt gene flow by simply not allowing migrant exchange or to act as a selective force, structuring populations through genotype-environment interactions. this project uses a coupled experimental and seascape genomics approach to investigate how multiple stressors are shaping observed genomic **diversity**. phase 1 is determining how larval and juvenile genotypes and phenotypes respond to multiple stressors across different developmental time points. experiments include two larval short-term exposures to factorial combinations of do/ca and ls, and a long-term juvenile exposure to factorial combinations of do/ca diurnal cycling and ls. the coding regions of genes expressed during experimental exposures are being sequenced using a cost-effective exome capture method. phase 2 is determining the role of natural and anthropogenic forces shaping the evolution of oyster populations by testing if selective regimes differ and interact across life-history stages and if the frequencies of both neutral and resistant genotypes correlate with environmental conditions. surveys of the genomes of adult populations across multiple localities from several urbanized estuaries are generating a seascape genomic framework based on a panel of genomic markers, including potential loci under selection during early-life history. these data are being integrated with environmental data to elucidate the mix of factors that contribute to population structure and local genetic **diversity**. results are linking adult genotype frequencies at both neutral and putatively selective loci to changes in allele frequencies in response to early larval, late larval, and early juvenile exposure to stressors. the research is unraveling the complex interaction of selection, migration, and drift on marine genetic **diversity** for a mechanistic understanding of the genomic consequences of coastal stressor and their interaction on larvae. this project is jointly funded by biological oceanography and integrative organismal systems. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's

intellectual merit and broader impacts review criteria.

Title: CAREER: Redefining the high field strength element systematics of subduction systems using non-traditional stable isotopes

Awardee: University of Arizona

Amount: \$679,590.00

Abstract: reconstructing the nature of the geologic processes responsible for the evolution of our planet, including when and how continents formed and plate-tectonic cycles were established, has been a long-standing goal of earth scientists. clues for answering these questions are "coded" into the geochemistry of the ancient rock and mineral record, but interpreting these geochemical signatures is not always straightforward. over billion-year timescales, the rocks that constitute earth's continents have been deformed and overprinted by younger geologic processes, significantly obscuring their original structural and chemical characteristics. in order to "see through" this complex evolution, geoscientists use chemical signatures retained by elements that are not easily altered and/or remobilized, and thus that can provide clues into primary rock-forming processes despite subsequent overprinting. a group of elements particularly suited for these investigations are the so-called high-field strength elements (hfse), a group of transition metals with unique geochemical characteristics which make them not only important to understand crust formation but also very resilient to alteration. in particular, the isotopic compositions of these elements, which can now be measured with great accuracy and precision, can provide unique glimpses into the geochemical processes taking place in convergent tectonic margins and during formation of continental crust. nevertheless, making geologically meaningful interpretations from these data requires a robust understanding of the processes that control the observed isotopic signatures, and developing such framework is the central research goal this project will undertake. this career project will leverage recent analytical developments in the field of non-traditional stable

isotopes to i) conduct a detailed study of the mass-dependent isotope fractionations that characterize the hfse titanium, zirconium, and hafnium in subduction environments; and ii) utilize these isotopic variations for better understanding the processes leading to their fractionation and fluxes during formation of continental crust. to achieve this, the research team will generate a series of combined ti-zr-hf isotopic datasets from key geologic components and petrologic processes characterizing the "subduction factory" and that are known to influence the chemistry of arc-related magmatic systems. isotopic fractionations at the bulk-rock and mineral scales will be determined in various global localities of orogenic peridotites, mid ocean ridge basalts, high-pressure/low-temperature subduction complexes, lower-crustal arc cumulates, and arc-related basalts and differentiated volcanic rocks, to understand hfse mass-transfer and isotopic fractionations across the entire subduction cycle. samples will be measured using high-accuracy methods involving calibrated double-spikes and mc-icp-ms measurements. in addition to the broader scientific impacts that will result from this research, the pi will develop educational activities that foster greater equity, "diversity", and inclusivity within the geosciences starting from a pre-college stage. these include the development of an afterschool bilingual program for hispanic/latinx high-school students in collaboration with the tucson unified school district (tUSD), active recruitment of urm undergraduates into meaningful research experiences, and training of diverse graduate students and postdocs. as a result of this project, the pi will also develop an accessible on-line resource for researchers and students interested in learning more about non-traditional stable isotopes, constructed with active student involvement. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Effects of top scavenger declines?from microbes to ecosystems

Awardee: Regents of the University of Idaho

Amount: \$677,575.00

Abstract: unless first consumed by a predator, all animals enter the carrion pool when they die. scavengers and microorganisms play a critical role in returning carcass-derived nutrients to the soil where they get recycled and used for plant uptake and growth. the impact of carrion inputs on nutrient cycling, food web dynamics, and ecosystem carbon balance remains a mystery. with global declines of many species including scavengers, it is essential to quantify how the quantity and quality of carrion-derived nutrients shapes plant community structure and ecosystem dynamics. tasmanian devils are an ideal and charismatic species with which to study the effects of scavenging on ecosystem processes. they are one of a few carnivores worldwide that consume bones. by accelerating the cycling of key plant growth-limiting nutrients that would otherwise remain locked in bone material for years, tasmanian devils provide a critical ecosystem function. in recent years, the emergence of a highly transmissible cancer ? devil facial tumor disease, or dftd ? has dramatically reduced devil population sizes in eastern tasmania and has spread throughout the island, threatening this iconic species with extinction. researchers will use this tragic situation to test whether devil-scavenging impacts can be detected on an ecosystem scale and how devil population declines result in a shift in the role of other scavenger species. this project will provide training opportunities for us graduate students and post-doctoral scholars in an international setting. through education and outreach activities, researchers will highlight the linkages that exist between scavengers, bio\*\*diversity\*\*, and ecosystem resiliency. few studies have directly investigated the effects of non-plant inputs on energy transfer within food web networks. as a result, there is a considerable knowledge gap in understanding how carrion and scavenger guilds govern biogeochemical cycling at an ecosystem scale. in tasmania, the east to west spread of dftd, a lethal, transmissible cancer, threatens devils with extinction and has created a population density gradient across the island (from 0% to 100% of carrying capacity). the resulting 'natural experiment' offers a rare opportunity to study how apex scavenger declines alter energy transfer within food webs and nutrient flows through carrion, soils, and plants. high-frequency monitoring and sampling stations will

be established at five study sites that span the dftd gradient and capture four experimental treatments: (1) full scavenger access (staked prey carcass); (2) devil exclusion (fenced prey carcass allowing access to all scavengers but devils); (3) reconstructed devil latrines to capture nutrient pulses from localized scat; (4) and soil-only controls to monitor background c and nutrient availability. devil and mesopredator densities at carcasses will be estimated using camera arrays; invertebrate densities will be assessed using appropriate insect traps. stable isotope tracing will be used to track how carcass-derived nutrients influence microbial community **\*\*diversity\*\*** and soil carbon formation. plant productivity (npp), leaf quality, seedling recruitment, and fine root biomass will be estimated at each site and across the continental dftd gradient. using temporal and spatial variation in the extent and timing of devil population declines, a series of scaled experiments will be used to: (1) determine how variation in scavenger densities affects local soil biogeochemistry; (2) investigate how carrion and scavenging networks induce shifts in the metabolic efficiency of microbial communities and decomposition rates of new plant litter inputs; (3) test the scale at which scavenging by devils is detectable; and (4) integrate findings from field and laboratory experiments to predict how bio**\*\*diversity\*\*** loss will affect ecosystem function over the next 50 years. the project will support a team led by an early-career female scientist, involve international collaboration and provide training at the graduate student and postdoctoral levels. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: How and when did the Mongolian Altai (de-)form? Implications for intracontinental deformation

Awardee: New Mexico Institute of Mining and Technology

Amount: \$676,882.00

Abstract: the mongolian altai are an approximately 2000 km-long mountain range in western

mongolia that are part of a vast mountainous region in central asia referred to as the central asian orogenic belt. understanding how a mountain system that is located >1000 km from a modern tectonic plate boundary originally formed is important as the altai play an important role in regulating asian climate and bio\*\*diversity\*\* and in controlling the distribution and reorganization of earth materials through erosion and sediment transport. this study will test how the earth's crust deforms into mountains in the middle of tectonic plates rather than at the edges. the pis will use thermochronology (the study of mineral cooling histories) to measure the timing of mountain development and conduct field-based studies of sedimentary rocks to study changes in erosion and deposition patterns caused by mountain uplift. these results will be compared to numerical models testing different ways to form mountains in the middle of tectonic plates. this research will provide important societal outcomes by 1) supporting the training of graduate and undergraduate students in stem fields including minority and underrepresented students at a hispanic serving institution, 2) increasing participation of women in stem as both principal investigators and graduate students within this project, 3) increasing public scientific literacy through undergraduate education and education outreach, 4) developing partnerships between american and mongolian scientists, and 5) the development of online interactive field tours for undergraduate education. recent large-scale, interdisciplinary projects have led to major advances in our understanding of the rates, relative timing, and periodicity of tectonic plate margin processes that define orographic landscapes. however, our understanding of plate interior orogenesis is less evolved, as intracontinental orogens defy models of orogenesis as a plate-boundary driven process. the mongolian altai are part of one of the largest intracontinental orogenic systems?the central asian orogenic belt, and yet limited data exist to explain the origin of this mountain system. this project will test specific models of intracontinental orogenesis in the mongolia altai, each of which predict a different timing, rate, and style of uplift. this research will integrate bedrock and detrital thermochronology, sedimentology and basin analysis, and geomechanical modeling to document the timing of onset of intracontinental orogenesis in the mongolian altai; understand fundamental (rheological, geodynamic, inherited)

controls on the formation of an orographic landscape in this region; and to understand the possible conditions that produce intracontinental deformation from plate boundary forces and the timescales on which this deformation occurs. these outcomes will allow testing of whether the mongolian altai are relict topography from a mesozoic suture zone, are a geodynamic feature of isostatic or dynamic processes, or formed due to localized deformation from cenozoic plate boundary stresses. field and analytical data will provide direct observations to test these hypotheses that can be further constrained by numerical models that interrogate the geomechanical plausibility of these processes. this study will not only provide the first basement thermochronologic dataset from a ~800 km along strike zone within the mongolian altai and the first detrital thermochronologic dataset from the entire altai system (2000 km strike length), but will integrate this dataset with work in contemporaneous sedimentary basins and geomechanical modeling to put these data in a well-constrained geologic context. the proposed research will also improve our understanding of what processes drive formation of intracontinental orogens globally, a major outstanding question in the field of tectonics.

this project is jointly funded by the tectonics program in the division of earth sciences and the established program to stimulate competitive research (epscor). this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: CAREER: Sea Level and Topographic Evolution (SLATE): Exploring the feedback between sea level and sediment redistribution

Awardee: University of Wisconsin-Madison

Amount: \$676,866.00

Abstract: sea-level changes are of wide interest because they affect flood hazards, reorganize coastlines, influence volcanic eruptions, and reflect changes in climate. the proposed work will remove a barrier for understanding sea-level change by developing a new model that captures the

effects that sediment redistribution and sea-level change have on one another. this will provide a new tool for understanding the controls on sea-level change and flood hazards near large rivers, which are home to many coastal cities, of relevance to nsf's coastlines and people (cope) initiative. these efforts will be paired with four education and outreach tasks focused on sea-level change, including the development of a new university course on sea-level change, training of students in pedagogy and mentorship, public outreach through the university of wisconsin geology museum, and a five-year outreach program to k-12 students from underrepresented groups in stem. the goal of this project is to improve our understanding of the feedback between sea level and sediment redistribution. although it has long been known that sea level and sediment redistribution influence one another, the quantitative strength of this feedback remains a matter of contention. the proposed work is aimed at closing this knowledge gap through the development of a novel model that couples earth's topographic evolution to sea-level change. this will be used to explore the controls on the sediment-sea level feedback by quantifying the sensitivity of sea-level changes to marine sediment transport, the sensitivity of lowland rivers to sea-level change, and the effects of sediment redistribution on estimates of global mean sea level and global ice volume at the last interglacial period, an analogue for modern climate. this will clarify the sensitivity of sea-level change to sediment erosion and deposition—a common feature of earth's coasts—and provide a basis for improving projections of future sea-level change. this will support education, outreach, and **\*\*diversity\*\*** initiatives through the training of two phds students, the mentoring of undergraduate students, and a new five-year outreach program with k-12 students from underrepresented groups in stem. the project is co-funded by the geomorphology and land-use dynamics program and the marine geology and geophysics program. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: CAREER: Tunable Graphene Microelectrodes for Real-time Biological Sensing

Awardee: University of Cincinnati Main Campus

Amount: \$675,001.00

Abstract: this award is funded in whole or in part under the american rescue plan act of 2021 (public law 117-2). with the support of the chemical measurement and imaging (cmi) program in the division of chemistry, ashley ross of the university of cincinnati is studying how graphene, a single layer of carbon atoms arranged in a two-dimensional honeycomb lattice, can be used to sense neurochemicals. by controlling the direction of the carbon atoms in the honeycomb and placing different kinds of atoms on the surface of the graphene, dr. ross and their research team will work toward making electrodes that can electrically communicate in an effective way with chemicals that are key to understanding the nervous system. this new approach with graphene electrodes offers the possibility of systematically studying how tuning the orientation of the honeycomb edge and the surface chemistry of graphene can be used to make electrodes capable of sensing neurochemicals better than methods known for 40 years. such tunable electrodes are expected to offer extremely rapid sensing of changes in the amounts of neurochemicals within very tiny areas of the body, which would be very valuable to understanding the way messages are sent and received by the nervous system. this new route to making tailored and rapid sensing of neurochemicals may shed light on the way in which a variety of cells are given and receive instructions to initiate, stop, or regulate biological responses. importantly, the new graphene fiber electrodes have the potential to give a

glimpse into the immune response and its programming by neurochemicals, by detecting fast changes in their amounts in whole organs. the project is anticipated to have a long-term impact on sensing by providing new measurement tools and an understanding of how the surface of the electrode and the structure of neurochemicals influence their detection. the impact of the project is to be broadened by building on an on-line discussion platform and seminar series, titled "analytical chemistry \*\*diversity\*\* colloquium?", to increase engagement and to nationally promote the work of underrepresented scientists in analytical chemistry. in addition, this project will develop multidisciplinary and discussion-based modules to be incorporated into courses to improve scientific literacy, create an environment of inclusion, and excite students from diverse backgrounds about analytical chemistry. there is a current knowledge gap in electrochemical sensing about enabling correlation and prediction of how changes in electrode structure and chemistry impacts the interface between solution-phase analytes having different structures and the electrode surface. the ability to precisely control and correlate how specific chemical and structural properties of the electrode impact detection of electroactive biomolecules will significantly influence our understanding of electrode-analyte interactions to enable exquisitely designed electrode surfaces for improved real-time biological sensing. in this project, we will advance knowledge of analyte-electrode interactions with fast-scan cyclic voltammetry because it is the primary electrochemical method used to probe real-time neurochemical signaling; therefore, this approach will have a major impact on dynamic neurochemical sensing. this project will focus on synthesizing and characterizing tunable graphene fiber microelectrodes to measure how carbon surface orientation and alignment, functionalization, surface energy, and three-dimensional structure impact electrochemical detection of neurochemicals. this proposal will ultimately enable expansion of real-time neurochemical sensing to beyond the brain to study nervous system regulation of immunity, communication along the gut-brain axis, and more, by providing significantly improved electrodes that enable ultra-sensitive and high-temporal-resolution measurements. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's

intellectual merit and broader impacts review criteria.

Title: CAREER: Engineering Interacting Photons in Superconducting-Circuit Lattices

Awardee: University of Maryland, College Park

Amount: \$675,000.00

Abstract: photons are particles of light which exist all across the electromagnetic spectrum, from radio and microwaves to visible and ultra-violet light. by making use of superconductors, which carry current without generating heat when cooled to very low temperatures, it is possible to make microwave circuits where, unlike in most room-temperature devices, the photons live for very long times and stay confined in small regions in space. since these photons stay put instead of flying away, they become more like conventional particles such as electrons, and the full might and **\*\*diversity\*\*** of microwave engineering can be used to control how they see and interact with the world. by controlling how these photons interact with each other and the world around them, this project will probe the fundamental building blocks of the materials around us and learn about how the environment in which a particle lives affects its properties. the project will also build upon the recently-initiated virtual amo seminar, of which the pi is a board member, to develop an auxiliary small-group program series aimed at engaging non-physicists and undergraduate students in online research seminars in a meaningful way and facilitating communication in the ever-broadening quantum workforce. among this project's specific research goals is to harness arrays of superconducting microwave resonators to produce microwave metamaterials in which photon-photon interactions can be mediated by superconducting qubits. building on previous theoretical work showing that these metamaterials can access unconventional band structures, such as lattices with gapped flat bands and also much more general mathematical objects such as tree-like and hyperbolic graphs, the pi will implement unconventional microwave lattices and incorporate qubits to mediate interactions. investigation will begin with one-dimensional lattices and

move toward higher-dimensional structures during the course of the project. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Sentinels: A plug-and-play RNA sensing technology platform for surveillance and response to emerging viral diseases

Awardee: William Marsh Rice University

Amount: \$673,890.00

Abstract: cells can be programmed to sense infectious agents and, in response, actuate biomolecular programs to alert, protect the host, or destroy the pathogenic target. engineering cells in this manner would provide a transformative approach to address the threat of emerging viral diseases. the goal of this project is to develop a novel pathogen detection platform that can be easily reprogrammed to sense new threats, and in response, produce any protein output. this technology will forward our ability to engineer sentinel cells for diverse diagnostics and therapeutic applications. this project will also provide educational and training opportunities aimed at increasing the number and **\*\*diversity\*\*** of high school students and undergraduates pursuing careers in biomolecular and cellular engineering, and related stem fields. as part of this project open-source web-based design tools for designing sentinel cells will be created through a student-led initiative. rna-based sensors present a particularly attractive option for programming cells to detect pathogens because they rely on designable rna base pairing interactions and enable detection of rna encoded genomes (genotypes) and mrnas (phenotypes) of both the pathogen and host, allowing for potentially more accurate readouts of the infection status. however, there is currently a lack of genetically-encoded rna detection platforms that can interface rna inputs to biomolecular outputs,

precluding the design of cellular devices that execute sentinel programs in response to specific rna signatures. to address this, biomolecular and synthetic biology strategies to create plug-and-play rna sense-and-respond platforms will be explored. devices will be created that detect different virus associated rna molecules, and, in response, activate diverse biomolecular programs to alert and destroy viruses. this will find direct applications for sentinel cell design and could be easily utilized for other applications in basic science, synthetic biology, and metabolic engineering. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Excellence in Research: Effect of Hydration on the Thermo-elastic Properties of Mantle Minerals and the Geophysical Implications.

Awardee: Delaware State University

Amount: \$672,584.00

Abstract: earth's deep interior is not accessible to direct sampling. as temperature and pressure increase with depth, man-made instruments become unusable. the most direct observations arise from studying vibrations generated by earthquakes, called seismic waves. the waves travel within the earth and are collected at the surface using seismographs. the seismic signal is analyzed to inform the structure and composition of earth's interior, as sonography is used in medical imaging. the velocity of seismic waves depends on the type of rocks they encounter. seismological studies combined with experimentation allow identifying rocks in the earth's mantle. it was shown that at depths of 410 to 660 km (255 to 410 miles) - in the so-called transition zone - two dense minerals are present: wadsleyite and ringwoodite. these minerals can incorporate large amount of water in their structure under the form of oh molecules (hydroxyls). the transition zone may contain as much water as that contained in the oceans. this has implications for earth's mantle thermal convection, which drives plate tectonics. yet, it is unclear how much water is stored in the transition zone. this is

partly due to uncertainties on how hydroxyls affect seismic-wave propagation in minerals. here, the researchers investigate how water incorporation in wadsleyite and ringwoodite affects the velocity of seismic waves. they synthesize in the laboratory minerals with various compositions and water contents. they carry out ultrasonic measurements at the extreme pressures and temperatures prevailing in the earth. these experiments are performed at a national synchrotron facility, to ensure specimen quality and measure their size by radiography during the measurements. the study outcomes are critical to better understand the properties of the transition zone. it has implications for the understanding of thermal convection in the earth. this project promotes multidisciplinary collaborations across earth sciences, physics, chemistry, and mathematics. it provides support for a post-doctoral associate and training for undergraduate students at delaware state university (dsu). dsu is a historically black university and a predominantly undergraduate institution. the project offers unique opportunities to students from groups underrepresented in science. it fosters **diversity** and inclusion in geosciences. it is co-funded by nsf directorate for geosciences and historically black colleges and universities - excellence in research (hbcu-eir) program. experimental and theoretical studies indicate that wadsleyite and ringwoodite can incorporate up to 2-3 weight percent of hydroxyl (oh-) in their structures. up to 1.5 weight percent of water was measured in a ringwoodite crystal trapped in a diamond which originated from the transition zone. water incorporation strongly affects mineral physical and chemical properties ? such as electrical and thermal conductivity, melting and flow ? as well as elastic wave propagation. here, the researchers synthesize polycrystalline samples of wadsleyite and ringwoodite containing controlled structural water. they use the 2000-ton uniaxial split-cylinder apparatus at stony brook university. the quality of the hot-pressed specimens is verified using x-ray diffraction, scanning transmission electron microscopy, bulk density measurements, and bench-top acoustic velocity measurements. specimen elastic wave velocities is then quantified by ultrasonic measurements at high pressure and temperature, in the mineral stability fields. these measurements are carried out at the 6-b-mb beamline of the advanced photon source (argonne national laboratory). the beamline is equipped

with a cubic anvil high-pressure apparatus coupled with in situ ultrasonic interferometry, x-ray diffraction and imaging. specimen water content is measured before and after the high-pressure experiments by infrared spectroscopy, secondary ion mass spectrometry, and using the electron probe micro-analyzer techniques. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: CAREER: Testing models of early Earth crust formation and tectonics

Awardee: Pennsylvania State Univ University Park

Amount: \$671,727.00

Abstract: plate tectonics is the fundamental process governing earth's dynamics, including natural hazards such as earthquakes and volcanoes. plate tectonics is a result of convection in earth's mantle. however, why mantle convection results in plate tectonics on earth, but not the other rocky planets in the solar system that also have convecting mantles, is not well understood. likewise, it is also not well known when plate tectonics started on earth. the goal of this proposal is to use numerical models of mantle convection and the formation of earth's early crust to constrain when plate tectonics might have started. observations of the chemical composition of rocks formed 3-4 gyrs ago provide key constraints on the tectonic processes operating at this time. the investigator's models will test both plate-tectonic and non-plate-tectonic scenarios for the generation of early crust against these observations, and thus assess what tectonic processes are compatible with the ancient geologic record. the results of this work will have broad significance across the geosciences. constraining the tectonic processes that operated on the early earth sheds light on how plate tectonics developed, and potentially why it is absent on other solar system planets. this work also further helps constrain on how earth's continents formed, with implications for the climate state of the early earth and possible environments for life. the proposal also makes significant contributions

to science education. it supports a graduate student who will carry out much of the proposed work, therefore furthering their research career. the project also contributes to undergraduate education through the development of a remotely taught summer short course on data analysis and visualization. this short course will be targeted at geoscience students from minority serving institutions, with the goal of helping promote **\*\*diversity\*\*** in the geosciences. the project also includes undergraduate research internships for students to be selected from the short course participants. these research internships will give students from underrepresented groups firsthand research experience, which is critical for progressing in their careers as geoscientists.

whether the early earth was characterized by a ?mobile lid? mode of tectonics, featuring subduction and surface plate motion, or a ?stagnant lid? mode where subduction is absent, is highly debated. geochemical observations of hadean and archean felsic crust provide important constraints on the tectonic processes operating at this time. however, there is still significant ambiguity, as both subduction and non-subduction, i.e. melting at the base of a thick crustal plateau, models have been proposed to explain the formation of earth?s early felsic crust. here, geodynamical models integrating new data provided by hf isotopes recorded in zircons will test the subduction and plateau melting models, from the hadean until ~ 3.5 ga. hf isotopes in zircons from many archean cratons suggest that the mafic crustal source of earth?s earliest felsic rocks (> 3.5 ga) persisted at the surface for 100s of myrs. additional petrological evidence indicates that the earliest felsic crust still preserved today formed from shallow (<30 km) melting of mafic protocrust. these observations will be integrated into two-dimensional mantle dynamic models, to test plateau melting and subduction scenarios. the modeling work will also explore the fundamental issue of whether subduction was feasible on the early earth. global models of mantle convection including crustal buoyancy and grain size evolution will be used to assess whether crustal buoyancy prevents subduction, or drastically alters its dynamics, at early earth conditions, and whether slab melting can occur when subduction is active. the results of the work will provide vital new constraints on the tectonic processes that operated on the early earth, and thus shed light on when plate tectonics might have begun. this has major

implications for the evolution of the earth as a whole, including the dynamo, crust, and even the atmosphere and oceans. the proposal also involves a significant educational component, including training of a graduate student, and a numerical modeling summer short course and reu program, geared towards students from underrepresented groups in the geosciences. a lack of programming and quantitative skills, as well as research opportunities, can be a barrier for diverse students advancing in the geosciences; the educational program developed here will seek to help address this problem. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: SBP: CAREER: Multiple Identities & Intergroup Interactions: A Dual Pathway Model

Awardee: Duke University

Amount: \$668,325.00

Abstract: this award is funded in whole or in part under the american rescue plan act of 2021 (public law 117-2). people define themselves in terms of social categories that lead to seeing similarities and differences with others. these social identities can involve being part of specific groups (for example, female) and having specific social roles (for example, mother). thinking about one's multiple identities simultaneously (for example, female, mother, scientist) has been shown to lead to increased creativity and flexible thinking. the current project examines: 1) the interpersonal benefits that may occur when individuals each consider their own multiple identities as they interact with others, and 2) the mindset and conditions that promote these interpersonal benefits. as the u.s. population becomes increasingly diverse, multiracial, and multi-ethnic, it becomes increasingly important to understand and maximize the benefits of perceiving oneself in terms of having multiple identities. the project consists of a series of studies to examine pathways that produce interaction benefits. a primary pathway involves having experiences that lead to considering one's multiple identities rather than only a single identity. another pathway involves having increased contact with

others whose identities differ from one's own, which should encourage a multiple identity mindset. these studies examine people from different groups, different ages, in different contexts, and they utilize experimental, survey, and longitudinal methods. the predictions concern whether multiple identities can: coexist simultaneously across the lifespan, be invoked or changed, vary across contexts, and also yield benefits even when some of the identities evoke negative beliefs or stereotypes. this project also provides a variety of training opportunities for the next generation of scholars, including underrepresented students. outcomes additionally include developing programming for local science museums and implementing university-level assessments that can inform campus **diversity** efforts. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: DNA Uptake By Naturally Competent Archaea

Awardee: University of Minnesota-Twin Cities

Amount: \$666,225.00

Abstract: microorganisms can acquire genetic material directly from their environment through a process called transformation. these organisms belong to two broad groups, the bacteria and the archaea. transformation is well studied in bacteria, but little is known about how this works in archaea, despite the fact that archaea represent at least a third of the bio**diversity** on earth and catalyze essential reactions in both global biogeochemical cycles in large-scale industrial and municipal bioreactors. to address this deficiency, this proposal will be the first characterization of transformation in a member of the archaea. through this work, the necessary genes and proteins needed to carry out this process will be identified. these results may further efforts to study organisms from the archaea through genetic techniques. this research has the potential to impact directly and positively research in any process that archaea catalyze. additionally, transformation is

important in natural populations, and the results generated here will help develop a broader understanding of gene flow in the environment. finally, the techniques developed as part of this research will directly contribute to the education of the next generation of scientists through graduate student training and enhancing hands-on experimentation in undergraduate and graduate classrooms. this project will characterize the process of natural transformation - the direct uptake and genomic incorporation of dna from the environment by competent organisms - in the archaeal domain. this will be accomplished by identifying and characterizing components of the archaeal dna uptake machinery involved in three distinct steps of transformation: extracellular binding of dna, transport across the cell membrane, and maintenance of dna in the cell cytoplasm. identifying the genes and proteins involved in these steps will facilitate in silico predictions of an organism's ability to take up environmental dna. this project will leverage transposon mutagenesis, in vitro biochemical analysis, and phenotypic assays to characterize transformation in *methanococcus maripaludis*, a model organism for the study of members of the archaeal domain. to further facilitate the characterization of archaeal transformation machinery, the work in this proposal will develop and utilize a system for live cell fluorescent imaging of anaerobic archaea to analyze protein localization and protein-protein interactions in competent archaea. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Microbiota Role in Intestinal Regeneration

Awardee: University of Puerto Rico-Rio Piedras

Amount: \$661,175.00

Abstract: little is known about why some animals can regenerate certain tissues or organs, while other species cannot. this research explores regeneration in a novel organism, the sea cucumber *holothuria glaberrima*. these animals have an incredible ability to regenerate lost structures and this

study will focus on the regeneration of the intestine. in recent years, the microbial environment associated with organisms, or microbiota, has been shown to play important roles in the development and proper function of an organism. this project aims to determine the possible role of the microbiota on the process of intestinal regeneration. for this study, the bacteria and other microorganisms that are associated with the regenerating intestine will be characterized to determine if and which species might be modulating intestinal regeneration. moreover, the project provides "hands-on" research training to undergraduate students as a way of guiding them toward scientific research careers and help increase the **\*\*diversity\*\*** of the scientific community. the microbiota within the digestive tract has been shown to modulate energy metabolism and immunity in both vertebrate and invertebrate species. however, little is known of their role in organogenesis and in particular in the regeneration of new organs following loss or injury. this proposal aims to extend our knowledge of the microbiota role in developmental and regenerative processes. the proposal brings together two research scientists with different areas of expertise that will join forces to focus on the characterization of holothurian intestinal microbiota and its function in the regeneration of the holothurian digestive tract. to determine the possible effects of the microbiota, state of the art technology including rna-seq and 16rrna sequencing together with more traditional microbiota analyses will be utilized. the proposed project will: (1) characterize the intestinal microbiota of two different species of holothurians, that inhabit different environments and use different feeding methods and determine the spatial and temporal changes in the microbiota during intestinal regeneration. (2) determine the role of the microbiota by modifying the microbiota using antibiotics and antifungal agents. (3) identify the host genes that are under the control of the microbiota in normal and regenerating animals by performing transcriptomic analyses of normal and regenerating animals treated with specific antibiotic agents. the outcome of the proposal will be a clear description of how the microbiota modulates intestinal regeneration, a characterization of species that play a major role in the process and the target genes involved in the process. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation

using the foundation's intellectual merit and broader impacts review criteria.

Title: IntBIO: Disentangling the genetic, biomechanical, and deep-time factors underlying mammalian skeletal diversity

Awardee: University of California-Berkeley

Amount: \$656,957.00

Abstract: understanding the relative contributions of genetic and environmental factors involved in the evolution of life (commonly framed as "nature versus nurture") is paramount to determining how bio\*\*diversity\*\* is maintained at different scales in space and time. this project examines the role of nature versus nurture in shaping skeletons and their characteristics, such as evolutionary innovations in locomotion and eating. this multi-faceted project incorporates student research teams assembled from a broad spectrum of educational backgrounds and aims to provide opportunities for students with financial need, those from community colleges, and those from underrepresented backgrounds. a mentoring-research cooperative network composed of faculty, educational program directors, and postdoctoral, doctoral, and undergraduate researchers will provide training at all participant levels. research findings will be shared broadly through an educator short course and accessible online educational materials. among the greatest challenges and opportunities for biology in the 21st century is the integration of knowledge from dispersed scientific disciplines into a generalized framework. this project focuses on the intersection of genetic heritability, biomechanics, and deep-time evolutionary patterns to disentangle the relative contributions of each factor in allowing carnivorans (dogs, cats, bears, and relatives) to become the most widespread and diverse mammalian predators in post-dinosaur earth. to gain insights into the genetic underpinnings of skeletal \*\*diversity\*\* and variation, the team will use a mouse model to construct a heritability map of phenotypic variation and covariation. this model then will be applied to carnivoran species to test hypotheses that explain skeletal variation in this group. deep-time patterns over the past 55 million

years will then be analyzed in conjunction with long-term patterns of environmental changes such as thermal maxima and ice ages. the expected outcome is an integrated framework to explain the generation and evolution of skeletal variability in a group of diverse and adaptable animals. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Amount: \$656,957.00

Abstract: understanding the relative contributions of genetic and environmental factors involved in the evolution of life (commonly framed as ?nature versus nurture?) is paramount to determining how bio\*\*diversity\*\* is maintained at different scales in space and time. this project examines the role of nature versus nurture in shaping skeletons and their characteristics, such as evolutionary innovations in locomotion and eating. this multi-faceted project incorporates student research teams assembled from a broad spectrum of educational backgrounds and aims to provide opportunities for students with financial need, those from community colleges, and those from underrepresented backgrounds. a mentoring-research cooperative network composed of faculty, educational program directors, and postdoctoral, doctoral, and undergraduate researchers will provide training at all participant levels. research findings will be shared broadly through an educator short course and accessible online educational materials. among the greatest challenges and opportunities for biology in the 21st century is the integration of knowledge from dispersed scientific disciplines into a generalized framework. this project focuses on the intersection of genetic heritability, biomechanics, and deep-time evolutionary patterns to disentangle the relative contributions of each factor in allowing carnivorans (dogs, cats, bears, and relatives) to become the most widespread and diverse

mammalian predators in post-dinosaur earth. to gain insights into the genetic underpinnings of skeletal **\*\*diversity\*\*** and variation, the team will use a mouse model to construct a heritability map of phenotypic variation and covariation. this model then will be applied to carnivoran species to test hypotheses that explain skeletal variation in this group. deep-time patterns over the past 55 million years will then be analyzed in conjunction with long-term patterns of environmental changes such as thermal maxima and ice ages. the expected outcome is an integrated framework to explain the generation and evolution of skeletal variability in a group of diverse and adaptable animals. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: CAREER: Catalytic Activation of Alkenyl C-H Bonds

Awardee: The Scripps Research Institute

Amount: \$656,000.00

Abstract: with support from the chemical catalysis (cat) program in the division of chemistry, keary engle of the scripps research institute is developing new catalytic processes to upgrade chemical feedstocks containing alkenes (molecules that contain a carbon-carbon double bond ( $C=C$ )) to more complex value-added molecules for materials, agrochemical, and chemical biology/medicinal chemistry applications. palladium-based catalysts that are capable of selecting specific alkene carbon-hydrogen bonds ( $C-H$ ) bonds and activating these for  $C-X$  bond formation are being studied. insight into how these catalysts work is also being investigated to differentiate key features from related catalytic transformations. in parallel, dr. engle and his research team are leading synergistic activities to expand access to cutting-edge educational experiences for underserved students and to enhance the **\*\*diversity\*\*** and global competitiveness of the science, technology, engineering, and mathematics (stem) workforce. these efforts include developing open-access graduate courses and learning resources, expanding programming offered through a stem pipeline consortium that serves

diverse undergraduate students from local two- and four-year colleges in san diego, and involving undergraduate and high school interns from historically underserved groups in research activities. overall, this research program is helping to improve the efficiency and sustainability of industrially relevant chemical processes, while bolstering the future stem workforce of the united states.

catalytic reactions that convert carbon-hydrogen bonds into new carbon-carbon and carbon-heteroatom bonds enable the rapid synthesis of valuable target compounds with reduced waste generation compared to traditional approaches. keary engle and his team at the scripps research institute are developing palladium-catalyzed C(alkenyl)-H activation reactions and studying the factors that promote C(alkenyl)-H activation versus other reaction manifolds that typically emerge from alkene-palladium(II) species. these catalytic transformations are simultaneously being optimized to convert readily accessible mono- and disubstituted alkene starting materials into more highly-substituted alkene products that are otherwise difficult to prepare with defined regio- and stereochemistry. activities further include mechanistic studies, directing group investigations, and the use of alkene isomerization strategies to understand the catalytic process and to broaden the reactivity to include a significant variety of alkene substrates for these catalytic systems. this multidisciplinary project will integrate insights from mechanistic organometallic chemistry, and organic synthesis, providing a holistic and innovative training experience for a diverse group of high school students, undergraduates, ph.d. students, and postdoctoral fellows. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: BPC-AE: STARS: Catalyzing Action-Oriented Academic Communities for Broadening Participation in Computing

Awardee: North Carolina State University

Amount: \$652,289.00

Abstract: it is critical to address the longstanding issue of underrepresentation of women, black, and hispanic students in computing degree programs to provide an equitable foundation for all to participate in our society and the global economy as controllers and creators of technology, and to advance the preparation of a diverse, innovative, and competitive tech workforce. building on the prior success of the stars computing corps alliance for broadening participation in computing, the goal of the stars catalyst project is to: 1) increase the number of women, black, and hispanic students that persist in computing degree programs, and 2) advance the careers of students and faculty from groups that have been historically underrepresented in computing. through research and evaluation around stars catalyst activities, this project will advance knowledge about practices designed to increase persistence and support career advancement in computing for college computing students and faculty, particularly for those from underrepresented and intersectional groups in computing. the stars catalyst alliance is a collaborative effort across temple university, north carolina state, kent state, florida state university, morgan state, and university of north carolina charlotte. the stars computing corps alliance for broadening participation in computing (bpc) engages computing faculty and students at colleges, universities, and community colleges in a

community of practice with a shared commitment to take action to advance **diversity**, equity, and inclusion in computing. stars computing corps conferences, communities, and networks create significant institutional and human resources that can expand bpc research to a larger audience of researchers, educators, administrators, cs departments, and k-20 students, and can dramatically increase the number of people taking action in bpc efforts. prior results show that the stars computing corps alliance increases intentions to persist in computing among stars students and faculty, with enhanced outcomes for black students and faculty. this project will significantly extend the stars alliance to expand upon those impacts, by 1) including new partners that expand the reach of stars and that emphasize participation of black and hispanic students and faculty, particularly from emerging hispanic serving institutions and community colleges, 2) creating new program elements that test new and propagate evidence-based bpc practices within computing departments, and 3) leveraging partnerships to support identity-focused affinity groups, and 4) developing stars alumni groups employed in industry positions to promote transition to and retention within the tech workforce. extensions to the stars leadership corps program, stars launch program, and the stars celebration conference will serve to develop and propagate evidence-based approaches aimed at improving the teaching and learning of computing for black and hispanic students and build evidence of their effectiveness, and the respect research conference will continue to advance peer-reviewed bpc scholarship. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Creating a Novel Museum-Based Resource for Neuroscience: Mass whole-slide imaging of the R. Glenn Northcutt Collection of Comparative Vertebrate Neuroanatomy and Embryology

Awardee: Harvard University

Amount: \$651,747.00

Abstract: this project will enable online access to a unique, irreplaceable resource for comparative studies of the evolution and development of the vertebrate brain. the r. glenn northcutt collection of comparative vertebrate neuroanatomy and embryology, housed in harvard's museum of comparative zoology (mcz), is the world's largest and most taxonomically diverse collection of histological preparations of developing and adult vertebrate brains mounted on glass microscope slides. it is of particular interest and relevance to the current generation of neuroscientists who use molecular and genetic approaches to elucidate mechanisms underlying evolutionary innovations, but the slides are fragile and access to them is difficult and time consuming. by utilizing a whole-slide-imaging workflow developed through a novel collaboration with harvard's center for brain science, the project will allow professional scientists, educators and students to easily and routinely access the slides' content via high-resolution digital images. such access will facilitate use of the slides in research and education and complement novel technologies for studying brain structure, development and function. it will facilitate collaborations between the neuroscience and bio\*\*diversity\*\* communities and, together with other projects that seek mass digitization and sharing of biological collections, it will enhance the ability of natural history institutions to more fully serve both science and society beyond their traditional constituencies. indeed, the project's imaging workflow and associated training components offer an exemplar method for rapid and cost-effective digitization that can be used by other institutions, whose slide holdings number in the millions, most of which remain dark data. the project will use a high-throughput, semi-automated slide scanner to make high-resolution digital images of the approximately 33,000 glass microscope slides in the northcutt collection. when completed, the project will provide online access to approximately 500,000 serial sections and whole-mount preparations of adult brains and embryos of more than

240 genera and 270 species of living vertebrates. a cost-effective whole-slide imaging workflow will be utilized to process as many as 360 slides/week while yielding excellent image resolution (0.2 and 0.4  $\mu$ m/pixel at 40x and 20x magnification, respectively). a digital image of each slide will be served to potential users via two online portals: mczbase, the museum of comparative zoology's permanent specimen database; and morphosource, an nsf-supported online repository for specimen digital imagery. both portals will be configured with girder and slideatlas, two open-source software tools for whole-slide image viewing, downloading and analysis. in addition, for as many as 20 species widely used to teach comparative vertebrate anatomy, digital images of a subset of histological sections labelled to point out principal brain regions will be uploaded to brainmaps, an online resource for vertebrate neuroanatomy. finally, the project will produce several resources for training both students and professionals in methods for mass digitization and computer-assisted visualization of slide collections regardless of subject matter. these resources include four "how-to" videos, two online tutorials, undergraduate and graduate student internships and a graduate-level course in museum studies. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: IUCRC Phase II: Iowa State University: Center for Bioplastics and Biocomposites [CB2]

Awardee: Iowa State University

Amount: \$651,714.00

Abstract: the center for bioplastics and biocomposites (cb2) at iowa state university (isu), university of georgia (uga), washington state university (wsu), and north dakota state university (ndsu) seeks to develop and build on an industry/university cooperative research center (i/ucrc) that focuses on bioplastics and biocomposites. the mission of cb2 is to develop fundamental knowledge related to bioplastics and biocomposites, to disseminate research-based findings to industry to promote

sustainability, and to educate future scientists and engineers. as such, there is an expressed industrial interest in leveraging research efforts to accelerate systematic development of standardized material and processing data for these novel plastics and composites. the center focusses on the development of jobs in the area of sustainable manufacturing and the conversion of agricultural and woody crops to bio-based materials that contribute to job creation in the united states. the center also strives to support education and **\*\*diversity\*\*** through engagement of undergraduate and graduate students in research on sustainable materials. the goal of cb2 is to improve the basic knowledge of synthesis, processing, properties, and compounding of bioplastic and biocomposite materials, to develop reliable materials characteristics data for industrial partners, and to support large-scale industrial implementation of renewable materials. the vision of the center is to develop knowledge that will facilitate the production of an array of high-value products, including plastics, coatings, adhesives, and composites, from renewable feedstocks. the materials are compatible with current industrial manufacturing systems and promote rural development as well as national growth. the goals of the phase ii are fourfold: 1) expand the knowledge and develop the science for recycling and end of life treatment of sustainable materials, in particular as they are mixed with petrochemical plastics; 2) expand membership by engaging new companies that have expressed a need for recycling and end of life treatment; 3) develop fundamental knowledge on sustainable materials; 4) prepare students to join the workforce equipped with the knowledge and skills required by industry. the team of researchers includes experts in the fields of polymer processing, polymer chemistry, materials science, and crop utilization. wsu's research focuses on utilizing industry-relevant technology platforms to develop bio-based composites, coatings and adhesives, and polymers for various industry applications, as well as to recycle bio-based composite materials. isu's research focuses on agricultural biomass valorization, monomer and polymer development, adhesives and coatings, chemical recycling and upcycling, and packaging and construction materials markets. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts

review criteria.

Title: CAREER: Simulating Mesoscale Quantum Dynamics and Non-linear Microscopy

Awardee: Southern Methodist University

Amount: \$650,000.00

Abstract: this award is funded in whole or in part under the american rescue plan act of 2021 (public law 117-2). with support from the chemical theory, models and computational methods program in the division of chemistry, doran bennett of southern methodist university is working to uncover the quantum mechanical processes by which molecular materials conduct energy. next generation technology development stems from advances in our ability to control, manipulate, and redirect energy. dr bennett's group will extend computer simulations of quantum process from the traditional molecular-scale to the nanometer-to-micron scale, (i.e. the "mesoscale") that is relevant to molecular materials. these rigorous computational models are expected to establish how specific materials absorb and deploy energy from light, providing essential information to those looking to

engineer novel materials. this research will combine chemistry, computation, and advanced mathematics, stem fields with severe levels of gender and race disparities. in conjunction with his research, dr. bennett will launch an intensive, wrap-around summer research program to reach greater numbers of science majors from underserved groups in an effort to achieve greater excellence through **\*\*diversity\*\***. doran bennett?s research under this award will address the pressing need for new computational tools to support an emerging scientific frontier studying mesoscale (10 nm ? 1 ?m) excited-state dynamics in molecular materials. rapidly developing synthetic and spectroscopic toolboxes are expected to enable structural control and the establishment of spatially-resolved probes of mesoscale processes. dr. bennett and his group will leverage the locality of electronic excited-states to simulate the photophysics of molecular materials within a formally exact (spin-boson) equation-of-motion called the adaptive hierarchy of pure states (adhops). dr. bennett will extend adhops to simulate excited state dynamics in the presence of complex vibrational environments of realistic molecular materials (e.g. involving many frequencies of vibration and timescales of relaxation). he and his team will also endeavor to develop the corresponding computational methods for simulating spatially resolved non-linear spectroscopy. these efforts are expected provide the community with new theoretical tools for interpreting spectroscopic measurements and predicting excited state dynamics in synthetic molecular materials. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: CRCNS Research Proposal: Computations for spatial-chromatic interactions and their physiological implementation in primary visual cortex

Awardee: University of Maryland, College Park

Amount: \$649,791.00

Abstract: color and form are often treated as separable features of an image. one can recognize

shapes in achromatic photographs and conceptualize the color of an object abstracted from shape. yet color-specific processing is embedded throughout the visual pathway from the first stage of the visual pathway, where three different types of light sensors (?cones?) with sensitivity to different parts of the visual spectrum initially convert light into electrical impulses. the color of a given point can in principle be determined by comparing the activation of the three different cone types, but the separate color channels are maintained until the primary visual cortex (v1), where they are finally combined in neurons that concurrently have sensitivity to different spatial patterns. indeed, while it was initially thought that color and form were processed through separate pathways within v1, recent experiments have highlighted that a surprising fraction of v1 neurons mix them together in a **\*\*diversity\*\*** of ways. exactly how the mixing occurs, and for what purpose, are critical open questions in understanding human vision, and have been difficult to answer because such mixing is too complicated to characterize using traditional approaches. this project combines large-scale recording of v1 neural activity during tailored ?spatio-chromatic? visual stimulation with new computational approaches that offer an unprecedented high-resolution description of color processing within v1 while allowing determination of the underlying function of spatio-chromatic mixing in supporting natural color vision. the project also provides opportunity for cross-disciplinary training in neurophysiological and machine-learning based statistical modeling of undergraduate and graduate students. this project is a tight combination of visual neurophysiology, data-driven computational modeling, and simulation. the investigators perform large-scale multi-electrode recordings across cortical lamina to determine the transformations of spatio-chromatic representations from cortical inputs (where color channels are separate) to cortical outputs (where they are mixed). these recordings are interpreted using nonlinear data-driven models that can provide high-resolution spatio-chromatic maps of the stimuli driving each v1 neuron, and distinguish the underlying computations being performed at each stage. such characterizations are pushed to achieve cone-resolution by leveraging novel model-based eye-tracking that can account for small eye movements with an order-of-magnitude finer sensitivity than standard approaches. the first aim

determines the set of principles governing how spatial and chromatic information is combined in v1, which sets the foundation for processing throughout the visual pathway. the second aim determines whether these rules are the same in the area of cortex processing the center-of-gaze (fovea), which is responsible for high-acuity color vision. finally, the last aim establishes a population decoding framework for linking spatio-chromatic sensitivity of individual v1 cells to the larger systems-wide goals of the visual cortex in processing natural color vision. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: CAREER: Alterations in Marine Bivalve Shell Formation by Environmental Stress

Awardee: Texas A&M University Corpus Christi

Amount: \$648,557.00

Abstract: shellfishes use shells to protect themselves from predators and obtain nutrients from the water. shells are tough since the compounds in them are harder than rocks. however, the toughness of shells can be easily affected by environmental conditions during the shell formation. shells can become fragile when the shell formation occurs in adverse conditions, such as high carbon dioxide (co2) level or low salinity in water. with the effects on shells, the production of some shellfish species with high market values, such as the oysters, will be possibly declined in the coastal areas. the research goal of this career proposal is to understand how the co2 and salinity of water modify the eastern oyster shell formation from a genetic level so that a method to help the oysters overcome the environmental effects during the shell formation. the result of this study will be applied to oyster aquaculture in the gulf of mexico. the project will also help with restoration of shellfish habitats on the coast. in addition, the project will involve the training of students from historically underrepresented groups in science at texas a&m university ? corpus christi via the educational goals of the project. the project will also provides research opportunities to community college

students, as well as research opportunities for middle/high school science teachers in the biological sciences. It is well known that the shell development during the early life stages of bivalves is vulnerable to environmental stressors, but there is little understanding of the genetic responses of bivalves to environmental changes during shell development. The research goal of this career project is to determine the molecular mechanisms by which bivalve shell formation is altered under ocean acidification (OA) and salinity fluctuation. The proposed approach is to 1) characterize changes in oyster shells under the stress of OA and salinity fluctuation by measuring the shell morphological changes, analyzing changes in shell composition, and identifying changes in matrix protein production of the shells; 2) identify the signaling pathway for shell formation response to OA and salinity stress by conducting transcriptomic analysis and calcium imaging with the primary cell cultures from the mantle tissue of the eastern oyster; and 3) enhance the tolerance of the eastern oyster shell formation to the environmental impacts by creating mutagenesis and transgenic strains. The education goals of the proposed project are to increase **diversity** in higher education and biological research, focusing particularly on encouraging hispanic/latino students to pursue advanced degrees in STEM fields. The approach will be to 1) create an innovative class for undergraduate and graduate students that involves multiple off-campus experts and facilities in teaching and student-learning outcome assessment; 2) providing research opportunities to undergraduate students and community college students; and 3) organizing a summer biological science section for middle/high school students and a training section for elementary/middle school teacher education. This award reflects NSF's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Evolution of the gene regulatory network for pharyngeal segmentation

Awardee: University of Colorado at Boulder

Amount: \$645,487.00

Abstract: the bones and cartilages of the jaws, face, neck, and inner ear develop from embryonic structures called pharyngeal arches. defects in pharyngeal arch development underlie many human birth defects. the pharyngeal arches of non-human vertebrates also form most of the head skeleton, including the gills of aquatic vertebrates. though the pharyngeal arches form similarly in all vertebrates, they ultimately give rise very different head skeletons in different vertebrate groups. how such variation is achieved using the same basic set of genes and developmental processes is unclear. the project seeks to elucidate the aspects of pharyngeal arch development shared by all vertebrates, and those that differ between major groups. this information will serve two purposes. first, it will shed light on the genetic and developmental changes that led to the evolution of new vertebrate groups. second, it will help identify the causes of genetic and environmentally-induced disruptions human craniofacial development. this project will also support the creation and staffing of

a large, interactive zoo exhibit entitled "hidden links: discovering your inner invertebrate", that will be seen by over 300,000 visitors annually, including 57,000 grade school students. the exhibit will expose visitors to key biological concepts such as evolution, phylogenetics, genetics, segmentation, and development. the work will also support the training of three ph.d. students, several undergraduates, and provide research projects for 1-2 high school students per year. robust, paired pharyngeal arches (pas) are a defining feature of vertebrates. pas form most of the breathing and feeding structures of the vertebrate "new head", and variation in pa number and derivatives is a major contributor to vertebrate morphological \*\*diversity\*\*. though pas play a key role in shaping the vertebrate head, the genetic mechanisms driving pa development are poorly understood. even less is known about how they have been altered during evolution to yield different oropharyngeal phenotypes. the pas form in an anterior-to-posterior sequence when bilateral endodermal outpocketings called pharyngeal pouches (pps) contact overlying ectoderm. studies in zebrafish, medaka, and mouse have identified a small, conserved set of genes that drives pp development in model vertebrates. however, how these genes interact differs between teleosts and mouse. when during evolution these gene regulatory differences arose, and if they contribute to differences in oropharyngeal morphology, is unknown. to better understand the genetic bases of vertebrate oropharyngeal \*\*diversity\*\*, this work will reconstruct the ancestral gene regulatory network for pp/pa development (the pp grn). this information will then be used to deduce how and why the pp grn has been altered in modern lineages. to do this, the pp grn of the sea lamprey, *petromyzon marinus*, and the frog, *xenopus laevis* will be interrogated using crispr/cas9 mutagenesis and pharmacological perturbations. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: REU Site: Undergraduate Research Pathways That Broaden and Strengthen the Geosciences

Awardee: Macalester College

Amount: \$642,244.00

Abstract: the keck geology consortium reu will offer undergraduate research experiences for 14 undergraduate students per year to help students: (1) improve their understanding of the earth through authentic research; (2) develop disciplinary and personal skills needed by professional earth scientists; (3) develop their confidence and identity as scientists through greater understanding of the intellectual and practical work of science; and (4) refine their career plans and prepare them for graduate study using intentionally designed research experiences and mentoring. gateway projects, designed for rising sophomores, will engage students in a mix of field and laboratory work to investigate societally relevant questions, expose them to the breadth of the discipline, and to career opportunities in the earth sciences. students in the advanced research program (rising juniors) will participate in a four-week summer project involving a mix of field and laboratory investigations, followed by an academic year-long project at their home campuses, that focuses on important problems in the discipline. both programs include analytical, professional development components, and conference presentations designed to help students learn cutting-edge approaches, as well as to develop their professional knowledge and skills. mentor workshops, curricular materials, and technology are used to support the work of student participants and project mentors. the principal goal of keck geology consortium programs is to broaden the **\*\*diversity\*\*** of the geoscience workforce and to prepare students for careers in the geosciences. undergraduate participants, especially those from underrepresented minorities, will be recruited from both consortium and non-consortium institutions. the gateway program is designed to further existing efforts at the consortium institutions to broaden the participation of underrepresented groups within the geosciences and stem. with an emphasis on year-long research experiences, structured research curricula, and mentor training, the consortium programs provide a distinctive model for undergraduate research. this project also endeavors to advance the evaluation of undergraduate research experiences with further development of a research knowledge and skill survey and to

facilitate community-wide engagement with ?science identity? formation with a goal of simultaneously strengthening reu?s and geoscience programs. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Digitization TCN: Collaborative Research: Bringing Asia to digital life: mobilizing underrepresented Asian herbarium collections in the US to propel biodiversity discovery

Awardee: Missouri Botanical Garden

Amount: \$642,096.00

Abstract: asia is the largest continent on earth, and includes the world?s tallest mountains, lowest landscapes, and habitats ranging from arctic tundra to tropical rainforests and mangroves to deserts. the plants of this region are incredibly diverse in their identities and functions. more than one-third of the world?s 350,000 plant species grow in asia and include tiny alpine cushion plants, medicinal herbs, ancient crops, and some of the planet?s tallest rainforest trees. but documentation of this **\*\*diversity\*\*** remains inaccessible and research about it is difficult because most herbarium specimens of asian plants have not been digitized. the all asia thematic collections network (tcn) will mobilize online 15 million specimens of asian plants currently housed in the us and around the world. the project will especially focus on digitizing specimens from the unique and critically endangered bio**\*\*diversity\*\*** hotspots of southeast asia and the himalaya-hengduan region. these mobilized digital data will accelerate research to conserve endangered plant species and understand the interacting effects of evolution and global environmental change on plant species **\*\*diversity\*\***. the project will apply state-of-the-art informatics tools and high-throughput digitization methods to efficiently and affordably digitize an unprecedented number of herbarium collections. this effort will connect and build long-lasting relationships among 25 large and small consortium institutions in the u.s., europe, and asia. the focal areas from which specimens will be digitized

encompass five bio\*\*diversity\*\* hotspots that include ~20% of the world's vascular plant flora and historically spanned 3 million km<sup>2</sup> of primary vegetation that now covers less than 300,000 km<sup>2</sup>. fundamental bio\*\*diversity\*\* data for these bio\*\*diversity\*\* hotspots are lacking, along with the necessary baselines required to characterize species' identity, range, and responses to ongoing climatic change. the overall goals of the all asia tcn are to rapidly digitize herbarium specimens of asian plants to advance bio\*\*diversity\*\* discovery and provide critical baseline assessments essential for establishing floristic change in the anthropocene. the project will accomplish this by (1) digitizing 3 million asian vascular plant specimens from u.s. herbaria; (2) developing and applying novel informatics tools and high-throughput digitization methods to massively scale herbarium digitization; (3) aggregating and mobilizing the digitized records from the project with those by international partners in china, france, the netherlands, and russia to establish a single online all asia portal of ca. 15 million specimens; and (4) enhancing opportunities for early career learners in science, technology, engineering, and mathematics by stimulating synergies between bio\*\*diversity\*\* and computer scientists who will use design thinking principles to create real-world informatics solutions to bio\*\*diversity\*\* challenges. to stimulate curiosity in plant \*\*diversity\*\* and botanical exploration among the general public, the consortium members will host several asia-themed notes from nature virtual expeditions to facilitate additional specimen digitization by citizen-scientists. digitized specimen data mobilized through this project will be shared and made available through idigbio.org. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: CAREER: Supramolecular Chemistry at the Interface of Lipid Bilayers and Water

Awardee: Tulane University

Amount: \$641,520.00

Abstract: this award is funded in part under the american rescue plan act of 2021 (public law 117-2).

with support from the macromolecular, supramolecular and nanochemistry program in the division of chemistry, nathalie busschaert of tulane university will study the fundamental supramolecular chemistry behind small molecules that interact with lipids in biological membranes. lipids are an important class of biological compounds and play a role in a variety of physiological functions, such as energy storage, providing a hydrophobic barrier, and signal transduction. there is therefore a need for small molecules that can interact with certain types of biological lipids. the biggest challenge, however, is that lipids mostly reside in membranes as 'lipid bilayers' that possess unusual physical properties complicating the development of lipid-binding molecules. dr. busschaert aims to design novel small molecules that can selectively bind to one type of lipid over other types of lipids and study the effect of various physical membrane properties on this binding event using model liposome-based systems. the project is anticipated to help establish general guidelines for the design of molecules that can selectively bind to specific lipids within lipid bilayers, which can have a broader impact on the field of supramolecular chemistry by exploring lipids as an unusual target, help elucidate lipid biochemistry and biophysics, advance human health and provide fundamental knowledge for any application involving membranes. this work is expected to have a further broader impact on the participation of women in stem fields, as dr. busschaert will oversee a number of supramolecular chemistry inspired activities to increase the participation of women and minorities in stem at every level of education. the central hypothesis of the project is that lipid head-groups are comparable to traditional supramolecular targets such as phosphate anions and ammonium cations, but that the unusual physical properties of lipid bilayers need to be considered when designing lipid-binding molecules. so far, there have only been a few reports of small molecules binding selectively to certain types of lipid head-groups. however, in most cases the binding of the host molecules with the lipid of interest was determined in organic solution or in one type of liposome. such investigations ignore the lipid **diversity** in biological membranes and do not take into account the effects of the unique physical properties of lipid bilayers. the binding of lipid

head-groups takes place at the membrane-water interface, which makes it an unusual type of supramolecular interaction. the interface region is partially hydrated and is therefore presents a different situation from that observed with supramolecular interactions in water and or in organic solution. furthermore, lipid bilayers display a fluid, liquid crystalline state that displays neither solution kinetics nor solid state dynamics. the central hypothesis will be tested by synthesizing a variety of compounds designed to bind to specific lipid head-groups, and then characterizing the binding of these compounds with model liposome-based systems using a variety of techniques, including nuclear magnetic resonance (nmr), uv-vis spectroscopy, surface plasmon resonance and isothermal titration calorimetry. these activities are designed to help identify the effect of hydrophobicity, physical membrane properties (e.g., lipid shape, acyl chain length, membrane curvature), and multivalency on binding to lipid bilayers. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: CAREER: Diversity in Learning Contexts and the Emergence of Abstract Reasoning

Awardee: University of California-San Diego

Amount: \$636,044.00

Abstract: relational reasoning is the ability to go beyond direct, perceptual experience to engage in abstract thought. it a defining feature of human cognition and critical for scientific thinking. however, young learners often struggle to prioritize abstract concepts, like same and different, over salient, but often less informative properties, like color or shape. the investigator will explore how distinct learning environments may shape children?s tendency to engage in relational reasoning to better understand what circumstances facilitate (or suppress) this ability. this project will engage in cross-cultural work to examine if and how naturally-occurring differences in environmental input influence the early expression of abstract thought. additional research will assess whether specific learning environments may be manipulated to facilitate skills for abstraction in children. this work challenges existing theories that posit the gradual, linear emergence of relational reasoning, and will generate an empirical foundation for thinking broadly about cognitive **\*\*diversity\*\***. further, establishing competence in abstract reasoning provides an incentive for designing learning environments to support recognition of these concepts from an early age. the proposed work tests the claim that although relational reasoning emerges early, children tend to neglect abstract similarity due to a learned bias to attend to object properties. this account predicts that variation in children?s environmental input should lead to distinct cognitive biases and corresponding

differences in the expression of abstract thought. the investigator will apply a three-pronged strategy to assess this account. aim 1 will evaluate the robustness of early competence in relational reasoning in 18-30-month-olds in two different cultural contexts to assess whether their previously reported success results from genuine conceptual understanding. aim 2 will characterize differences in object- and relational-focus in 3-year-olds across additional cultures and document effects on reasoning. this will evaluate claims that differences in lexical bias and context-sensitivity influence the emergence of abstract thought. aim 3 will assess the causal role of contextual factors on reasoning in children by manipulating features of the learning environment. together, these aims test the claim that early challenges associated with relational reasoning do not result from a lack of competence, but rather a difference in tendency that stems from children's failure to recognize when to apply their knowledge. this approach promotes the investigation of diverse populations and challenges the prevailing view that children's reasoning universally develops as a bottom-up, emergent process. findings from this project will advance our understanding of how regularities in the environment may set the developing child on different learning trajectories. this project is co-funded by the sbe/bcs science of learning and augmented intelligence, the discovery research prek-12 (drk-12), and the ehr core research (ecr) programs. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: CAREER: Developing noble gases as tracers of metamorphic dehydration

Awardee: Pennsylvania State Univ University Park

Amount: \$635,630.00

Abstract: the habitability of earth is controlled by the distribution of volatile elements (e.g. water, carbon dioxide) between surface (atmosphere + hydrosphere) and interior reservoirs (mantle + core). metamorphism during burial and heating of oceanic plates at subduction zones regulates the

supply of water into the earth's mantle, critically affecting how the mantle flows. however, the specific pathways and fluxes by which water is transported beyond arc volcanoes are uncertain. while direct tracing of subducted water is made difficult by its small number of isotopes, the noble gases are elementally- and isotopically-rich, are fractionated by physical processes and are ideal tracers for the movement of metamorphic fluids. application of the noble gases as tracers of the deep water cycle requires development of a linkage between noble gas composition and the magnitudes of water loss during subduction. this project will result in a systematic characterisation of the distribution and composition of noble gas isotopes in ancient samples of subducted oceanic crust, establishing the framework for noble gases to be used as tracers of metamorphic fluids. the integrated research and education program proposed here will result in: 1) quantification of the key physical processes that control subduction-processing of volatiles; 2) career-enhancement for an early career scientist and a graduate student, and 3) broadened participation and enhanced **\*\*diversity\*\*** in petrological research via a series of formative research institutes targeting applicants from minority-serving institutions. earth's upper mantle contains an indelible elemental abundance pattern of heavy noble gases (ar, kr, xe) that is strikingly similar to seawater. because this is a unique composition in the solar system, the only credible explanation is that a non-disrupted, seawater-like noble gas signature survives the subduction process, generally thought to exclude more than 95% of input volatiles. given that the noble gases are between 100 and 100,000 times more soluble in fluids than crustal minerals, even minor amounts of phase separation during release and transport of metamorphic fluids will fractionate the noble gas composition of subducting rock. how, then, do noble gases escape removal and significant fractionation during subduction? and, can the noble gases be used to quantitatively trace the subduction of water? this project will address these questions through the integration of noble gas compositions, mineralogically-bound h<sub>2</sub>o contents and thermodynamic estimates of pressure and temperature from exhumed subduction-related rocks. the proposed research will systematically test the overarching hypothesis that noble gas composition is principally controlled by the extent of metamorphic dehydration during

subduction. at the core of the educational component of this career program is the development and implementation of a series of summer institutes dedicated to enhancing **\*\*diversity\*\*** in petrological research. this program will result in the petrological training of a cohort of undergraduates, many of whom will come from minority-serving institutions. petrological and geochemical datasets collected as part of the proposed research program will be used to nurture interest, and increase comprehension of undergraduate students, from a diverse array of institutions and backgrounds, in metamorphic petrology. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Applying Student Knowledge for Success in Cybersecurity and Data Science

Awardee: Brookdale Community College

Amount: \$633,935.00

Abstract: this project will contribute to the national need for well-educated scientists, mathematicians, engineers, and technicians by supporting the retention and graduation of high-achieving, low-income students with demonstrated financial need at kean university, the new jersey institute of technology, fairleigh dickinson university, brookdale community college, and union county college. in particular, it responds to areas of national need in cybersecurity and data science by increasing the number of students graduating in computer science (cs) and information technology (it). moreover, the project will build regional workforce strength and contribute to the knowledge base on the role of student competence and belonging in ensuring persistence to degree attainment. over its five-year duration, a total of 256 students will benefit, receiving scholarships to complete cs or it degrees. project components include scholarship support for students, undergraduate research and/or professional experience opportunities prior to graduation, and generation of new knowledge through research on economic realities for students and impact on career trajectories in cybersecurity and data science. students in this program will be prepared to enter the scientific workforce or graduate school as competent, highly trained individuals with a background in teamwork and research. furthermore, they will contribute to increased professional **\*\*diversity\*\*** in the fields of cs and it, and serve as role models to members of their communities.

the students recruited for this program will participate in workshops, take advantage of cohort experiences, and interact closely with faculty who will provide i) academic advising, ii) guidance for navigating higher education and postgraduate opportunities, and iii) supervision of teamwork, research, and working professional experiences. through undergraduate research opportunities and experiences from participation in faculty research programs and/or existing summer research and

internship programs, these individual and cohort experiences will provide a basis for overall intellectual growth and promote increased student confidence, retention, and timely degree completion. these academic outcomes are in turn expected to allow students to successfully navigate common attrition points including financial hardship and professional identity development for post-graduate employment and continued education. the project's academic environment includes student-faculty advising and undergraduate research activities, using the affinity research group (arg) model and peer-mentoring. the use of teamwork, collaboration and student-motivated question and answer sessions will positively support research in the field of computer science and information technology regarding educational impact and retention, particularly for minorities, female, and first-generation students. this project is funded by nsf's scholarships in science, technology, engineering, and mathematics program, which seeks to increase the number of low-income academically talented students with demonstrated financial need who earn degrees in stem fields. it also aims to improve the education of future stem workers, and to generate knowledge about academic success, retention, transfer, graduation, and academic/career pathways of low-income students. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: HDR DSC: Building Capacity in Data Science through Biodiversity, Conservation, and General Education

Awardee: Lewis and Clark College

Amount: \$633,278.00

Abstract: solving environmental challenges relies heavily on computer science and statistical skills applied to large data sets. however, these knowledge, skills, and abilities are not evenly distributed across u.s. colleges, students, or faculty. this project works to transform environmental education by

creating, implementing, and evaluating a data science training program for undergraduate students who are interested in conservation and management in urban and wild areas. faculty from both the university of arizona and lewis and clark college co-teach a foundational data science course that utilizes public data and addresses pressing environmental concerns relevant to student interests and identities. exceptional students subsequently participate in a more focused cooperative course as data science interns for conservation stakeholders. professional development workshops in data science education for instructional faculty, some of whom work in institutions serving primarily low-income students and students of color, prepare faculty to implement data science educational modules at their respective institutions. these critical resources and pathways allow broad communities to harness the data revolution. the workforce demand for data analysts and data scientists exceeds the current capacity for higher education to produce this skilled workforce. the overall goal of this project is development of scalable, portable data science education that can be readily incorporated into existing programs concentrating on stem (science, technology, engineering, and mathematics), with a focus on ecology, bio\*\*diversity\*\*, and conservation. the project achieves this goal by creating multiple curricular data science on-ramps for a broad range of students early in their undergraduate training, through general education courses and foundational major courses using inclusive and expansive pedagogy techniques more common in liberal arts education. the expected outcomes from these activities are (1) development of reusable data science modules and courses that can be deployed into existing undergraduate general education and major curricula, (2) the ability for a broad range of conservation interested students to access real-world data science training they are passionate about at an early stage of their education, and (3) training and support mechanisms for undergraduate educators who wish to add data science to their curricula. the products of this proposed multi-institutional data science corps program are designed to be generally extensible to other higher educational institutions and majors through open data and open science, providing capacity to rapidly deploy data science training. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's

intellectual merit and broader impacts review criteria.

Title: Collaborative Research: A Data-Driven Employer-Academia Partnership for Continual Computing Curricular Change

Awardee: Purdue University

Amount: \$632,615.00

Abstract: this project aims to serve the national interest by improving the supply of well-prepared computer science professionals capable of addressing the needs of american employers in the public and private sectors. this project intends to build a national partnership between employers and academia to help identify and mitigate gaps between the competencies of computing graduates and the expectations of potential employers. the project will survey computer science educators and practitioners to develop a model that defines the competencies expected by potential employers. the project team then plans to test the model at three institutions of higher education in alabama ? the university of alabama, tuscaloosa, tuskegee university, and shelton state community college. finally, the project team intends to develop tools and methods for institutions to identify and implement competency-based educational approaches for computer science across the nation. the project plans to use three interconnected strands of evidence-based activities to institute transformational change in the involved communities. first, a national strand will engage u.s. faculty in developing competency-based curricula informed by industry practitioner feedback. second, a local pilot strand intends to create transformative curricular change based on student competencies using an evidence-based change model in the three alabama institutions. sociologists and computing faculty on the team will help to understand, predict, and reduce barriers to competency-based employment of computing graduates from marginalized communities in the heart of the impoverished alabama black belt. the unique perspective relative to **\*\*diversity\*\***, equity, and inclusion needs should serve as a model for other computing departments. the third strand will

develop competency-based surveys for practitioners and academics to identify and refine specific competencies that are hoped to drive continual curricular change. outcomes, including the change process, national workshops, and experiences from the local process will help with transferability in the computing education community. in addition to informing curricula, the project will provide valuable data for educational researchers to help close the gap between employers and higher education. finally, as the competency approach to curricular design is relatively new in computing and engineering disciplines, lessons from this project will have the potential to transform curricular review and design in other stem disciplines. the nsf iuse: ehr program supports research and development projects to improve the effectiveness of stem education for all students. through the institutional and community transformation track, the program supports efforts to transform and improve stem education across institutions of higher education and disciplinary communities. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Understanding Context: Propagation and Effectiveness of the Concept Warehouse in Mechanical Engineering at Five Diverse Institutions and Beyond

Awardee: Tufts University

Amount: \$631,082.00

Abstract: an increase in the number and **\*\*diversity\*\*** of graduates in science, technology, engineering, and mathematics (stem) fields is important for the nation's competitiveness. concept-based active learning strategies have been shown to improve students' academic performance and increase the number who choose to stay in stem programs. however, scientific proof that these strategies are effective is not enough to make sure instructors use them in courses. it is also necessary to understand and find ways to get instructors to adopt proven practices. in this project new online concept-based materials for mechanical engineering courses in statics and

dynamics will be developed. the project team will study why instructors decide to use the materials, and how factors at five different types of institutions affect these decisions. the project will help to show how circumstances at different institutions affect both instructor adoption as well as student learning and motivation. it will help inform ways to support widespread use of the evidence-based instructional practice. thus, it will also help more students stay in and graduate from engineering programs. the goal of this project is to increase the adoption of concept-based active learning throughout undergraduate engineering programs. it builds upon the project team's previous success in developing the web-based concept warehouse instructional resource for chemical engineering. the resource contains hundreds of short questions to engage students in concept-oriented thinking, to assess their conceptual knowledge, and to provide extensive concept-based active learning tools. the project will expand concept warehouse to include content in mechanical engineering. participating institutions include research-intensive and hispanic-serving institutions, as well as a two-year college. a systems approach will be used to examine how elements of the educational context, such as size and departmental culture, influence instructor uptake and the resulting student learning. a mixed-methods research design will include the use of data analytics, instructor interviews, student focus groups, observations, classroom video, and pre/post concept inventory scores. the research plan will also address ways in which student backgrounds and demographics (e.g., underrepresented minorities; first-generation status) interact with institutional settings to affect student learning and engagement. workshops and faculty community building activities will be used to promote propagation of the enhanced evidence-based instructional practices. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Digitization TCN: Collaborative Research: Bringing Asia to digital life: mobilizing underrepresented Asian herbarium collections in the US to propel biodiversity discovery

Awardee: New York Botanical Garden

Amount: \$629,237.00

Abstract: Asia is the largest continent on earth, and includes the world's tallest mountains, lowest landscapes, and habitats ranging from arctic tundra to tropical rainforests and mangroves to deserts. The plants of this region are incredibly diverse in their identities and functions. More than one-third of the world's 350,000 plant species grow in Asia and include tiny alpine cushion plants, medicinal herbs, ancient crops, and some of the planet's tallest rainforest trees. But documentation of this **diversity** remains inaccessible and research about it is difficult because most herbarium specimens of Asian plants have not been digitized. The All Asia Thematic Collections Network (TCN) will mobilize online 15 million specimens of Asian plants currently housed in the US and around the world. The project will especially focus on digitizing specimens from the unique and critically endangered bio**diversity** hotspots of Southeast Asia and the Himalaya-Hengduan region. These mobilized digital data will accelerate research to conserve endangered plant species and understand the interacting effects of evolution and global environmental change on plant species **diversity**. The project will apply state-of-the-art informatics tools and high-throughput digitization methods to efficiently and affordably digitize an unprecedented number of herbarium collections. This effort will connect and build long-lasting relationships among 25 large and small consortium institutions in the U.S., Europe, and Asia. The focal areas from which specimens will be digitized encompass five bio**diversity** hotspots that include ~20% of the world's vascular plant flora and historically spanned 3 million km<sup>2</sup> of primary vegetation that now covers less than 300,000 km<sup>2</sup>. Fundamental bio**diversity** data for these bio**diversity** hotspots are lacking, along with the necessary baselines required to characterize species' identity, range, and responses to ongoing climatic change. The overall goals of the All Asia TCN are to rapidly digitize herbarium specimens of Asian plants to advance bio**diversity** discovery and provide critical baseline assessments essential for establishing floristic change in the Anthropocene. The project will accomplish this by (1) digitizing 3 million Asian vascular plant specimens from U.S. herbaria; (2) developing and applying

novel informatics tools and high-throughput digitization methods to massively scale herbarium digitization; (3) aggregating and mobilizing the digitized records from the project with those by international partners in china, france, the netherlands, and russia to establish a single online all asia portal of ca. 15 million specimens; and (4) enhancing opportunities for early career learners in science, technology, engineering, and mathematics by stimulating synergies between bio\*\*diversity\*\* and computer scientists who will use design thinking principles to create real-world informatics solutions to bio\*\*diversity\*\* challenges. to stimulate curiosity in plant \*\*diversity\*\* and botanical exploration among the general public, the consortium members will host several asia-themed notes from nature virtual expeditions to facilitate additional specimen digitization by citizen-scientists. digitized specimen data mobilized through this project will be shared and made available through idigbio.org. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: BRITE Relaunch: Manufacturing Multilayers of Molecularly-Bonded Inorganic Nanointerfaces for Accessing and Tuning Novel Properties

Awardee: Rensselaer Polytechnic Institute

Amount: \$627,998.00

Abstract: this award is funded in whole or in part under the american rescue plan act of 2021 (public law 117-2). nanocomposites ? which combine two or more distinct materials where at least one of the materials has dimensions of 100 nm or less ? are everywhere and are crucial for a wide variety of applications, ranging from automobiles, aircrafts and spacecrafts, buildings, sports equipment, travel packaging, to energy devices and electronics. the proportion of each material in a nanocomposite can be controlled to produce a composite material with properties that differ from each of the original components. a prominent goal is a combination that produces a material that is

both lightweight and has high mechanical strength. nanocomposites can also lead to extraordinary electrical or hardness properties that are not seen in the individual constituents. this boosting research ideas for transformative and equitable advances in engineering (brite) relaunch project aims to expand the boundaries of nanocomposite design and synthesis with a focus on these electrical and hardness properties. this project will advance the manufacturing process for these nanocomposites, expand knowledge and techniques related to the characterization of these materials, and develop models for the relationship between the structural variations and the properties so that they can be predicted and controlled through the manufacturing process. the knowledge gained will support the design and manufacturing of a new group of nanocomposites with properties that cannot be obtained from either conventional nanocomposites or natural biomaterials. this research will directly expose graduate and undergraduate students to multiple enriching collaborations with theorists and experimentalists in the usa and sweden. results from this work will enhance existing undergraduate and graduate courses on electronic properties, materials characterization and advanced structure. k-12 outreach efforts will include: engaging with high-school students and teachers; and supporting students from underrepresented sections of the society to encourage them to build careers in stem-related fields. mixing component materials in specific configurations allows access to property combinations that are not realized in individual materials, and the property enhancements are generally governed by the simple rules of mixtures. the researched work involves a merger of interface science, molecularly-engineered materials discovery, and nanomanufacturing. the overarching goal is to establish a platform for the manufacture of a completely new class of high-interface-fraction multilayered nanomaterials with inorganic nanolayers glued with organic nanolayers to realize unusual properties beyond the rules of mixtures. this includes materials with giant magnetoresistance and superhardness. such structures offer new possibilities to access, amplify and tune novel properties from superposition of effects from multiple nanoglued interfaces, and even realize a scenario wherein the interface properties become the materials' properties. manufacturing such nanocomposites with unprecedented

interface-dominated properties is anticipated to transformatively impact and expand the frontiers of a **\*\*diversity\*\*** of emergent technologies. specifically, this project will: synthesize nanoglued inorganic multilayers by hybrid atomic/molecular layer deposition techniques for different nanoglue structures and chemistries; characterize the thermal, chemical, and microstructural stability of the hybrid multilayers; unearth the effects of different facets of nanoglue structure and chemistry, and inorganic layer features, on mechanical and electrical properties; and develop models of nanoglue-induced property-enhancements to enable the realization of novel property combinations. the results are anticipated to open up new vistas for materials design and manufacturing beyond rule of mixtures, transcend crystallographically-constrained inorganic-organic hybrid materials, and facilitate synthetic materials and properties that are not accessible in current materials. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Using Whiptail Lizards to Understand the Integration of Environmental and Host Genetic Effects on Host-Associated Microbiota

Awardee: Clemson University

Amount: \$623,931.00

Abstract: animals, including humans, harbor large numbers of different microbes on and in their bodies ? so called host-associated microbiota. recently, scientists have begun to realize that host-associated microbiota are important determinants of host health. microbes in an animal?s gut, for instance, help digestion and can even help determine whether the animal is lean or obese. meanwhile, microbes on an animal?s skin can influence everything from wound healing to susceptibility to cutaneous disease. despite the importance of host-associated microbiota to host health, there is a surprising amount of variation in the microbiota on one host relative to another. how do these differences emerge? more specifically, are these differences a result of nature (i.e.,

host genetics) or nurture (i.e., host environment)? because most animals are genetically unique, it can be hard to determine whether inter-individual differences in host-associated microbiota are a result of host genetics, environment or both. in whiptail lizards, there are entire populations of genetically identical clones. what's more, these clones are closely related to other, sexually reproducing whiptail lizard species where each individual lizard is genetically unique. by comparing inter-individual variation in host-associated microbiota across different environments in clonal lizard populations versus sexually reproducing lizard populations, it will be possible to assess the relative importance of both host genetics and environment on host-associated microbiota. this research also provides an opportunity to train undergraduate students in research and scientific communication to help train the next generation workforce in stem. the strategy for this project is to use 16s rna gene sequencing to characterize and compare intraspecific variation in the bacterial and archaeal gut and skin microbiota of four hybrid parthenogenetic *Aspidoscelis* species and their bisexual parents. microbiota of each lizard complex (parthenogen + bisexual parent(s)), will be examined within a single vegetation community (low environmental variation), across different vegetation communities (intermediate environmental variation) and, for a subset of systems, across broad geographic ranges (high environmental variation). the first hypothesis is that variation will be smaller in parthenogens as compared to their bisexual parents. the second hypothesis is that inter-individual variation in lizard microbiota is driven by the environment, and that microbiome variation will be smaller at lower levels of environmental heterogeneity. determining the underlying causes of inter-individual variation in host-associated microbiota will identify rules governing host-associated microbial community assembly and, by extension, host health, fitness and ecological success. results from this work will have implications for both understanding microbial community assembly and guiding host conservation. as an example, knowledge of the factors that promote healthy host microbiomes will help to clarify trade-offs between preserving landscape **diversity** versus host genetic **diversity** during reserve selection. undergraduate students who are supported by this proposal will have the chance to perform research and to also develop

podcasts about biology research to broaden participation and to train students for careers in the sciences. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Algebraic Framework of Compositional Functions for New Structure, Training, and Explainability of Deep Learning

Awardee: University of Texas at San Antonio

Amount: \$622,955.00

Abstract: deep learning is a method of machine learning inspired by the human brain. data is fed to a multi-layered (deep) network of trainable 'neurons' and the network is then trained to model complex relations and processes. deep learning has had impressive success in applications such as image recognition and natural language processing. and yet, there are few theoretical guarantees to the method, to provide assurances in regards to performance features such as error and to explain its success. this is an impediment to broader application of deep learning, as many potential applications require guarantees for safety, reliability, and accuracy. this project pursues a solid mathematical foundation for a better understanding of the explainability of deep learning, to enable more efficient neural network design and training algorithms that benefit a wide range of applications. the project also includes a significant educational component that is designed to foster interdisciplinary education by engaging undergraduate and graduate students from the investigators' departments (applied mathematics, electrical engineering, computer science, mathematics) in the proposed multidisciplinary research. the project includes plans to promote **\*\*diversity\*\***, equity and inclusion in stem education at the university of california santa cruz and the university of texas at san antonio, which are both hispanic serving institutions. the overarching goal of this project is to develop a unified algebraic framework and approximation theory for deep neural networks so that the framework is applicable to a wide spectrum of problems including regression, solving differential

equations, designing optimal feedback control, and computer vision. the proposed research is motivated by the fact that most complicated and high dimensional input-output relations in real-world applications can be represented as compositions of simple low-dimensional functions. thus, compositional functions, including deep neural networks, serve as a natural way to describe complex high dimensional functions. representing compositional functions as layered acyclic graphs, the project will explore the compositional features of the problems to be solved by machine learning; study the error propagation in layered acyclic graphs; and investigate the interconnection between the compositional features and the fundamental issues of machine learning, such as the error bounds in universal approximation, deep neural network design and training, and validation and explainability. the algebraic framework, approximation theory, and computational algorithms to be developed in this research project should advance the design, training, and mathematical foundations of deep learning. they seek also to be directly applicable to a wide spectrum of applications including feedback control design and computer vision, which are included in this project, as well as other important machine learning applications, such as regression and data-driven modeling of dynamical systems. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: CAREER: Statistical Mechanics of Cellular Structures

Awardee: Northeastern University

Amount: \$622,756.00

Abstract: nontechnical summary this career award supports theoretical and computational research integrated with education to gain a unified understanding of the physical properties of cellular materials. from honeycombs to foams to biological cells, materials with cellular structures are ubiquitous in nature. to advance understanding of cellular materials, the pi will use an

interdisciplinary approach that combines knowledge and techniques from physics, geometry, and biology. organ surfaces are covered with dense layers of cells, acting as physical barriers. while normally non-migratory, cells can undergo active rearrangements during basic processes such as embryo development, morphogenesis, repair, and remodeling. in these events, the cell layer transitions from a solid-like state to a fluid-like state. this striking transition is traditionally studied in the context of cells on a flat surface. however, most organ surfaces are naturally non-flat, and comprised of curved surfaces such as spheres, saddles, or cylinders. how surface curvature affects cell motion remains largely unknown. to address these questions, the principal investigator will study how cells move collectively on a curved surface and the role of curvature on whether they behave like a solid or a fluid. these investigations will generate predictions that can be tested experimentally in living embryos and lab-cultured tissues. the knowledge gained from biological tissues will serve as an inspiration for the pi to investigate the origin of rigidity in other cellular structures. these include the meshwork of forces in a solid or a mechanical network constructed by randomly connecting springs. the goal is to develop design principles for cellular structures to exhibit unusual mechanical properties and take advantage of them to design functional materials that do not readily occur in nature. this career award also supports educational activities tightly integrated with the research. the goal is to increase **diversity** and retention of students taking physics classes for the very first time, whether in high school or college. the pi will collaborate with k-12 stem educators to design unconventional yet accessible teaching modules for introductory physics classes. the modules will be based on biophysics, epidemiology, and biology while drawing connections to the fundamental physical concepts taught in introductory physics. these modules, which differ greatly from conventional "textbook examples", will provide students an eye-opening experience on the applicability and impact of physics concepts. technical summary this career award supports integrated theoretical and computational research, outreach, and education with the aim to advance the fundamental understanding of the statistical mechanics and collective behavior of cellular materials, including biological tissues, foams, granular packings, and their force networks. in the

biological context, the project will investigate the nature of the jamming/unjamming transition in multicellular collectives constrained on a curved surface and elucidate the origin of coherent angular motion that arises as a unique consequence of non-zero gaussian curvature. in non-biological cellular structures, the pi will investigate the consequence of mechanical dualities. the objective will involve deriving an effective hamiltonian in the force space for disordered granular solids based on the dual correspondence between self-stress states and floppy modes. the framework will be the basis for exploring the force-network ensemble of disordered grain packings. the pi proposes to leverage the duality of self-stresses and floppy modes to design disordered mechanical metamaterials with phononic bandgaps. this career award also supports educational activities tightly integrated with the research. the goal is to increase **\*\*diversity\*\*** and retention of students taking physics classes for the very first time, whether in high school or college. the pi will collaborate with k-12 stem educators to design unconventional yet accessible teaching modules for introductory physics classes. the modules will be based on biophysics, epidemiology, and biology while drawing connections to the fundamental physical concepts taught in introductory physics. these modules, which differ greatly from conventional "textbook examples", will provide students an eye-opening experience on the applicability and impact of physics concepts. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: RUI:Test and Measurement Strategies for the Development of Biological Nanovalves

Awardee: Wheaton College

Amount: \$622,070.00

Abstract: with support from the chemical measurement and imaging program in the division of chemistry and co-funding from the interfacial engineering program in the division of chemical, bioengineering, environmental, and transport systems, dr. daniel burden, dr. lisa keranen-burden,

and their group in the chemistry department at wheaton college are developing a new set of laser-based tools that combine ultrasensitive microscopy with electrical measurements and protein engineering to monitor the movement of charged species through nanopores wherein protein toxins are used as nanovalves. their studies seek answers to questions such as what molecular sizes, shapes, and charge states are allowed to flow through the nanoscale valve interior, and what chemical modifications to the nanovalve are necessary to make it switchable on demand from the fully-on state to the fully-off state. the insights gained will likely be useful for a broad range of applications, including selective access to the interior of cells to fight infections, nanoscale separations, and chemical sensors. the research team is also working to enhance the size and **\*\*diversity\*\*** of the pool of qualified candidates for advanced stem degrees by investing in undergraduate research. elements of the research are integrated into the undergraduate curriculum, summer research opportunities, and public outreach activities in the surrounding community. measurement methods in ion-channel electrophysiology have traditionally been used to monitor the movement of charged species through nanopores. however, many translation events are electrically silent and cannot be detected. furthermore, an understanding of the sizes, shapes, charge states, and flow rates of species that can be transported (or blocked), as well as their relationship to nanovalve gating mechanisms, is critically important for developing future applications within the field. the burden group is investigating whether the alpha-hl toxin protein can be chemically modified to reversibly halt or permit molecular flow on demand. they also hypothesize that the size and rate of transported molecules will shift markedly upon triggered valve closure. they are developing measurement tools based on wide-field fluorescence microscopy, single-molecule confocal microscopy, and ion-channel electrophysiology to test a range of nanovalve constructs, with the ultimate aim of monitoring molecular transport across lipid membranes in a chip-based bilayer apparatus in real time. the pis are working with multiple undergraduate students, reaching out particularly to first-generation college-bound african-american or latino students from the chicago area. the pis are also actively working with outreach publishers to improve communicating research

outcomes to the public. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Belmont Forum Collaborative Research: Biosphere and Land Use Exchanges with Groundwater and soils in Earth system Models (BLUEGEM)

Awardee: Michigan State University

Amount: \$621,706.00

Abstract: this award provides support to u.s. researchers participating in a project competitively selected by a 9-country initiative on global change research through the belmont forum. the belmont forum is a consortium of research funding organizations representing over 55 countries focused on support for transdisciplinary approaches to global environmental change challenges and opportunities. it aims to accelerate delivery of the international research most urgently needed to remove critical barriers to sustainability by aligning and mobilizing international resources. each

partner country provides funding for their researchers within a consortium to alleviate the need for funds to cross international borders. this approach facilitates effective leveraging of national resources to support excellent research on topics of global relevance best tackled through a multinational approach, recognizing that global challenges need global solutions. this award provides support for the u.s. researchers to cooperate in consortia that consist of partners from at least three of the participating countries. the research teams will work to identify sustainable pathways to help alleviate the increasing and unprecedented pressure on the natural resources that interact to provide sustainable life support systems and essential benefits to societies such as food production and water quality and quantity. the impacts of changes in land management and urbanization will be evaluated to develop sustainable soils and groundwater management options that will help create and maintain sustainable terrestrial ecosystems. the project seeks to explore the evolution of groundwater, irrigation, and climate during the anthropocene (1900-2100), to better understand their interdependencies, foresee their potential changes, and identify possible social consequences. the team will assess these factors to identify sustainable pathways with respect to water resources, food security, bio\*\*diversity\*\*, and human well-being and socio-economic activities. the team will combine advanced numerical modeling of biophysical and social systems, as well as participatory methods with stakeholders, to address establish the fingerprint of interactions and irrigation on global and regional climate, water resources, biosphere, and soil carbon pools. the project results will provide improved projections of global and regional climate, water resources, biosphere and soil carbon pools, fully taking into account the influence of groundwater irrigation and groundwater-soil moisture interactions. the team will integrate local and regional knowledge and expertise as well as socio-economic data to refine the land use and irrigation scenarios used in state-of-the-art climate projections and to explore pathways for sustainable critical zone management. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: REU/RET Site: University of Hawai`i Institute for Astronomy

Awardee: University of Hawaii

Amount: \$620,829.00

Abstract: this research experiences for undergraduates (reu) program will offer individually mentored research experiences at the forefront of astronomical exploration to foster and enhance the careers of a diverse cohort of aspiring professionals in science, technology, engineering, and math (stem). the site will also include educators through the research experiences for teachers (ret) program. the institute for astronomy (ifa) at the university of hawaii reu/ret program will benefit society by training a diverse demographic in research skills needed in a stem career. they will achieve **\*\*diversity\*\*** by recruiting pacific islanders and minority students from professional organizations supporting african american, hispanic, and native american scientists. participants will learn about the impact that astronomical facilities have on indigenous people and the importance of communication between scientists and the public. progress towards achieving the desired societal outcomes will be assessed by conducting independent, external, quantifiable, surveys and interviews with the participants just before the program begins, at its mid-point, and after the program ends. many past students reported that this program was a key factor in their decision to attend graduate school or pursue a career in stem, and it is expected that new ret participants will multiply the program's effectiveness by bringing a modern astronomical research perspective to their classrooms. the method is based on past experience but will now be focused on diversifying the student demographics through targeted recruitment and restricting the program to students from non-research universities and colleges. with 50 mentors pursuing a broad range of astrophysical research, the participants will be immersed in the ifa's world-class research environment. the experience will also include activities that promote professional development. participants will visit observatories on mauna kea, complete research projects based on data from these facilities and participate in observations. in addition to the mentoring process, students will participate in a stem-specific professional development course

providing background and skills required for a stem career. a set of reports in the form of a research paper serves to develop the participants' writing skills. finally, the participants develop their presentation skills by preparing poster and oral presentations and then giving them to broad audiences. the participants are supported to present their research in poster or oral form at a professional meeting after the program ends. in the long term, the program will advance knowledge by sparking a lifelong pursuit of knowledge in a stem career in participants who will then bring their renewed excitement to their classrooms. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Transitioning MorphoBank to a sustainable, permanent home for phenotypic data in phylogenetics research

Awardee: Phoenix Bioinformatics Corporation

Amount: \$617,216.00

Abstract: scientists use the tools of phylogenetics to study this **\*\*diversity\*\*** and ask questions about how species evolve and how they are interrelated. such research addresses fundamental questions about the characteristics of living organisms, and helps scientists and the general public understand when, where and how traits like flowers and behaviors like the ability to fly first arose. such questions can be answered by collecting data on the detailed morphology, anatomy or other traits of the phenotype of many different species, organizing the data into ?matrices? and using the data to build phylogenetic trees that reconstruct evolutionary changes over time. these matrices and phylogenetic trees are the foundation for new discoveries in a wide range of scientific disciplines including animal and plant biology, bacteriology, anthropology and paleontology. morphobank is the only web-based software package for this work, and before it existed, researchers built matrices on their personal computers, a practice that limited the ability to collaborate and communicate, and to

disseminate and reuse data. because morphobank serves as an archive as well as a research tool, this software allows phylogenetics research to advance more quickly by facilitating the combination of old and new data. morphobank guarantees that integrated data are readable by both computers and humans and makes its data freely available to anyone worldwide, thereby opening up a new avenue for the public to access the direct products of scientific research. morphobank is a broadly used community tool to support basic biological research. recognizing that the tool must be sustained long term, in 2018 morphobank began the transition from grant-based support to a sustainable membership-based financial model in partnership with the non-profit scientific database organization, phoenix bioinformatics. over the next three years morphobank's leadership team will complete a transition to full membership support. morphobank will do this by growing its membership support from university libraries and museums while maintaining the core software and continuing to serve a growing us and international research community. the award will support software maintenance, data curation and scientific leadership, while morphobank ramps up its membership support sustainability plan. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Demand-driven science: the role of knowledge partnerships in improving the public value of conservation science

Awardee: Arizona State University

Amount: \$616,784.00

Abstract: in recent years, conservation scientists have recognized the importance of partnerships with stakeholders outside of academe to innovate and realize measurable conservation outcomes. knowledge partnerships represent a form of knowledge production that can advance public value outcomes. while public value is an important concept in science and innovation policy research and

management, there is little research on how partnerships between institutions can deliver public value, especially in conservation science. we propose to study how and when the supply of and demand for conservation knowledge are linked. in particular, we seek to examine, 1) what are the mechanisms by which the demand for knowledge informs the production and supply of science in conservation?; 2) what role do knowledge partnerships play in linking the supply of and demand for conservation knowledge, and what effect does the design of these partnerships have on their ability to deliver public value?; and 3) how can research projects and knowledge partnerships be designed to avoid public value failures, improve the connection between the production and use of science, and thus increase the public value of scientific activity? our proposed research builds on our recent work on determinants of the supply of public value outcomes in conservation science. by analyzing experiences of knowledge users and the possibilities inherent in knowledge partnerships as a distinct organizational form, we aim to understand the organizational configurations best suited for facilitating demand-driven conservation science. our proposed research will provide a model and tools for achieving and enhancing public value outcomes in conservation science and related fields. the identification of indicators of public value success is directly translatable and adaptable to governmental, private and non-profit organizations. this research will provide guidelines on how to design knowledge partnerships for public value and will offer new models of institutional partnerships to address complex social and ecological aspects of bio\*\*diversity\*\* conservation, thus enabling solutions that are relevant, culturally sensitive, economically viable and nimble. our proposed research will provide an evidence-based approach for maximizing public value outcomes in the production of conservation science. realizing public value outcomes in research entails structuring scientific research collaborations to meet established knowledge needs rather than producing knowledge for which there is no demand. public value outcomes in research also entails structuring institutions to provide incentives for public value outcomes; and structuring and scaling research programs and collaborations for impact based upon approaches documented to have the best potential for success. in examining the communication and translation processes that link

knowledge users to knowledge producers, we will focus specifically on those who often have not been included in these processes. with public value creation as the guiding principle, we will uncover lessons for the design of research projects, partnerships and knowledge-producing organizations. we will produce a framework for understanding how the processes of scientific research can be transformed to be more inclusive of stakeholders and improve the connection between the production and use of science, thus increasing the public value of scientific activity. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: BRITE Pivot: Tissue Research Advances for New Surgeries-Facilitating Organ Reconstruction with Mechanics

Awardee: Virginia Polytechnic Institute and State University

Amount: \$615,998.00

Abstract: this boosting research ideas for transformative and equitable advances in engineering (brite) pivot project will develop tissue mechanical property data and advanced computer modeling approaches to improve surgeries specific to transgender people. this work will mechanically characterize tissue from human genitalia. this work will leverage the researchers' existing expertise in evaluating the mechanics of soft tissues, such as ligaments and tendons. specifically, this work will make a computer model of how these tissues behave at the microscopic level based on data from measurements of actual tissue. the model will be used to evaluate differences among genital tissues of all genders. this work will improve our understanding of reproductive biomechanics of all persons. the results may ultimately improve healthcare by including this engineering assessment of tissue properties in surgical planning and procedures, including gender confirmation surgeries. this project will also promote inclusion in the engineering biomechanics research community through dialogue about conceptualization of gender, both within research and within the research

community. this research focuses on providing the first scientific-based data for gender confirmation surgeries that alter the genitalia of individuals with gender dysphoria to conform to their desired gender. state-of-the-art mechanical testing will be conducted on tissues from human genitalia to fully characterize their elastic and viscoelastic properties that are crucial for the success of surgeries including those for gender confirmation. novel mathematical and computational models will be developed to capture both the similarities and differences between male and female genitalia. through this brite pivot project, the principal investigator will gain new expertise in advanced numerical techniques for reducing the computational complexity of numerical simulations for gender confirmation surgeries. efficient and robust computational tools will lead to the development of novel engineered tissues and guidelines for gender confirmation surgeries, addressing the extant healthcare challenges of transgender people. the outcome of this project will thus promote gender **\*\*diversity\*\*** and equality in medical research while also changing the assumption of binary genders in the research community. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Redefining the footprint of deep ocean methane seepage for benthic ecosystems

Awardee: California Institute of Technology

Amount: \$615,832.00

Abstract: this research examines the role of deep-sea organisms in determining the fate and footprint of methane, a potent greenhouse gas, on pacific continental margins. the investigators are evaluating the deep ocean methanosphere defined by the microbial communities that consume methane and the animals that directly feed on or form symbioses with methane-consuming microbes. they are also investigating animal communities that gain energy indirectly from methane,

as well as those that take advantage of carbonate rocks, the physical manifestation of methane consumption in seafloor sediments. the study of methane seeps in the deep waters of both alaska (4400-5500 meters) and southern california (450-1040 meters) is enabling comparisons of the methanosphere under different food-limitation and oxygen regimes. by applying diverse chemical, isotopic, microscopy, and genetic-based analyses to seep microbes and fauna, this study is advancing understanding of the contribution of methane to deep-sea bio\*\*diversity\*\* and ecosystem function, information that can inform management and conservation actions in us waters. in addition to training for graduate and undergraduate students at their home institutions, the investigators are collaborating with the alaska native science and engineering program (ansep). they are recruiting alaskan undergraduates to participate in the research, contributing to ansep's online resources that promote interaction between scientists and middle and high school students, and participating in ansep's annual residential career exploration in marine science programs to engage middle school students in learning about deep-sea ecosystems and the variety of career pathways available in marine related fields.

microbial production and consumption of methane is dynamic and widespread along continental margins, and some animals within deep-sea methane seeps rely on the oxidation and sequestration of methane for nutrition. at the same time, understanding of methane-dependent processes and symbioses in the deep-sea environment is still rudimentary. the goals of this study are to 1) examine the \*\*diversity\*\* of animals involved in methane-based symbioses and heterotrophic consumption of methane-oxidizing microbes and how these symbioses extend the periphery of seeps, contributing to non-seep, continental slope food webs; and 2) determine whether carbonates on the seep periphery sustain active methanotrophic microbial assemblages, providing a localized food source or chemical fuel for thiotrophic symbioses, via anaerobic oxidation of methane, or free-living, sulfide-oxidizing bacteria consumed by animals. the investigators are addressing these goals by surveying, sampling, and characterizing microbes, water, sediments, carbonates and animals at a deep seep site on the aleutian margin and a shallow site off southern california. shipboard experiments and laboratory analyses are using molecular,

isotopic, geochemical, and radiotracer tools to understand transfer of methane-sourced carbon from aerobic methanotrophs under multiple oxygen levels, pressures, and photosynthetic food inputs. this approach offers a wide lens by which to examine the methane seep footprint, allow reinterpretation of past observations, and identify new scientific areas for future study. improved characterization of the deep continental margin methanosphere informs climate science, bio\*\*diversity\*\* conservation, and resource management. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: CAREER: Temporal dynamics of microbial and viral function and adaptation in hydrothermal vents

Awardee: Carleton College

Amount: \$614,024.00

Abstract: this award is funded in whole or in part under the american rescue plan act of 2021 (public law 117-2). this project is funded by the biological oceanography and the ocean education programs (division of ocean sciences) and the systematics and bio\*\*diversity\*\* science cluster (division of environmental biology). microbes and viruses living near deep-sea hydrothermal vents act as filters for carbon, sulfur, iron, and other essential elements that emerge from the seafloor and flow into the global oceans. however, due to the challenges associated with sampling the deep sea, most studies to date have captured only snapshots of these communities, leaving significant knowledge gaps about how microbes and viruses adapt, evolve, and respond to changes in this environment. the researchers use infrastructure from the ocean observatories initiative to conduct high-resolution monitoring of genetic changes over five years to investigate microbial communities? function, ecology, and evolution at hydrothermal vents, which are thought to be one of the most ancient habitats on earth. data from this project are expected to be a valuable scientific resource for these

and other researchers to address future questions. for example, it will inform our understanding about the early evolution of life on earth and how microbes and their viruses respond to anthropogenic disturbances like deep-sea mining and climate change. this project engages and trains undergraduate students as scientific partners at all stages of the research process, facilitating their entry into scientific networks. additionally, a new course guides college students in examining science within its cultural, political, and social context. the project also includes a program with a local elementary school to increase science literacy among young students. the main objective of this project is to understand the ecological and evolutionary forces that mold hydrothermal vent microbial and viral populations over time. this project uses instruments from the ocean observatories initiative regional cabled array (ooi rca) at axial seamount in the northeast pacific ocean to collect hydrothermal fluid and dna samples at regular intervals, approximately every 10-20 days over five years, to yield a time series of microbial and viral abundances and metagenomes. the specific scientific aims of this project are to: 1) identify environmental drivers of microbial community composition and function through time-series analyses of 16s rrna amplicon and metagenomic datasets combined with chemistry, ph, and temperature data; 2) use single nucleotide variant and gene content variation over time in metagenome-assembled genomes to investigate evolutionary dynamics of microbial populations; and 3) assess models of viral population dynamics by tracking micro\*\*diversity\*\* within viral and microbial metagenomes over time. comparative samples and data collected from other vent sites are used to determine the generalization of the results. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Excellence in Research: From genomics to ecophysiology: the adaptive metabolic strategy of heterotrophic marine *Cyclobacterium* species

Awardee: Hampton University

Amount: \$613,265.00

Abstract: the majority of microbial bio\*\*diversity\*\* in the ocean lies within the realm of the rare biosphere. these rare microbes are essential for ecosystem dynamics and play a central role in the carbon cycle from assimilation, storage, transformation, export, and remineralization of the largest pool of organic carbon on the planet. the members of bacteroidetes, are emerging as key players in the degradation of high molecular weight dissolved organic carbon (dom). in this research project, *cyclobacterium marinum atlantic-is*, a member of bacteroidetes and part of the rare biosphere, will be studied to determine how *c. marinum atlantic-is* adjusts its growth in response to different dom present in the marine environment. this project will examine how *c. marinum atlantic-is* adjust its growth in response to different dom present in the marine environment and thus will enhance the understanding of microbial degradation of complex carbohydrates and the molecular processes involved in the usage of different organic carbons. this research has implications for understanding functional ecological significance of rare bacterial taxa in ocean ecosystems. this study actively engages undergraduate students of color. students will gain knowledge and skillsets spanning molecular biology methods, microbial physiology, and quantitative data analysis. this training will contribute to student retention in stem, increase \*\*diversity\*\*, and workforce development. this project will strengthen research capabilities of the principal investigator and build research capacity at a historically black college and university (hbcu). a partnership between the hbcu and woods hole oceanographic institution will be established. the annotated draft genome of *c. marinum atlantic-is*, which was collected from benthic water of the atlantic ocean, contains higher than expected number of polysaccharide utilization genes, hydrolases, and transport-related proteins that would allow the bacterium to survive under famine conditions and bloom when dom is abundant. in addition, it contains a large number of regulatory genes, which could be pivotal for the generation of swift and adaptable metabolic responses to changing dom in the environment. the principal investigator will test the hypothesis that *c. marinum* with its large number of polysaccharide utilization genes, transporters, and regulatory genes is able to adapt to changing carbon sources in

oligotrophic oceans. this hypothesis will be tested by combining transcriptomics, proteomics, and physiological approaches to understand the expression of various transporters and regulatory networks that trigger the use of select polysaccharides and polymeric glycans thought to be abundant in the ocean. in particular, the expression of numerous transporter systems in response to different carbon sources and the speed of response to changing carbon sources will be determined. ultimately, this research will enhance the understanding of heterotrophic bacteria in the ocean and their ecophysiology. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: ATETV presents: Technician Navigator

Awardee: Pellet Productions, Inc.

Amount: \$611,023.00

Abstract: in its 2019 report on the skilled technical workforce, the national science board noted that skilled technical workers represent 13% of the u.s. workforce aged 25 and older. furthermore, these workers "contribute to all parts of the economy and the science & engineering enterprise" by exercising "critical thinking, design, digital, math, and coding skills to work as auto mechanics, health care technicians, electricians, welders, computer systems analysts and administrators, and operators of "smart" infrastructure." this project will bring awareness to the educational pathways leading to work and career opportunities in the skilled technical workforce, bolstering connectedness among ate students - and more generally all students in the two-year sector, educators, and industry stakeholders. a stem-capable and competitive workforce leads to innovation, success in industry, new discoveries in research and development, and advancements in stem achievements. this ultimately yields a more economically prosperous nation, renewed global competitiveness, and greater economic security and prosperity, all of which are goals of the ate program. technician navigator will produce an atetv repository of authentic original content produced by current practicing technicians for future technicians that will include blogs, videos, audio materials, and forums. these materials will inform and engage students, families, and educators. through virtual events and one-on-one sessions developed by faculty and industry representatives, technicians will guide prospective students through the college decision-making process, supporting them through enrollment. creating contextual experiences to increase the quality, quantity, and **\*\*diversity\*\*** of a skilled technical workforce is at the heart of this project. contextual experiences meet prospective students where they are instead of trying to attract their attention, and then use a series of connected experiences that incrementally guide them along their journey to enrolling in technician education programs at community and technical colleges. this will be a first-of-its-kind experiential resource designed to attract and recruit students into technician education programs and walk them through the process of enrolling in technician education programs. it is expected that technician

navigator will serve the ate community as a tested model for student recruitment with digital tools and resources for use in other ate community outreach efforts. content and contextual experiences will establish a community, connect people and programs, and generate excitement and interest through authentic materials and experiences. this project is funded by the advanced technological education program that focuses on the education of technicians for the advanced-technology fields that drive the nation's economy. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: New Approaches to Catalyst Screening and Development

Awardee: University of Nebraska-Lincoln

Amount: \$607,249.00

Abstract: this research project builds on a platform being developed by the university of nebraska research team to exploit enzymes as catalytic reporters to facilitate reaction discovery and catalyst optimization. this approach is termed in situ enzymatic screening. the method utilizes "reporting enzymes" to provide real-time information on the relative rates for a set of parallel organic/organometallic reactions of interest. parallel screening methods are of interest to chemists in academia and industry as they enable the identification of fundamentally new transformations of novel catalysts for targeted reactions. there is a particular need for focused screening in process chemistry groups in the pharmaceutical industry, where reaction optimization is critical. this project seeks to develop new enzymatic screening tools that are applicable across a range of temperatures and that take advantage of phosphate ester functionality for which enzymatic screens are not yet available. the project will also help build the future stem (science, technology, engineering, and mathematics) workforce by training a diverse group of undergraduate and graduate students in an interdisciplinary research environment at the chemistry/biology interface, including elements of

organic, organometallic, analytical, and enzymatic chemistry. this project will further explore and develop an information-rich parallel screening method, termed in situ enzymatic screening (ises), that uses enzymes as biomacromolecular sensors to provide read-out directly to the experimentalist. this research builds upon the team's earlier proof-of-concept studies that led to the first examples of catalytic asymmetric allylic amination chemistry with nickel, an earth-abundant metal, and that uncovered a useful new transformation for **diversity**-oriented synthesis known as thiocyanopalladation/carbocyclization. this proposal seeks to fully launch the "phosphate-ises" and "thermal-ises" screening platforms. the former goal is motivated by the emergence and importance of substrates bearing dialkyl phosphate functionalities, an important functional group both for transition metal coordination and for specific chemistry. these new enzymatic screening platforms have been built by expressing and testing candidates for screening enzymes that recognize dialkyl phosphates and/or that operate at elevated temperatures. preliminary results point to enzymes that produce a uv/vis signal under such conditions, enabling the screening of candidate metal-ligand combinations at elevated temperatures or in reactions where dialkyl phosphate functionalities are critical. these methods are being developed with specific targeted chemistry in mind, particularly the catalytic asymmetric synthesis of alpha-halovinyl amino acids as potential mechanism-based inhibitors for plp (pyridoxal phosphate) enzymes. this synthetic goal builds on recent developments in this laboratory in which quaternary, alpha-(1-fluoro) vinyl amino acids were synthesized for the first time. the scientific broader impacts of this work include opening new avenues for the catalyst discovery process and for green and sustainable chemistry. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Edge CMT: Polygenic traits of heat stress phenome in coral "dark genes" from genome to functional applications

Awardee: Carnegie Institution of Washington

Amount: \$603,400.00

Abstract: in this project, the researchers will use genomics, genetics, and cell biology to understand the function of coral genes during heat stress. thermal stress often causes the "bleaching" (whitening) of corals that is harming reefs worldwide and is a threat to marine biodiversity. genes are the functional unit of dna and how the coral reacts to heat stress is called its phenotype. there are many genes involved in achieving the heat response phenotype and they will be studied in this project. this is important because the function of many of these and other genes and how they influence the phenotype of corals are not understood. in addition, many of the coral stress genes are unknown in other organisms (i.e., they arose in corals), and therefore present the opportunity to discover the function of novel genes. this research is important because it will help in the understanding of how both known and novel genes function, which can aid in the conservation of coral reefs- a resource that is important for national security and economic growth. lastly, this project will fund early career scientists and lead to broader impacts through the training and education of a diverse workforce in science. the overarching goal of this proposal is to determine the mechanistic drivers of the stress response in multicellular organisms, with a focus on the ecologically important corals. to achieve this goal, application of an end-to-end approach that extends from genes to phenotypes, to cell biology, using multi-omics and network methods with both holobiont and single cell data will be applied. this work will elucidate the coral stress phenome in species with differing reproductive strategies and geographical origins to determine the functions of both known and unknown (dark) genes. generating this knowledge base will transform coral biology and more broadly, provide a research platform for testing hypotheses about the resilience of other ecosystems, marine and terrestrial, which is particularly important under accelerating climate change. this project aims to increase the understanding and predictive capability of how key properties of living systems emerge from the interaction of genomes. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's

intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Testing the reduction of aerobic habitat as a common kill mechanism for major mass extinction events

Awardee: Stanford University

Amount: \$602,541.00

Abstract: the project will study the response of marine animal ecosystems to environmental change using three mass extinction events from the geological record as study systems. specifically, the project will test the hypothesis that a large proportion of extinction during these events can be explained by the stresses that elevated temperatures and reduced oxygen availability place on animal respiration. geochemical data will be used to constrain computer simulations of changing ocean conditions during these mass extinction events. results from laboratory studies on animal respiration will then be paired with fossil data to assess whether differences in extinction intensity in space and across taxonomic groups can be explained by spatial variation in environmental change or differences among taxonomic groups in their ability to withstand environmental change. the project will provide interdisciplinary training to a group of graduate students and post-docs. it will further impact stem education through the creation of a website that will allow access to model results so that students can visualize and explore model output to understand cause-effect relationships between continental configuration, ocean conditions, and biological **\*\*diversity\*\***. the investigators will also offer short-courses on earth system modeling and data interpretation at major conferences that will be recorded for asynchronous use. the project will also involve the development of a podcast series addressing how we reconstruct the ancient earth system and use these reconstructions to better understand the present and predict the future. in this project, the hypothesis will be tested that the loss of habitat through constraints on aerobic respiration under climate change and ocean deoxygenation can explain the magnitude, taxonomic selectivity, and

latitude variation in intensity for the late devonian (frasnian-fammenian), end-permian, and end-triassic mass extinction events. paleoredox and paleoclimate proxy data and geochemical indicators of diagenetic alteration will be used for both global average and local conditions before and after each major event combined with predictions from earth system models and occurrence data from the fossil record of marine animals to separate aspects of extinction that can be explained by physiological stress from those that require other explanations. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: LTREB Renewal: The reorganization and resynchronization of biogeochemical cycles after an unprecedented tundra fire

Awardee: University of Notre Dame

Amount: \$600,000.00

Abstract: fire has been historically rare in the arctic tundra, but is projected to increase in severity and frequency in a future warmer world. the rarity of fires in this biome has made it challenging to measure, understand, and predict the consequences of fire on important ecosystem services such as species **diversity** and ecosystem carbon cycling. furthermore, the impacts of fire last a long time-- years to decades-- by altering critical biogeochemical cycles that are important for long term ecosystem recovery. since fire severity can dramatically reduce soil nutrient availability, it is hypothesized that ecosystem recovery is dependent on both burn severity and post-fire soil resources. this project continues a ten-year project studying the effects of fire on terrestrial carbon cycling in alaskan tundra ecosystems. the research combines long-term ecological observations, a nutrient addition experiment, and improvement of an ecosystem model. training and workforce relevant skills for both undergraduate students and graduate students are being provided. a children's book will be published to reach the general public, as well as a youtube video. a large

amount of data about ecosystem processes is being contributed to public databases. this research will acquire and synthesize a multi-decadal record (2008-2026) of ecosystem function from the unprecedented 2007 anaktuvuk river fire on the north slope of alaska. eddy covariance fluxes and biomass harvests will measure temporal changes in ecosystem carbon fluxes and stocks across a burn severity gradient (severe-, moderate-, and un-burned tundra), while nutrient fertilization experiments at the severe- and un-burned tundra sites will determine the role of nutrient availability on the rate of ecosystem recovery. these records will inform a coupled biogeochemical model (i.e. the multiple element limitation [mel] model) to improve predictions of the long term impacts of fire on arctic ecosystem carbon cycling. the development of the mel model will provide a powerful tool for scientists, land managers, and policy makers to quantify the future impacts of fire in this rapidly-changing region. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: III: Medium: Collaborative Research: Self-Supervised Recommender System Learning with Application Specific Adaption

Awardee: University of California-Davis

Amount: \$600,000.00

Abstract: in the era of big data, to effectively help people get their desired information, recommender systems are widely adopted by various online platforms. recommender systems aim to provide users with high-quality recommendation services. in addition to e-commerce, other potential applications include precision medicine to recommend targeted patient treatment, friend recommendation in online social networks, decision support, e-learning, etc. however, various data quality problems and model learning challenges will create great obstacles for recommender system deployments in the real world. to address these challenges, this project explores to develop new

techniques for learning recommender systems that don't rely on supervision information like manual label or annotation, which can be costly to obtain. this is referred to as the recommender system self-supervised learning, which provides a promising learning paradigm that can discover the supervision signals from the data itself without the need of costly manual annotation. as an effective technique, self-supervised learning will enable recommender systems to work well in a variety of challenging application scenarios to provide people with high-quality and fair recommendation services for almost all the existing online platforms mentioned above. this project focuses on developing a general recommender system framework with self-supervised learning, and investigating its various extensions. this project will develop unified and extensible principles, methods, and technologies for recommender system learning, and study the general applicability and benefit of recommender system self-supervised learning. the recommender system tasks studied in this project are extremely challenging due to many reasons: (1) lack of supervision information, which renders many existing recommendation models to be ineffective; (2) inherent data biases, which can lead to unfair treatment to the minority user groups; (3) the cold-start problem, which concerns on the issue of inferences for subjects with little collected information; and (4) recommender system dynamics, which reflects the changing characteristics or behaviors of the users. this project will address these challenges on learning representations for recommender systems with a novel and extensible graph neural network model. based on the state-of-the-art self-supervised learning techniques, e.g., data augmentation which aims to significantly increase the **diversity** of data available for training models without actually collecting new data, and contrastive learning which intends to learn succinct data representations such that similar samples stay close to each other, while dissimilar ones are far apart, the proposed model can be pre-trained with self-supervised learning, which will be further transferred to address the problems studied in this project via effective fine-tuning. specifically, this project will focus on studying four main tasks: (1) fairness-oriented recommender systems pre-training and fine-tuning, (2) cold-start recommender system learning via data augmentation; (3) inter-platform recommender system contrastive learning;

and (4) lifelong dynamic recommender system learning via self-supervised model tuning. in terms of broader impacts, besides the recommendation tasks as investigated in this project, advances in such research studies have transformative potentials for fundamental development in reforming the current and future ai model fairness, trustworthiness, and lifelong learning studies in broad applications. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Gravitational Wave Transient Astrophysics with LIGO

Awardee: Georgia Tech Research Corporation

Amount: \$600,000.00

Abstract: in the five years since the historic discovery of gravitational waves unlocked the dawn of a new kind of astrophysics, gravitational waves have continued to probe the cosmos and reveal some of the most obscure mysteries of the universe. according to the theory of general relativity,

gravitational waves are tiny oscillations of the curvature of space-time produced by the acceleration of massive astrophysical objects, such as colliding black holes or neutron stars. the information these waves carry is different and complementary to that of photons, neutrinos and cosmic rays -- this is the era of multi-messenger astrophysics. the nsf-funded laser interferometer gravitational-wave observatory (ligo) is currently the most sensitive gravitational wave-detector in the world. following its first discovery of gravitational waves in 2015, ligo and its sister project virgo together have now detected dozens of binary black hole collisions, and are exploring the origins and nature of black holes that were once only theorized about. the landmark 2017 multi-messenger observation of binary neutron star (bns) merger gw170817 yielded a wealth of additional discoveries, and has prompted the field to grow at an even more rapid pace. this award supports ligo science performed at the georgia institute of technology for the detection, characterization and astrophysical interpretation of gravitational-wave transients in ligo data, towards a new frontier in science and a deeper understanding of the universe. the team supported by this award has a long record of contributing to mission-critical tasks and publications of the ligo scientific collaboration, and will continue to engage in core ligo science through a combination of morphology-independent techniques, template-based approaches, and multi-messenger strategies. the team will enable ligo science by developing data analysis infrastructure, studying the impact of data quality and participating in the analysis of candidate events using three algorithms in use by the ligo scientific collaboration: bayeswave, a model-independent code for waveform reconstruction and event characterization; rift, a code for rapid parameter inference using template families and numerical relativity waveforms; and pygrb, for the detection of coincidences with astrophysical events such as gamma-ray bursts. the team will also explore novel approaches for understanding special astrophysical targets, such as neutron-star post-merger events, black hole hyperbolic encounters, and coincidences with neutrino events. the award will benefit from the collaboration of a synergistic team at the georgia tech center for relativistic astrophysics which includes experts in computational astrophysics, cosmology, particle astrophysics, astronomy, the college of computing, a strong

outreach program in atlanta enhanced by the ties to the ligo scientific collaboration, and a firm commitment to **\*\*diversity\*\***, equity and inclusion and the engagement of women in stem. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: SaTC: CORE: Medium: Making Crypto Too BIG To Break

Awardee: Northeastern University

Amount: \$600,000.00

Abstract: this project aims to build new cryptosystems with strong security guarantees, by making the secret keys and/or communication large. the unifying technique is to overwhelm the adversary with information to ensure that it cannot store enough of it to break the scheme, even given significantly more resources than the honest users. the project's novelties are new cryptosystems where: (1) security holds even if an adversary compromises the machine storing the secret key and exfiltrates large amounts of data, (2) security does not rely on any unproven mathematical assumptions, but instead just requires either a large key, or large amounts of communication between the honest participants. the project's impacts are: (a) the design of more secure systems in the real world, (b) synergizing, unifying and abstracting techniques from many diverse areas of computer science, and (c) mentoring undergraduates, graduate students and postdocs with an emphasis on fostering **\*\*diversity\*\***. the design of cryptographic schemes and protocols traditionally strives to make secret keys and communication as small as possible. in this project, the investigators argue that there are several important settings where it is possible to dramatically improve security by making secret keys and/or communication large, while still allowing the resulting scheme to be quite practical. the project focuses on three such settings. the first setting considers an adversary who breaks a cryptographic scheme by outright stealing the corresponding secret key. a promising approach to mitigate against such attacks is to make cryptographic keys intentionally

huge, to prevent an adversary from exfiltrating them in their entirety. this project suggests novel research directions towards bringing such schemes closer to reality. the second setting studies cryptosystems with information-theoretic (it) security, that are provably secure even against attackers with unlimited computational power. while such cryptosystems are known to require a large key, the project studies how to make them practical by ensuring that they are stateless and read only small portions of their large keys at every use. the third setting studies it-secure protocols, where the protocol communication is made intentionally large, so that it becomes infeasible for the attacker to store it all. the honest participants process the communication in a streaming manner using much less storage than the adversary. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Abstract: the need for a highly skilled cybersecurity and it workforce is well documented and unequivocal. ?demand for security skills, once limited primarily to government and the defense industry, has spread throughout the economy? (burning glass, 2019). ?job growth is predicted to

continue to outpace the number of available qualified workforce? (cyberseek.org, 2020). community and technical colleges respond to this need through their education of the skilled technical workforce. this project aims to strengthen and grow a specific component of that workforce, namely the nation's cybersecurity/computing professionals. the project's approach is to work to increase the quality of the requests for external support that these institutions seek to improve cybersecurity education at their campuses. towards this end the project investigators plan to attract a **\*\*diversity\*\*** of community and technical college teams, composed of faculty, grant writers, and selected administrators and staff and provide team-based professional development designed to increase the competitiveness and innovativeness of each teams' proposed efforts in support of the education of the cybersecurity/computing skilled technical workforce. in each year, up to twelve community and technical college teams of two faculty members and a grant writer will be accepted through an application process to participate in this team-based professional development and mentoring program. each team will be carefully matched with and supported by a seasoned mentor who has been trained through a series of coaching sessions by the leadership team. essential elements of the program, including mentor training, pre-workshop mentee preparation, a multi-day workshop, and post-workshop webinars coupled with team mentoring throughout the entire process, are designed to help participants crystalize their innovative ideas and develop competitive proposals for external support. this project is funded by the advanced technological education program that focuses on the education of technicians for the advanced-technology fields that drive the nation's economy. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: RI: Medium: Submodular Information Functions with Applications to Machine Learning

Awardee: University of Texas at Dallas

Amount: \$599,594.00

Abstract: a growing number of machine learning applications involve selecting subsets of data. examples include selecting smaller subsets from a much larger dataset to label (to save labeling costs) and to train (to reduce computational costs), or selecting a summary of a video or a photo collection to ease viewing by a person. submodularity is a natural way to address these problems because it naturally models many aspects like **diversity**, representation, and coverage. in this project, the pis will study a rich class of submodular information measures that model not only **diversity**, representation, coverage but also constructs such as relevance and irrelevance to certain target concepts. one application of this is selecting a data summary with certain user specifications -- e.g., a summary relevant to a given query or under a privacy constraint (a photo summary relevant to a specific person or one which avoids certain personal information). another application is to interactively select data samples to label in the presence of rare classes or while avoiding outliers (e.g., cancerous images as rare classes for medical imaging tasks). advances in this field can have implications in many areas including data summarization, reducing labeling efforts (in tasks like medical imaging), and reducing the carbon footprint for training deep learning models on massive datasets. the underlying mathematical model proposed in this project is a rich class of functions called ``submodular information measures``, which includes submodular mutual information, submodular conditional gain, submodular multi-set mutual information, directed submodular mutual information, and combinatorial independence. specifically, the pis will investigate and develop: (1) rich theoretical properties and instantiations of these submodular information measures; (2) optimization algorithms, approximation bounds, and hardness results of the associated optimization problems; (3) applications of the submodular information measures in data summarization, data subset selection, active learning, clustering, and diversified partitioning. while pursuing these activities, the pis will involve undergraduate and under-represented high-school students in this research to inspire them to pursue careers in ai/ml and other stem-related fields. this award reflects nsf's statutory mission and has been deemed worthy of support through

evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: CAREER: Deconstructing the Fitness Tradeoffs that Limit Viral Host Range

Awardee: North Carolina State University

Amount: \$599,448.00

Abstract: this award is funded in whole or in part under the american rescue plan act of 2021 (public law 117-2). this research project will explore how viruses adapt to multiple host species. viruses have a remarkable capacity to adapt to novel environments, but their potential to infect new hosts is not necessarily limitless. adapting to a novel host is largely thought to decrease pathogen performance or fitness in other hosts, limiting the range of hosts a given pathogen can infect. understanding how these tradeoffs could therefore provide major insights into how best to control and manage viral pathogens. this research project will develop new computational methods to estimate pathogen fitness across different environments and scales. these methods will be applied to study viral fitness tradeoffs in tomato spotted wilt virus (tswv). tswv is a major pathogen of several important crops and its wide range of plant hosts has allowed it to become a major agricultural threat worldwide. in addition, the project will involve undergraduate and graduate students in the research, and develop a virtual environment in which students can interact and respond to a series of simulated epidemic threat scenarios. studying how tswv adapts to novel hosts will therefore provide insight into how a generalist virus with an already broad host range evolves, how fitness tradeoffs between hosts limit simultaneous adaptation to multiple hosts, and whether selection can resolve these fitness tradeoffs over time, leading to further host range expansion. through this project, the researchers will develop new phylodynamic birth-death models for studying adaptive evolution. these methods will be used to estimate the transmission fitness of pathogens in different environments and can even reveal how particular mutations influence fitness. along with developing these methods, the researchers will conduct an extensive field survey of tswv genomic **\*\*diversity\*\***

across multiple hosts to determine the fitness of individual viral genotypes on a panel of crops and native plant hosts. by combining the newly developed phylodynamic methods with empirical measures of viral fitness on different hosts, the researchers will then be able to explore how fitness tradeoffs shape the host range of a generalist viral pathogen and how these fitness tradeoffs evolve over time. viral isolates will also be further experimentally passaged between alternate hosts in the lab to explore how selection can breakdown or resolve fitness tradeoffs between alternate hosts. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Attracting the Next Generation Cybersecurity Workforce

Awardee: Massachusetts Bay Community College

Amount: \$598,712.00

Abstract: this project will address the well-documented need for skilled cybersecurity technicians in the metrowest and greater boston regions of massachusetts. moreover, the project team aims to increase the racial and gender **\*\*diversity\*\*** of the overall cybersecurity workforce that will satisfy those local workforce demands. a replicable and sustainable educational ecosystem will be developed that will recruit, retain, and graduate students in the cybersecurity program at massbay community college. through collaborations with regional industry and high school partners, the program will encourage high school students to pursue degrees, and careers, in cybersecurity. retention efforts will ensure that students majoring in cybersecurity achieve a mastery of the knowledge and the practical skills needed to meet industry expectations. students will be provided with mentoring, career advice and support, and internship opportunities to ensure their success and entry into the cybersecurity workforce. the educational experience provided by massbay will be based on the development of a "cyber range," which is an internet-based computer network platform that provides students with hands-on experience in cybersecurity. exercises will be developed to

give high school and college students practical experiences in cybersecurity. these exercises will be developed in collaboration with industry partners, using their security products, to provide students with real-world experiences in cybersecurity. the project's cyber range will be used to create workshop activities for high school students, develop training materials to instruct and educate students to become peer-mentors, and offer train-the trainer workshops to high school teachers and massbay faculty. high schools, youth serving organizations, and industry partners will use the cyber range to host cyber competitions, hackathons, mentoring, and internships to make students aware of and motivate them to pursue degrees in cybersecurity. this project is funded by the advanced technological education program that focuses on the education of technicians for the advanced-technology fields that drive the nation's economy. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: HSI Implementation & Evaluation Project: Alverno College STEM Community Impact Program (SCIP)

Awardee: Alverno College

Amount: \$598,322.00

Abstract: with support from the improving undergraduate stem education: hispanic-serving institutions (hsi program), this track 2: iep aims to increase retention and graduation of stem majors through focused community engagement activities to enhance stem identity. as a women's college serving primarily first-generation, low-income students, more than half women of color, alverno college will use this project to broaden participation of underrepresented minorities and women in stem, who lag in stem degree attainment and stem workforce participation. increasing racial/ethnic and gender **\*\*diversity\*\*** in stem is a recognized strategy to expand the stem workforce. this project utilizes evidence that women and underserved students in stem are motivated by directly

experiencing the ways that stem benefits their communities. the project will directly engage 400 students enrolled in stem courses, including approximately 125 stem majors, in activities that connect supportive communities to stem curricular and co-curricular experiences. the project engages all stem majors in introductory and capstone community-service activities. it extends peer mentoring to all stem majors and raises the profile of community engagement. the project engages our external community in a cooperative relationship, recognizing the intersection between stem and students' social/community identities. the project will leverage the importance of family support to students of color and women in college success, choice of major and career. a professional mentorship network between current stem students and alumni will capitalize on evidence that professional latinx/ hispanic role models influence stem success. ongoing faculty development in culturally responsive teaching and a formalized administrative support structure will expand project impact across the college.

alverno's project will advance knowledge by investigating the impact of a community engagement program on stem identity, improving retention and graduation into stem careers. the program will measure the association between level of engagement in project activities and college retention, and will analyze participant reflections to understand stem identity development. this work will identify which aspects of the program had the greatest impact on decisions to enter and remain in stem and to pursue stem-related careers. it is anticipated that 100% of stem majors will participate in community engagement activities and that graduates will develop realistic expectations of stem which is critical in meeting community needs. alverno's project will provide a scalable, replicable model for other hsis to adapt. the hsi program aims to enhance undergraduate stem education, broaden participation in stem, and build capacity at hsis. achieving these aims, given the diverse nature and context of the hsis, requires innovative approaches that incentivize institutional and community transformation and promote fundamental research (i) on engaged student learning, (ii) about what it takes to diversify and increase participation in stem effectively, and (iii) that improves our understanding of how to build institutional capacity at hsis. projects supported by the hsi program will also draw from these approaches to generate new

knowledge on how to achieve these aims. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: CAREER: Studies of Chalcogen Bonding-Mediated Assembly towards Porous Crystalline Frameworks, Hierarchical Assemblies, and Multicomponent Materials

Awardee: Colorado School of Mines

Amount: \$597,586.00

Abstract: this award is funded in whole or in part under the american rescue plan act of 2021 (public law 117-2). non-technical abstract: discoveries of new materials have led to seismic advances in our societies. these advances typically occur through breakthroughs with one of two key components of materials: the repeating individual molecular or atomic building block or the way individual components are connected. such materials can be considered analogous to a brick wall, with the bricks as the repeating blocks, and the mortar connecting them together. while an enormous **\*\*diversity\*\*** of building blocks is known, only a handful of established modes of connectivity exist. generally, each different mode of connectivity allows the creation of an entire new class of materials. perhaps the best example for this is the field of nanoporous frameworks, which are sponge-like materials containing voids slightly larger than individual molecules. nanoporous frameworks containing similar bricks, but connected through different mortars, show vastly different behaviors, each type exhibiting a unique combination of properties. with support from the solid state and materials chemistry program in the division of materials research, the principal investigator and their research group develop a new class of nanoporous frameworks enabled by a recently discovered mode of connectivity. in doing so, the principal investigator advances our knowledge of connectivity in materials, particularly by advancing the understanding of this nascent connectivity, realizing unparalleled structural complexities in materials, and developing a class of materials with a

hitherto unseen set of properties. to help teach the core concepts of how building blocks assemble into materials, the investigators also develop and disseminate an inexpensive and highly modular model kit exercise. this level-adaptable game uses multi-colored modeling clay and toothpicks to teach students how the bricks and mortar work together to form materials. to reduce inequalities in upper-division chemistry offerings between research universities and urm-serving primarily undergraduate institutions (puis), the principal investigator develops and offers a hybrid upper-division physical organic course that is simultaneously taught face-to-face at colorado school of mines and remotely to students at institutions across colorado. technical abstract: the manner of bonding between constituent atoms or molecules invariably influences the properties of materials. perhaps no material family is more emblematic of this than synthetic porous frameworks, wherein the properties, and thus utility, of a given subclass rely heavily on the directionality, dynamic reversibility, and net strength of the intermolecular interactions used. therefore, the discovery and characterization of alternative modes of intermolecular assembly that may give rise to complementary material classes are of great interest. the primary objective of this project is to explore if chalcogen bonding, a recently defined non-covalent interaction, can deliberately and reliably assemble molecular tectons into low-density crystalline framework materials, towards the realization of a new class of frameworks: chalcogen-bonded organic frameworks, i.e. chofs. empirical and computational studies of chalcogen bond-mediated assembly in model systems establish a set of quantitative guidelines for the rational design of permanently porous chofs with topologies predictively assembled from the molecular tecton structure and crystallization conditions. these insights lead to compositionally hierarchical and ordered multi-component materials, elusive features in established framework classes. solution-phase association studies, such as nmr spectroscopy and itc, and dft-based calculations are used to quantify chalcogen bonding between synthesized tectons; the atomic structure of assembled frameworks is characterized by single-crystal xrd. an inexpensive and highly modular model kit exercise using modeling clay and toothpicks is developed and disseminated to students with the intent to teach core concepts of

molecular assembly and crystal engineering. to reduce inequalities in upper-division chemistry offerings between research universities and urm-serving puis, the principal investigator develops and offers a hybrid upper-division physical organic course that is simultaneously taught face-to-face at colorado school of mines and remotely to students at institutions across colorado. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Cell biology of cnidarian-dinoflagellate symbiosis: Signaling, regulation and host response pathways

Awardee: Oregon State University

Amount: \$597,545.00

Abstract: coral reef ecosystems are bio\*\*diversity\*\* hotbeds that provide valuable environmental and economic services to half a billion people globally, including millions in the us. reefs are faced with almost complete destruction by the end of the century due to global warming unless humanity can cap global temperature rise. coral biologists are working together to develop a broad array of solutions to help with the coral reef crisis. as a part of these efforts, discovery has a critical role to play. corals are an intimate symbiosis between the coral animal and millions of single-celled algae that reside inside of coral cells. the algae provide photosynthetically derived sugars to the host in return for nutrients and a habitat. dysfunction of the symbiosis, caused by global warming and other human-caused impacts, is the driver of coral bleaching and is causing widespread reef degradation globally. this award will examine the cellular and molecular mechanisms governing the coral-algal partnership. the researchers will use state-of-the-art cellular and molecular tools to discover the

chemical signals exchanged between the partners. they will describe the role of the algae in early development of the host and explore the mechanisms of inter-partner regulation during healthy symbiosis and bleaching. the award includes extensive education and outreach aims. undergraduate, graduate student and postdoctoral fellow training is central to the work. finally, the researchers will engage directly with the public, both in oregon and florida, through a variety of activities aimed at illustrating the importance of corals to science and society. many cnidarians, including corals and anemones, engage in a symbiosis with photosynthetic dinoflagellates (family symbiodiniaceae) that together form the trophic and structural foundation of the coral reef ecosystem. despite the importance of corals to coral reefs and the threatened state of coral reef health in an era of climate change, we have an incomplete understanding of how the partnerships are established, regulated and maintained. the researchers will examine inter-partner signaling and regulation during onset, maintenance and breakdown of cnidarian-dinoflagellate symbioses. experiments will be conducted largely in a laboratory-based sea anemone-symbiodiniaceae model system. the team will carry out the following specific aims: aim 1: characterize algal-host signaling dynamics during onset, maintenance and breakdown of symbiosis by molecular glycan profiling of different symbiont species and by using a unbiased dna aptamer technique to identify surface determinants of symbiotic algae. aim 2: describe the spatio-temporal patterning of symbionts in hosts and their impact on host development and growth by examining the role of symbiosis on polyp development and exploring the dynamics of symbiont invasion in developing polyps. aim 3: examine the role of host response pathways in regulation of symbiosis by measuring changes in nadph oxidase activity and sphingosine rheostat signaling in host tissues both during onset of symbiosis and in dysbiosis. the researchers will develop a course-based undergraduate research experience (cure) based on the sea anemone-symbiodiniaceae model system and they will examine the effectiveness of the cure in student learning and in building of science identity. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Statistical tools for learning about trait evolution across species

Awardee: Florida Atlantic University

Amount: \$596,571.00

Abstract: research on evolutionary biology has been centered on understanding trait variation across species and its contribution to the extraordinary bio\*\*diversity\*\* observed on earth. however, this venture is complicated by a deficiency in computational tools that can effectively navigate evolutionary relationships among species or incorporate large and diverse trait datasets generated

by modern experimental studies. hence, the objective of this project is to expand existing toolkit through the design of a suite of novel statistical and machine learning methods for studying trait evolution across species. these tools will be thoroughly tested through computer simulations, compared to alternative state-of-the-art approaches, and applied to publicly available datasets to address specific evolutionary problems. all tools and datasets generated by the project will be freely and widely disseminated to the scientific community, providing researchers with a powerful framework in which to answer a variety of exciting questions about trait evolution across the tree of life. the project will also advance the participation of underrepresented groups in science and engineering through recruitment of female hispanic high school and undergraduate students to the research team. additionally, the project leaders will design and teach hands-on courses in evolutionary genomics and bioinformatics for retired senior citizens in the local community and for native american communities across the country.

elucidating the processes underlying trait variation across species is a fundamental problem in evolutionary biology, and one for which existing tools lag far behind modern datasets. the current project will address this issue through the design of statistical and supervised machine learning approaches for robustly and accurately predicting the general and specific evolutionary mechanisms by which traits evolve across species. in particular, the tools developed will properly account for species phylogenetic relationships, integrate diverse omics and other trait data, and create new avenues for testing specialized evolutionary hypotheses. availability of these methods will facilitate studies of associations between traits related by a phylogeny, processes and forces driving the evolution of such traits, and adaptive trait evolution arising from different types of structural variations. moreover, findings from applications of these tools to empirical datasets will illuminate connections across different levels of biological organization and diverse biological systems. finally, the developed tools will be applicable to a wide range of ever-increasing genomic, transcriptomic, and other modern omics and trait data, promoting future research in the processes shaping the distribution of traits across species and their roles in evolutionary innovation. results from the project will be available at

<http://assisgroup.fau.edu/>. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: CAREER: Data-Driven Inversion of Subduction Zone Topography using Tectonic Geomorphology

Awardee: Colorado State University

Amount: \$595,128.00

Abstract: the development of earth's topography impacts the flux and routing of surface water, sediment, and nutrients to oceans, affects feedbacks between the solid earth and atmosphere, and impacts the evolution and **\*\*diversity\*\*** of species. earth's topography is also a primary observable of tectonic activity. for example, nearly every earth science student learns to identify deep ocean trenches and adjacent mountain belts as the surface expression of active subduction, where one

tectonic plate dives beneath another. it follows that we should, in principle, be able to use subduction zone topography (or that of any other active orogen) to understand the underlying geodynamic processes involved in its construction. while scientists have made great strides in this direction, recovering tectonic signals directly from topography remains a crucial challenge. this research will develop and apply new methods to narrow this knowledge gap through a case study of the calabrian subduction zone in southern italy. this study will clarify the role of topography as a recorder of subduction zone dynamics and improve understanding of the landscape response to geodynamic forcing by disentangling crustal, mantle, and earth surface contributions to topographic change. the new methods and results will be relevant for better understanding the context of earthquake hazards along these dynamic plate boundaries. through a three-pronged educational outreach program, this project will engage traditionally underrepresented groups in primary research, develop community education modules, and host workshops to train professionals to use the scientific and educational materials developed. this study will conduct a plate boundary-scale paleo-geodetic experiment realized through the development and application of a novel data-driven bayesian inversion of tectonic geomorphology measurements and fluvial topography. this approach will be used to test the hypothesis that the recent and rapid rise of topography above the calabrian subduction zone is driven by mantle dynamics associated with slab tearing and asthenospheric flow around torn slab edges. this study will compile existing and generate new datasets on long-term erosion rates, the magnitude and age of uplifted marine and river terraces, and fault slip and kinematics. this project will train two ph.d. students and three undergraduates through participation in field and lab work, data analysis, modeling, outreach, writing, and national conferences. the integrated education plan will focus on three related components: (1) an undergraduate training network (utn), (2) development of community educational resources, and (3) targeted outreach and training. the utn will recruit three undergraduate students, emphasizing those from underrepresented groups, to participate in a multi-year program to foster the development of next-generation leaders in earth science through participation in research and outreach. working with experts at the geodesy

tools for societal issues (getsi) program and science education research center (serc), community educational resources developed will focus on field geodesy and tectonic geomorphology techniques and datasets generated during this study. outreach and training of the generated scientific and educational materials will be bolstered through participation in getsi-sponsored outreach and the hosting of workshops at national conferences. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: CAREER: Understanding the conservation and restoration potential of retired agricultural land:  
An ecoinformatics approach

Awardee: University of California-Santa Barbara

Amount: \$593,418.00

Abstract: the conversion of land both to and away from agriculture is a central component of global environmental change, with implications for both people and natural systems worldwide. in developed countries including the us, land area in agricultural production is contracting leaving millions of hectares of former or "retired" agricultural land often nested in a mosaic of productive and semi-natural lands. it remains unclear whether, where, and when retired agricultural lands are beneficial to bio\*\*diversity\*\* and ecosystem services in these landscapes. given the ubiquity of agricultural landscapes and the dramatic bio\*\*diversity\*\* declines therein, such a gap is crucial to fill. using a combination of data-driven methods, this research will advance understanding of the drivers of revegetation and the potential conservation value of retired agricultural lands, which can help policy-makers and scientists manage these lands for the well-being of human and natural communities. the training component of this career award will include curriculum development and workshops on the application of data-driven techniques to ecological and environmental problems targeted at high school through phd students. this research will leverage remote sensing, causal

inference, and connectivity modeling methods applied to intensively managed agricultural landscapes to 1) elucidate the mechanisms governing revegetation and succession on retired agricultural lands, 2) understand how the spatial distribution of retired lands influences landscape fragmentation and connectivity, and 3) test whether retired land functions as a net source or sink of crop pests. the education component will engage local high school and first year undergraduates in hands-on research and training in spatial ecology and data-driven environmental science, and train professional master's and phd students in managing, processing and analyzing large spatial datasets and data products to address tractable but complex agricultural ecology questions. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Awardee: University of California-Santa Barbara

Amount: \$593,418.00

Abstract: the conversion of land both to and away from agriculture is a central component of global environmental change, with implications for both people and natural systems worldwide. in developed countries including the us, land area in agricultural production is contracting leaving millions of hectares of former or "retired" agricultural land often nested in a mosaic of productive and semi-natural lands. it remains unclear whether, where, and when retired agricultural lands are beneficial to bio\*\*diversity\*\* and ecosystem services in these landscapes. given the ubiquity of agricultural landscapes and the dramatic bio\*\*diversity\*\* declines therein, such a gap is crucial to fill. using a combination of data-driven methods, this research will advance understanding of the drivers of revegetation and the potential conservation value of retired agricultural lands, which can help policy-makers and scientists manage these lands for the well-being of human and natural

communities. the training component of this career award will include curriculum development and workshops on the application of data-driven techniques to ecological and environmental problems targeted at high school through phd students. this research will leverage remote sensing, causal inference, and connectivity modeling methods applied to intensively managed agricultural landscapes to 1) elucidate the mechanisms governing revegetation and succession on retired agricultural lands, 2) understand how the spatial distribution of retired lands influences landscape fragmentation and connectivity, and 3) test whether retired land functions as a net source or sink of crop pests. the education component will engage local high school and first year undergraduates in hands-on research and training in spatial ecology and data-driven environmental science, and train professional master's and phd students in managing, processing and analyzing large spatial datasets and data products to address tractable but complex agricultural ecology questions. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: CAREER: Dynamics of Fragile Interfaces

Awardee: University of California-Santa Barbara

Amount: \$593,000.00

Abstract: this faculty early career development (career) grant will develop bio-inspired models and experimental approaches for soft materials used in biomedical devices, such as silicone implants, that in operation require the outer surface of the device to slide against living cells and tissues. some current designs may induce inflammation by unintentionally increasing friction, with some aggressively-textured soft implants linked to cases of chronic inflammation and even cancers. this project investigates the dynamics of soft material interfaces guided by the hypothesis that sliding surfaces in nature reduce friction through a delicate balance of fracturing and rapidly re-healing crosslinks between macromolecules in aqueous solutions. this work will develop

biomedically-relevant material systems of different polymer network density and structure, with the long-term goal of creating low-friction interfaces for soft biomedical devices. this project will train undergraduate and graduate students in interdisciplinary research across biology, engineering, mechanics, and physics. these research efforts will be strengthened by engaging students from underrepresented groups through high school outreach activities, including hands-on demonstrations and workshops for local science teachers, undergraduate research opportunities in partnership with minority-serving institutions, and **diversity**-focused scientific seminars for graduate students and postdoctoral scholars. these research efforts address a gap in knowledge and understanding of lubricity in soft aqueous gels and biotribology using engineering tools with molecular specificity, materials characterization techniques, and custom-built instrumentation. the specific research objectives are: (1) develop new models of aqueous gel networks that fracture whilst retaining low shear, (2) synthesize new materials and surface architectures based on hydrogels and weak, self-healing crosslinks to test these hypotheses with in situ experiments, and (3) develop reliable, responsive, and resilient biotribological interfaces for multifunctional purposes and (4) design responsible biodegradable materials by exploring degradation properties and behavior for sustainability purposes. establishing and demonstrating the utility of fragile interfaces to provide robust protection and lubricity will extend the study of the mechano-dynamics of fragile interfaces into new fields from biology to chemistry, and medicine using solid mechanics tools. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: RET Site: Inquiry Driven Engineering Activities using Bioengineering Examples (IDEA-BioE)

Awardee: University of Kansas Center for Research Inc

Amount: \$586,645.00

Abstract: the ret site idea-bioe at the university of kansas will provide middle school mathematics and science teachers an opportunity to participate in research focused on bioengineering at ku. it will also provide guidance on how to translate this experience into engineering design modules that enable teachers to reach and motivate girls and students from minority groups to consider engineering as a career choice. the project will develop long-term relationships with the middle school community of the district to create a "pipeline" for more diverse engineering students in the future, through working with teachers in this targeted school district with a very high percentage of minorities and economically disadvantaged students. the ret site will also integrate educational psychology constructs, to reach a diverse demographic. the effort will have a significant impact on the \*\*diversity\*\* of the engineering student body in kansas, a midwestern state that typically has had very low representation from minority communities in engineering. partnering with the pre-service teaching candidates in ku's stemteachku program will also allow the project to reach beginning science and mathematics teachers early in their careers. dissemination efforts will be focused on publishing lesson modules, and translating modules and evaluation into research articles and case studies in various engineering education and educational psychology journals. dissemination will also be possible via a virtual learning network (vln). next generation science standards (ngss) emphasize the incorporation of engineering design principles and practices into the pre-college curriculum. however, interest in engineering among pre-college students, especially among students from racial and ethnic minority groups, is often low (relative to other stem fields such as medicine), in part due to students' lack of understanding as to the nature of engineering. the ret site will

present a group of 36 pre-service and in-service middle school science teachers with research opportunities that connect complex principles in engineering design (ed) with phenomena and applications from everyday life, in order to engage middle school students with engineering principles while also designing curricular modules with **\*\*diversity\*\*** and inclusion in mind. engineering faculty will provide research experience in various biomedical problems. through partnerships with researchers and educators in the school of education and human sciences, idea-bioe ret participants will also gain knowledge on how their ed modules and lesson plans can be designed to address issues of **\*\*diversity\*\*** and inclusion. final ed modules will also focus on including the promotion of self-efficacy, the provision of relevant models (i.e., women in engineering from a variety of racial/ethnic backgrounds), and incorporation of messages relevant to occupational values. recent research also shows that teachers need additional support and professional development opportunities in order to integrate engineering design practices into their classes, particularly those practices that bridge traditional domains. therefore, this ret site also focuses on presenting bioengineering as an independent discipline which will showcase rationale design and implementation while also highlighting innovation, patenting, and engineering economics, topics which are more specific to engineering disciplines. this project is jointly funded by the division of engineering education and centers (directorate for engineering), and the established program to stimulate competitive research (epscor). this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: IntBIO Collaborative Research: An integrative approach for projecting insect responses to a rapidly changing climate

Awardee: University of California-Davis

Amount: \$582,412.00

Abstract: projecting species' responses to climate change at continental scales is a current 'grand challenge' of ecological research. insects are sensitive indicators of both climate and land-use change and recent studies indicate widespread declines in many geographic regions. to predict changes across entire ranges, a variety of species distribution models have been developed, but rarely account for regional variability, ecological interactions or a species' potential to adapt to changing conditions. this project spans multiple institutions situated in the united states' southwest, polar north, and temperate eastern regions. a series of physiological experiments will be

implemented for five widespread butterfly species with populations sourced from different biomes within each of their ranges. caterpillars will be subjected to a range of conditions mimicking past, current and future climates. their development rate, survivorship, immune response, and genetic structure and gene expression (which genes are actively coding for proteins) will be measured and used to build models that predict distributional shifts. data collected by community (?citizen?) scientists will be used to validate the models. this project requires substantial cross-disciplinary collaboration, and a central goal is to recruit diverse trainees at the graduate and undergraduate levels and train them in the ?science of team science?. project trainees will develop independent research ideas that align with and expand the project?s scope and travel between and work at collaborating institutions as an inter-lab exchange to learn new techniques and be exposed to different research philosophies. finally, the project has significant management implications for insect bio\*\*diversity\*\* conservation. projecting responses to climate change at continent scales is a current ?grand challenge? of ecological research. insects are the most diverse and ecologically important terrestrial animal taxon and are strongly affected by climate change. to predict changes, species distribution models (sdms) have been widely implemented across many taxa. sdms, however, rarely account for ecological interactions, plasticity or evolutionary adaptive potential owing to the extensive physiological and ecological data required to parameterize such models. the biology of lepidoptera, particularly butterflies, is extremely well observed, thus it is logistically feasible to build upon past knowledge and collect additional data that enables mechanisms to be more seamlessly integrated into sdms. multiple populations for each species will be sourced from different biomes across its range. caterpillars will be reared in common gardens under a range of temperature conditions mimicking past, current and future climates. their development rate, survivorship, immune response, genetic structure and gene expression will be measured and used to build models that predict future distributions. distribution data collected by community (?citizen?) scientists will be used to validate and improve models and allow robust estimates of uncertainty. this award reflects nsf's statutory mission and has been deemed worthy of support through

evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Expanding Precision Agriculture Education and Certification to Secondary Students

Awardee: Parkland College

Amount: \$581,377.00

Abstract: with this award, parkland college intends to build on the success of two prior nsf projects in precision agriculture and unmanned aircraft systems to develop a pathway for secondary students to earn a college credential while gaining industry experience. in coordination with industry leaders, community partners, and secondary education organizations, the project will create apprenticeship opportunities and stackable certificates to prepare secondary students for jobs in precision agriculture and adjacent sectors. the stackable certificates will combine coursework in precision agriculture and unmanned aircraft systems and be designed specifically for high school students. participants will complete this curriculum while obtaining industry experience through apprenticeships with industry partners. the project will focus on increasing the **\*\*diversity\*\*** of the agriculture workforce by increasing involvement of female and minority secondary students. food security and agricultural exports are a major part of the us economy. thus, improving training opportunities in agriculture is essential to continuing the strong presence of us agriculture on the world stage. the goals of the project are to establish a new early college and career academy program; establish work-based learning opportunities with regional employers; and increase participation of traditionally underrepresented students in agriculture. the precision agriculture sector continues to modernize and the importance of well-trained students is becoming increasingly critical. many precision agriculture companies struggle to fill open positions as the workforce ages out and the younger generation is drawn away from careers in agriculture. creating new pathways to encourage secondary students to explore careers as technicians in precision agriculture will ensure the availability of a robust workforce. project participants will be well prepared to enter and advance

in the growing precision agriculture industry. by developing credentials and apprenticeship opportunities for secondary students the project will be educating future technicians in line with industry needs. furthermore, the project's focus on increasing the number of women and minorities in precision agriculture will strengthen and diversify an important american industry. the deliverables and best practices developed through the project will be disseminated through coordination with multiple industry partners and a statewide secondary education organization. additionally, the pi and co-pi will attend and present at conferences relevant to agriculture education, agribusiness, and unmanned aircraft systems conferences throughout the grant period. this project is funded by the advanced technological education program that focuses on the education of technicians for the advanced-technology fields that drive the nation's economy. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: RCN: Patterns, Places, People: A Network for Scalable Airborne Observation of Socio-Environmental Systems

Awardee: University of Maryland Center for Environmental Sciences

Amount: \$579,974.00

Abstract: addressing many of the challenges society faces, including climate change, food and water insecurity, and bio\*\*diversity\*\* loss, requires a better understanding of the interactions between people and their environment. important interactions depend on scale (e.g., individuals, communities, government) and environmental conditions, suggesting the value in a landscape perspective. landscapes include people with diverse perspectives and experiences, and there are many different fields of research relevant to understanding how humans and their non-human counterparts interact with changing environments. for this reason, the study of socio-environmental systems (ses) can benefit from transdisciplinary cooperation that engages stakeholders in the

development of scientific research that recognizes and leverages the social and behavioral dynamics of ecological systems. this research coordination network (rcn) project will develop the landscape exchange network for socio-environmental systems research (lens), which will leverage detailed observations from the national ecological observatory network's airborne observation platform (neon aop) to study ses across the united states. lens will build a network of researchers and stakeholders with interest in the neon sites currently observed by the aop. lens will collaboratively work to understand the variability in ses across neon sites and to address environmental outcomes of societal concern to lens membership. broader impacts of this project will include training a graduate student and engaging approximately 1 million people that live within or in close proximity to neon aop landscapes. addressing privacy and ethical concerns, issues of environmental justice, and other concerns of large- and small-holder land-owners and -managers within these landscapes will be central to the work of the rcn. to improve capacity for ses research, societal understanding of ses, and environmental outcomes, this project will initiate and coordinate an rcn for socio-environmental systems research. lens will (objective #1) characterize ses represented in the landscapes surveyed by the neon aop. as these ses are characterized, and in collaboration with neon domain managers, lens will identify and engage stakeholders in network activities from aop landscapes. with scientist and stakeholder members, lens will (objective #2) develop strategies that support an effective translational ecology approach in these landscapes. in doing so, lens will (objective #3) develop and communicate methods for using aop data in ses research using the translational ecology approach. these objectives will be met through a combination of virtual and in-person meetings, data discovery and sharing, development of an online repository of aop-related computational tools, and production of communication products. the network will create and openly share an accessible, curated and transdisciplinary repository of data relevant to ses in the aop landscapes, and will strengthen inter-institutional pathways for translational ecology employing aop. these broader impacts will be a new model for engagement of the public in scientific research. this project is being jointly funded by the macrosystems biology &

neon-enabled science and the human-environment & geographical sciences programs. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Seismological Investigations of Earthquakes and Deep Earth Structure

Awardee: University of California-San Diego Scripps Inst of Oceanography

Amount: \$579,568.00

Abstract: this project will use decades of records of seismic waves generated by thousands of

earthquakes all over the world to learn about both earthquakes and deep earth structure. analyses of earthquakes will focus on the high-frequency components of the seismograms, which provide key constraints on the energy radiated by earthquakes and information about the speed and complexity of fault ruptures. these results should help improve forecasts of damaging ground motions produced by strong earthquakes. planned analyses for earth structure will examine sharp changes in seismic wave velocities that occur at depths of 50 to 400 miles below the surface that are related to changes in crystal structure or the presence of fluids, such as water or magma. a related project will examine scattering of seismic waves, which provides clues regarding small-scale variability in rock properties at depths extending from the surface to earth's liquid core. these results will help in understanding the internal composition of the earth and its relation to tectonic processes. the project will support undergraduate, graduate, and postgraduate students and involve them in research. educational components include graduate student and postdoc support, as well as sponsoring an undergraduate summer intern in a long-standing and successful sio program designed to increase student **\*\*diversity\*\***. systematic analyses of large datasets recorded by both permanent and temporary seismic stations all over the world provide rich opportunities to study problems concerning earthquakes and earth structure. planned research includes innovative investigations of upper-mantle discontinuity structure within and near the transition zone and the lithosphere-asthenosphere boundary, observing and modeling of seismic scattering to characterize small-scale compositional heterogeneity in the mantle, and spectral analyses of earthquake radiation to constrain earthquake rupture dimensions and dynamics. some key questions this project plans to examine include: (1) what is the role of the low-velocity layer (l<sub>v</sub>) above the 410-km discontinuity in mantle convection and water recycling? (2) what causes the mid-lithospheric discontinuity (mld) observed under many continental cratons? (3) how variable is the sharpness and roughness of the 660-km discontinuity and what does that imply for mantle composition? (4) what is the strength of small-scale heterogeneity in the mid- to lower mantle and does it vary laterally? (5) what causes the large scatter in earthquake stress drop estimates, i.e., how much is

due to modeling uncertainties versus real differences in earthquake dynamics? (6) does earthquake stress drop vary systematically with tectonic region? (7) how do improved global high-frequency body-wave attenuation models compare to tomographic models and to surface-wave attenuation models? this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: IUCRC Proposal Phase I: University of Colorado Boulder: Center for Building Energy Smart Technologies (BEST)

Awardee: University of Colorado at Boulder

Amount: \$578,500.00

Abstract: the building energy smart technologies (best) iucrc brings together universities and industries to transform the building industry through the development and adoption of sustainable and intelligent technologies. best will apply innovative, energy-smart technologies through a wide spectrum of us buildings. best will be located in two sites: the lead site at university of colorado boulder (cub) and the partner site at city college of new york (ccny), taking advantage of the diverse academic, natural and industrial environments these locations provide. the best center will foster smart, sustainable, and efficient development and utilization of energy in the built environment through an integrated systems approach to design, retrofit, construct, and operate sustainable buildings and cities. ultimately, the best center will support the u.s. building industry's efforts to meet increasingly stringent building energy-efficiency regulations, and society's expectations for improved sustainability, resiliency, and security in communities and cities. the best center will

support the goal of achieving net-zero greenhouse gas emissions by 2050. moreover, the center will educate and train a skilled and diverse workforce to address current and future employment needs for the u.s. building industry. the best center will enable the development of new and sustainable building energy technologies through a holistic understanding of the interactions between built and-natural systems. in particular, the center will address design and operation solutions for the built environment associated with extreme weather events, which are becoming more frequent and intense due to a rapidly changing climate. additionally, the center will focus on the emerging challenges in the building sector due to pandemics and health crises such as those caused by covid-19, and increase cybersecurity of the buildings systems and of occupants? privacy. the center?s research scope spans various disciplines specific to building energy systems, including indoor-outdoor energy flows, advanced building envelope systems, demand-response informatics, application of advanced in-situ and remote sensing for monitoring the environment and occupants, and distributed energy efficient and renewable technologies. to cover the rich and wide \*\*diversity\*\* of the building industry needs, five thrust areas are proposed for the center?s research activities: (i) smart buildings materials, (ii) intelligent building mechanical and electrical energy systems, (iii) distributed and renewable energy systems, (iv) city-scale building energy systems and informatics, and (v) smart grid systems integrated with distributed energy and data systems. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Sustaining Arctos as a Community of Practice and as a Collection Management Solution for Biodiversity Research & Education

Awardee: University of New Mexico

Amount: \$574,694.00

Abstract: an award is made to three partner institutions ? the museum of vertebrate zoology (univ.

california berkeley), museum of southwestern biology (univ. new mexico albuquerque), and the texas advanced computer center (univ. texas austin) ? to perform critical technical and infrastructure work that will establish a sustainable framework for arctos, a database and collection management system. the arctos community is a group of museum-based professionals representing natural and cultural history collections at over 40 institutions that share in the governance, design, maintenance, and development of arctos. a primary objective of the arctos community is to make high quality data on bio\*\*diversity\*\* and cultural collections openly accessible and richly networked for multidisciplinary research and public understanding. this is accomplished through the arctos online platform, which serves primary species and cultural data to national and international users. these data are used to advance knowledge in a \*\*diversity\*\* of disciplines and serve as an archival record for future generations. additionally, the arctos platform is used as an educational tool where students access raw data to design original inquiries. the arctos community is dedicated to rigorous management of collections and their data, as well as mentoring and training the next generation of curators, collection managers, and scientists. arctos views collections comprehensively and promotes linkages across biological, earth science, art, archival, and ethnographic collections to add value and relevance for education and research. for example, cultural and archival records often contribute temporal, ecological, and behavioral dimensions to bio\*\*diversity\*\* data from identifiable species components or observations. many museums curate more than one type of collection, and arctos provides a comprehensive management solution integrating diverse disciplines. for the last 20 years, arctos has practiced the concept of the ?extended specimen network?. the richly annotated data in arctos creates a web of knowledge with deep comprehensive relationships between cataloged records and all of their derived and associated data, and by using reliable published resources for globally shared information such as taxonomy, people names, and geography. to sustain this community-driven infrastructure and resource, the arctos database platform will complete migration to open-source technologies removing the need for costly software. other benefits include stabilizing web services, query responses and delivery, spatial functionality,

among other core features. the arctos model of community engagement and development is attractive for collections of any size, including small institutions such as field stations that may lack it infrastructure, because of its ease of cloud-based access, community mentorship, and enterprise-level platform at scaled pricing. project activities and results will be accessible on the arctos websites (arctos.database.museum and arctosdb.org). this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: CAREER: Geometric Quantum Order: Fractons, Tensor Gauge Theories and Beyond

Awardee: Brown University

Amount: \$574,588.00

Abstract: nontechnical summary this career award supports joint theoretical research and education to advance the theoretical foundations of condensed matter physics. condensed matter physics concerns itself with systems composed of a large number of interacting constituents. materials are a common example as they contain many atoms and many electrons. it is common to think of such complex systems not in terms of the individual constituents, but rather in terms of properties that emerge from their collective behavior. the concept of phases of matter is an important example of a collective property. systems that show the same phase have similar properties. ferromagnets have the collective property that the constituent atoms or electrons align in such a way that the magnetic axis of each one points in the same direction. ferromagnets made of different materials are all ferromagnets. however, a ferromagnet is qualitatively different from an antiferromagnetic phase in which the magnetic axis of one atom points in the direction opposite that of its neighbor. so, systems that belong to the same phase have similar qualitative properties, while systems that belong to different phases have different properties. when quantum mechanics mingles with strong interactions among constituents very strange phases can emerge, such as the topological phases

of the fractional quantum hall effect; the latter occurs when electrons confined to a two-dimension plane by semiconductors are exposed to an intense magnetic field. recently proposed fracton phases of matter are another turning point in this development. these phases have the interesting and distinct property of being hypersensitive to the geometry of the underlying material, for example the way atoms are organized on a lattice, as well as the presence of geometric distortions of the lattice. the pi will undertake a careful study and characterization of these phases, which necessitates the development new concepts and new theoretical tools. new tools will help advance understanding of the physical properties of fracton phases as well as suggest routes for experimental detection of fractions in materials. this is fundamental research; however, fractons could play an important role in developing quantum memory, and suggest new ways to think about quantum computing. finally, it is already becoming clear that some fracton phenomena may have been discovered long ago in superfluids and liquid crystals, without realizing that these are but a page of a much bigger story. the pi will utilize the new techniques developed in the fracton context to gain new insights into the problems of vortices in superconductors, turbulence, and quantum liquid crystals.

the education component of this career project includes training undergraduate and graduate students. students will explore how to use machine learning methods to gain insight into theoretical problems. the pi will participate in global efforts to increase **\*\*diversity\*\*** in physics through mentoring undergraduate students who are members of underrepresented groups leveraging american physical society initiatives. the pi will engage in outreach in local high schools by participating in career days and encouraging students to study science. pi will develop a course aimed at undergraduate and graduate students that will focus on applications of condensed matter physics ideas to deep neural networks.

technical summary this career award supports joint theoretical research and education to advance the theoretical foundations of strongly correlated topological and geometric phases of matter. the project is focused on the physics of systems that support emergent fracton excitations. these excitations possess two remarkable properties: (i) they are topologically non-trivial and (ii) they cannot freely move through space. the constraints on their

motion arise dynamically, while the underlying physical system is translation invariant. more concretely the research concentrated on three major efforts. (i) fracton excitations can emerge in gapless correlated spin liquids. the pi will explore how the existence of these excitations affects observable properties of these systems. (ii) the constrained mobility of fracton excitations can be formally imposed by introducing additional symmetries. the variety of all possible mobility constraints roughly corresponds to all possible symmetries of this kind. the pi will develop a general theory of such symmetries and their manifestation in low energy properties of the physical systems constrained by these symmetries. (iii) a particular form of fracton behavior is already present in well-known systems such as superfluids, liquid crystals and quantum hall states, where vortices, crystalline defects and composite fermions have a subtle version of constrained motion. the pi will investigate this tantalizing connection with the expectation that fracton machinery will provide a fresh look at these systems. the education component of this career project includes training undergraduate and graduate students. students will explore how to use machine learning methods to gain insight into theoretical problems. the pi will participate in global efforts to increase **\*\*diversity\*\*** in physics through mentoring undergraduate students who are members of underrepresented groups leveraging american physical society initiatives. the pi will engage in outreach in local high schools by participating in career days and encouraging students to study science. pi will develop a course aimed at undergraduate and graduate students that will focus on applications of condensed matter physics ideas to deep neural networks. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Pulmonary Aerodynamic Valves: Distribution & Function

Awardee: University of Utah

Amount: \$566,507.00

Abstract: this project addresses a major, poorly understood question in vertebrate evolution related to the lung's extraordinary structural **diversity**, especially the structures that give rise to one-way airflow. bird lungs have held a special place in this regard, because their design is so radically different from mammalian lungs, and it has been thought that one-way airflow is related to the energetic demands of flight. however, the lungs of other non-flying vertebrate animals, including snakes, turtles, and chameleons, also differ from those of mammals. this research will provide a better understanding of how aerodynamic valves in the lungs of reptiles give rise to one-way airflow, the physiological significance of these patterns of flow, and their distribution across vertebrate animals. it will reveal fundamental, form-function relationships linking lung structures to patterns of airflow in reptiles and amphibians; enhance understanding of the effects of these patterns of airflow on gas exchange, respiratory water loss, and heat loss; and be applied to reconstruction of the respiratory systems of extinct tetrapods. the project also includes significant educational and outreach activities, including science communication training for lab personnel, participation in public-education, distance-learning programs run by utah's hogle zoo, and development of virtual reality infrastructure for research, outreach, and teaching. three primary activities will result from the proposed research. (1) a phyletic survey will be made of patterns of airflow in the lungs of amphibians and reptiles. (2) tests of the following hypotheses for the mechanistic basis of pulmonary aerodynamic valves will be made by measurements and visualizations of patterns of airflow, computational fluid dynamics simulations, and physical models: i) that turtles have a pulmonary tesla valve; ii) that the expiratory valve of archosaurs functions like an internal nozzle, where a coanda surface induces and amplifies flow; iii) that the expiratory valve arises from a caudal guiding dam. (3) balloon catheters will be implanted into the lungs of alligators which will allow unidirectional flow

to be converted to tidal airflow. under these two flow regimes hypotheses for the functional significance of aerodynamic valves will be tested: i) that alligators have counter-current or cross-current gas exchange; ii) that unidirectional flow reduces rates of evaporative water and heat loss, and improves wash-out of lung  $\text{CO}_2$  and wash-in of  $\text{O}_2$ . measurements will be made of  $\text{O}_2$  extraction and  $\text{CO}_2$  removal with each breath, rates of lung washout of  $\text{CO}_2$ , rates of respiratory evaporative water loss and heat loss, and rates of ventilation relative to rates  $\text{O}_2$  consumption and  $\text{CO}_2$  excretion. the proposed research has four strands of educational and outreach broader impacts: 1) recruitment of underrepresented participants into stem; 2) training of lab personnel in science communication, working closely with the natural history museum of utah; 3) outreach to the lay community, including k-12 schools, through distance-learning programs of utah's hogle zoo; 4) development of virtual reality infrastructure for research, outreach, and teaching. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: RCN-UBE: A Network for Facilitating Online Content for Experiential Learning of Tropical Systems

Awardee: Iowa State University

Amount: \$563,619.00

Abstract: life science students must be prepared for solving ?wicked? problems, i.e., complex ones without clear solutions. these problems require higher-level thinking about the connections across scales and disciplines, and within a global context. tropical ecology provides opportunities for studying this kind of complexity, from the interactions of organisms in highly diverse communities to the web of social and economic considerations that guide the processes and conservation of tropical species and ecosystems. despite this, most core undergraduate biology curricula retain a primarily temperate-zone lens and limited exposure to the global **\*\*diversity\*\*** of ecosystems and cultures. at the same time, there is a critical need for online open educational resources (oers) that incorporate real-world examples and are easy for both students and instructors to access and use. this network brings together a diverse community of experts with backgrounds in tropical biology research, active-learning pedagogy, software development, and multimedia content creation. the network activities will support faculty participants in the creation and adaptation of field- and research-based oers. these online modules will be hosted on a responsively designed, open-source and open-access platform, gala. the goals of the online content for experiential learning of tropical systems network are to: internationalize the undergraduate biology curriculum through the creation of oers in tropical ecology; enhance and innovate within platforms such as gala to facilitate the integration of quantitative elements within oers; and broaden participation within the biology community by engaging participants from under-represented groups, hbcus and community colleges. activities will include: initial workshops to create author guidelines and toolkits; 'incubator'

workshops to develop new oers; faculty mentoring networks for adapting existing oers; and engagement with professional societies and other networks to expand and sustain this new network. for each module, design and development of interactive and quantitative elements will be undertaken in collaboration with the developers of the gala platform, the midwest big data hub, and quantitative undergraduate biology education and synthesis. as this new network?s agile process for creating oers is refined, it will provide a novel framework for oer development that can help propel stem education in fields beyond tropical ecology. this project is being funded by the directorate for biological sciences, division of biological infrastructure as part of efforts to address the challenges posed in vision and change in undergraduate biology education: a call to action (<http://visionandchange/finalreport/>). this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: CAREER: Multiscale Mechanics of Carbon Nanotube-Polymer Composites

Awardee: Howard University

Amount: \$562,555.00

Abstract: this faculty early career development (career) grant will support research on understanding the fracture mechanisms and predicting the mechanical properties of carbon nanotube-filled polymer composites. these materials have the potential to play a growing role in the prosperity, security, and global competitiveness of the united states and propelling the economic performance of major industrial sectors such as aerospace, manufacturing, biomedical, and civil infrastructure. polymer composites are tunable materials whereby changes to their constituents, processing conditions, and microstructure one can achieve products with distinct functions. understanding the processing-structure-property relations and failure mechanisms of these materials, however, is complicated because they feature a wide range of compositions, phenomena, and interactions across several scales of time, length, complexity, and uncertainty. this research aims to unravel these relations and mechanisms and in turn supplant the traditional trial-and-error approach to the design of polymer composites by an efficient, machine learning-assisted, experiment-informed, multiscale computational approach that will accelerate the discovery of novel polymer composites with improved manufacturability, reliability, and performance, ultimately benefiting the economy and society. the educational and outreach components of this project will contribute to enhancing **\*\*diversity\*\*** in stem multidisciplinary education and include developing courses in advanced materials and forming sustainable collaborations between the pi's research group and industry partners and professional organizations. among the scientific and technological challenges remaining in the field of carbon nanotube-filled polymer composites, one of the least-understood areas is the deformation and failure of these materials and a poor understanding of load transfer in them at the filler-matrix interface. this project will further elucidate the phenomena and mechanisms that underlie the mechanical response of these materials at the nano- and microscales and quantify their processing-structure-property relationships by developing a probabilistic framework comprising laboratory tests, microscopic characterizations, image processing, multiscale modeling and

simulations, and machine learning. the uncertainties involved will be quantified, and a probabilistic multiscale modeling and simulation hierarchy will be developed to study high-fidelity models of polymer composites. machine learning will be used to perform sensitivity analyses and develop probabilistic predictive models for the properties of polymer composites. the study outcome will offer a new route to design heterogeneous, high-performance, and multifunctional composite materials. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: DMREF: Symmetry-Guided Machine Learning for the Discovery of Topological Phononic Materials

Awardee: Massachusetts Institute of Technology

Amount: \$560,000.00

Abstract: non-technical description: fundamental understanding and control of heat conduction processes in materials are important for energy infrastructure, electronic devices, and renewable energy generation systems. this project focuses on a novel property of phonons ? vibrations of

atoms that carry the heat in materials - called "topology". this property may allow new phenomena, such as heat conduction perpendicular to the temperature gradient direction and more efficient transport of heat waves on the material surfaces. to discover topological phonons, the research team will exploit a materials genome approach to search for materials hosting these special heat carriers. once candidates are identified, the research team will synthesize and characterize them, and the results will be used to refine the search algorithm. the research team plans to establish a public database storing the heat conduction properties of a large number of materials. this research will not only advance the fundamental understanding of how topology affects heat conduction in real materials, but also provide new routes to realizing unusual functionalities such as heat conductors that can be switched on and off. this project also supports educational activities to teach basic materials physics concepts to k-12 and undergraduate students through hands-on class projects and short courses. to promote **diversity** in the materials science workforce, the team also provides research opportunities to high school and undergraduate students from underrepresented minority communities.

technical description: while the topology of electronic states has been a central theme in condensed matter physics for the past decade, topological phononic states have received much less attention. unlike their fermionic counterparts, topological states in the entire phonon spectrum can contribute to observable material properties, making topological phononic materials ideal testbeds for emerging new physics in topological bosonic systems, including phonon thermal hall effects, novel topological phonon-electron interactions and the resulting phenomena, such as unusual superconducting states. this project aims to systematically identify materials hosting intrinsic topological phonons in the thermal regime, where the topological phononic states explicitly modify intrinsic material properties, including thermal transport, electron-phonon interactions, and surface phonon modes. the research team will seek to accelerate material discovery by incorporating symmetry-guided machine learning based on euclidean neural networks. machine learning predictions will be verified using first-principles phonon simulation and topological invariance analysis. promising candidate materials will be synthesized as thin films and bulk single

crystals and characterized using inelastic neutron and x-ray scattering, thermal transport, and surface-sensitive spectroscopy and scanning probe measurements. this research will advance fundamental understanding of topological bosonic systems and examine new thermal functionalities enabled by topological phonons. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Ideological Roadblocks to Diversifying STEM: Resistance and Allyship in STEM Diversity and Inclusion Efforts

Awardee: Regents of the University of Michigan - Ann Arbor

Amount: \$559,600.00

Abstract: ideological roadblocks to diversifying stem: resistance and allyship in stem **\*\*diversity\*\*** and inclusion efforts the aim of this project is to break important ground in stem inequality research by better understanding how powerful and privileged groups in stem respond to **\*\*diversity\*\***, equity, and inclusion (dei) efforts in their workplaces and professions. despite the millions of dollars invested each year in dei-related training, recruitment, and retention efforts, stem fields have struggled to diversify demographically and culturally. much research over the last few decades has sought to understand the interactional and institutional-level biases that disadvantage women, people of color, and lgbtq individuals in stem. yet, these biases are not the only ways in which inequality and under-representation are perpetuated. central to stem's stalled diversification are sources of resistance to organizational and institutional changes that seek to advance equity. such resistance can block both the effective implementation of existing dei efforts and the development of new initiatives that would bring deeper structural and cultural transformations. this project seeks to investigate resistance to dei efforts among the population with the greatest structural and cultural power in stem. while many individuals in powerful social groups are personally committed to equity

and inclusion, others may disagree with, and even actively resist, dei efforts in their organizations and professions. the goal of this project is to map the wider landscape of cultural schemas that individuals in powerful social groups use to make sense of dei efforts and to express their resistance to or support for those efforts. using an innovative combination of analysis of existing survey data, interviews with a representative sample of individuals in powerful social groups stem professionals, and a survey experiment, the empirical goals of this project are to (1) investigate resistance to and support for dei efforts relative to their peers, (2) document the roadblock schemas (or shared cultural models) that individuals in powerful social groups may use to frame such resistance to dei efforts, and (3) test interventions that attempt to destabilize adherence to these roadblock schemas and, by extension, resistance to dei efforts. in doing so, this project would offer critical insights to assist academic institutions, workplaces, and professional societies in designing strategies to overcome those roadblocks and promote more effective dei efforts. such an investigation may also contribute to stem inequality, cultural sociology, and sociology of professions literatures by illustrating how cultural norms of professional integrity, which seem on their face to be a degree removed from issues of inclusion or inequality, can serve as powerful tools of resistance to diversification within professions. broadly, understanding the cultural frameworks that powerful social groups use to defend their privilege and resist change is vital for overcoming the stalled diversification of stem and advancing race, gender, and lgbtq equality therein. this project is funded by the ehr core research (ecr) program, which supports work that advances fundamental research on stem learning and learning environments, broadening participation in stem, and stem workforce development. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: AF: Medium: Markov Chain Algorithms for Problems from Computer Science, Statistical Physics and Self-Organizing Particle Systems

Awardee: Arizona State University

Amount: \$551,999.00

Abstract: self-organization can be viewed as a phenomenon whereby unanticipated global configurations and patterns of a collective emerge from fully distributed and simplistic rules performed by each individual, without any global coordination or external intervention.

self-organization and emergent behavior arise naturally across many fields: distributed systems and swarm robotics in computer science, interacting particle systems in physics, population dynamics and flock coordination in biology, autonomous systems in robotics and control theory, and smart materials, to name a few. recently, the synergy between discrete probability, algorithms and statistical physics has provided a new approach for designing self-organizing particle systems by harnessing collective, emergent behavior of physical systems. the laws of physics play an increasingly important role in collective behavior at the nano- and micro-scales, especially since individual agents are far less capable than their macroscopic counterparts. yet, while the principles of statistical physics have motivated many experimental systems, little has been done to make the corresponding underlying distributed algorithms rigorous. this project investigates how to

program collections of agents to perform tasks by modeling the dynamics as self-organizing particle systems performing steps of markov chains through local interactions that can be rigorously analyzed. the limiting distributions of these chains have distinct equilibrium characteristics that can be used to program collective behavior. the principal investigators take a three-pronged approach: first, they introduce and study generalizations of common statistical physics models, such as the potts, ising and hard-core models, to better capture the constraints imposed by micro-scale systems of interacting agents. next, they explore methods to better understand the nonequilibrium dynamics of these systems long before convergence and possibly subject to forces that make the markov chains nonreversible. finally, they explore how collective systems might be programmed through deliberate placement of obstacles and features in the environment, rather than programming the agents themselves, as many of these tiny agents are incapable of any sophisticated (traditional)

computation. as an example of programming the environment, a new version of the schelling segregation model is being studied where people move with higher probabilities if they are unhappy with the local demographics of their neighborhoods, but these preferences can be somewhat mitigated by the placement of desirable urban infrastructures that modify individuals' incentive structures and biases. the project is having impact in promoting and advancing interdisciplinary research across many fields; education, through advanced graduate courses and broad, interdisciplinary talks; **diversity** at the graduate, undergraduate, and faculty levels; outreach to the general public and for k-12 education; and municipal planning, through coordination with regional planning faculty and the city of atlanta. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: i-learn: empowering engineering learners using visualizations in mixed reality and machine learning ecosystems

Awardee: Illinois Institute of Technology

Amount: \$551,436.00

Abstract: in the field of engineering education, significant research on learning with technologies has focused on either the learner's interaction with the technology, on technology-enabled learning material, or on final learning outcomes. research on learning with technologies involving the influence of individual cognitive function (perceptual, attentional, and cognitive skills) is relatively unexplored. there remains a gap in knowledge on how or why learners arrive at different results in the learning process. the i-learn research project bridges that divide by considering the learner's individual characteristics as they execute problem-solving tasks while interacting with the advanced technology-enabled environments ? a machine-learning (ml) and mixed-reality (mx) technology. the i-learn research project's theoretical and empirical methods will provide fundamental knowledge about how learners' cognitive function can be augmented through the advancements of these technologies, closing the gap in understanding the **\*\*diversity\*\*** of individuals' perceptual and cognitive abilities in engineering education. the perspective of tailoring mx with ml technologies to predict individual problem-solving harnesses opportunities to research whether learners' interactions with these technologies leads to improved task performance. i-learn creates mx-based environments with features informed by ml models not merely as interactive features but as a medium of communication for perceptive-action. by focusing on components of learning cognition (e.g., working memory and sustained attention) as well as mental simulation and situational awareness, this project (1) uses ml predictive modelling to explore the effects of individual differences on learners' performance in problem-solving tasks modelling, (2) studies learners' moments of impasse in problem-solving tasks that demand spatial and cognitive ability, and (3)

develops and assesses the effectiveness of an interactive and adaptive mx platform for learning when used by students with different cognitive and attentional abilities. this project will improve the fundamental understanding of how technologies should be designed to enhance technology-enabled learning. it promotes embodied cognition, pioneers individualized learning using ml, and advances insights on the effect of motor activity on operations linked to visuo-spatial abilities. research outcomes will inform the design of adaptive learning technologies and the customization of instruction in engineering education. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: D3SC: Developing Data-Driven, Automated Methodology to Understand and Control Light-Driven Catalytic Processes

Awardee: Carnegie-Mellon University

Amount: \$550,000.00

Abstract: with the support of the chemical catalysis program in the division of chemistry, professor stefan bernhard of carnegie mellon university will study catalytic processes that are driven by light. continued development of a sustainable society requires advances in molecular sciences that will pave the way to the solar-powered, efficient, safe and precise molecular engineering of new functional molecules, materials, and fuels. one of the major obstacles on this path stems from the inherent difficulty of extending current chemical theories to accurately describe the interplay of matter and energy in light-driven chemical transformations. the proposed work utilizes an investigative approach that seeks to accelerate chemical discovery and enhance control of chemical reactions by developing new tools integrating high-throughput experiments, quantum chemistry, and data science. the bernhard lab involves a diverse group of researchers to accomplish these research tasks. stefan bernhard and his research team will be involved in outreach activities for

non-scientists to educate the public on energy issues and instill excitement for science, in general. with the support of the chemical catalysis program in the division of chemistry, professor stefan bernhard of carnegie mellon university will study the complex interplay of reagents and catalysts in light-driven chemical processes. the funded research will create a deeper understanding by using new tools integrating high-throughput experiments, quantum chemistry, and data science. the created artificial intelligence resulting from a merger of chemical theory and chemical data will allow the capture of the effects of complex many-body electronic interactions that elude current algorithms. to gather the data needed to drive this effort, the bernhard team will develop massively parallel, automated chemical reactors capable of sensing and recording the progress on a variety of reaction types in parallel and in real time. increasingly complex photochemical processes ranging from simple energy transfers to light-driven polymerizations will be investigated and their observed reactivity patterns will be modeled, compared and analyzed. the initial phase of the work will focus on photocatalytic reactions catalyzed by iridium complexes. these are expected to provide an excellent trial system due to the ability to easily synthesize structures that span a vast chemical space, but where the structure-activity relationships have been difficult to model and predict. later efforts will increase the chemical and structural **\*\*diversity\*\*** of the photocatalyst by inclusion of a much wider variety of ligand frameworks and involving central ions with a range of electronic structures. quantum chemical calculations on the photocatalysts will be the basis of a feature learning-based approach to find and predict structure property/(re)activity relationships in the studied photochemical systems. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: CAREER: Unlocking Reactivity-Based Separations of Olefins using Metal-Organic Frameworks

Awardee: Cornell University

Amount: \$550,000.00

Abstract: chemical separations, which involve partitioning a mixture of compounds into its individual components, are critical to the industrial production of commodities such as plastics. separations account for 15% of energy consumption in the united states alone. the development of new energy-efficient separations could greatly reduce greenhouse gas emissions, improve the sustainability of the chemical industry, and decrease the cost of everyday consumer products. traditionally, separations are carried out based on differences in the physical properties of chemicals, such as their boiling points. here, the investigator will develop sponge-like materials capable of separating chemicals based on their differing reactivities. this will enable industrial separations with much higher selectivities for one component over another and potentially unlock new types of separations. this project will be highly interdisciplinary, involving aspects of chemistry, chemical engineering, and materials science, which will help strengthen communication between these fields. in addition, new scientists from underrepresented communities will be trained, improving the **\*\*diversity\*\*** of the stem workforce. as part of the project, the public, especially underserved students in rural communities, will learn about the importance of chemical separations, sustainability, and green technologies. unsaturated molecules such as olefins are critical building blocks for the global production of polymers. however, polymerization reactions typically require ultrapure streams of olefins to proceed efficiently. currently, mixtures containing olefins (including mixtures of olefins/paraffins or olefin isomers) are inefficiently separated based on small differences in their physical properties. this project seeks to separate mixtures containing olefins based on differences in their reactivities rather than physical properties. specifically, porous crystalline materials known as metal-organic frameworks (mof) will be designed such that they can undergo reversible cycloaddition reactions with olefins. these novel mof systems will allow for separations to be carried out with unparalleled selectivities and for the production of ultrapure olefin product streams in an energy-efficient manner. the materials design strategy is potentially generalizable to

separations involving a range of unsaturated molecules, including carbon dioxide, reflecting the versatility of this approach. the separation efficiency of the strategy will be assessed using gas adsorption analysis and breakthrough measurements. the reactivity of the adsorbents will be characterized using in situ solid-state nuclear magnetic resonance, x-ray diffraction, and infrared spectroscopy. this interdisciplinary research program will forge new connections between chemists, chemical engineers, and materials scientists. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: CAREER: Elucidating the Interfacial Structure of Complex Solvents for Chemical Transformations

Awardee: Case Western Reserve University

Amount: \$549,957.00

Abstract: the availability of high-performing solvents that function as absorbents, co-catalysts, and electrolytes is a critical and unmet need for advanced technologies such as integrated capture and conversion of carbon dioxide. this project will develop functionalized solvents that have high affinity to carbon dioxide as well as facilitate its efficient conversion to other useful products such as fuels. these complex solvents are hydrogen-bonded organic complex (hboc) liquids with high concentrations of salts and often have molecular-scale structure and heterogeneity. the mechanisms of absorption and reactivity of carbon dioxide at the electrode-electrolyte interface are not well understood in these solvents. this project will explore the fundamental mechanisms that underpin absorption, interfacial liquid structure, and reactivity to inform future designs of integrated systems for chemical transformations. the knowledge gained has far-reaching applications in separations, catalysis, sensors, and other electrochemical processes. through these applications, this research addresses the societal challenges of climate change, emission mitigation, waste utilization, and

energy consumption. the educational goal of this career project is to enhance students' learning experience using visuals and to build science literacy through drawing. visual illustrations of the scientific concepts of this project will be created for use as educational materials, which will be disseminated via publications, seminars, and public events. these activities will foster teamwork and strengthen ties with the local community in cleveland through collaboration with the cleveland institute of art. with support from both the interfacial engineering and electrochemical systems programs, this project will characterize the liquid structure of concentrated electrolytes at interfaces with electrified surfaces and quantitatively assess the structural impact on charge distribution, thermodynamics, and reaction mechanisms in separation processes and electrochemical reactions. the solvation structure and reactive state of the carbon dioxide model compound both within and at h<sub>2</sub>o electrolyte-electrode interfaces will be investigated by spectroscopy, neutron and x-ray reflectivity, and electroanalytical techniques. these studies will provide a basis for understanding the structure and dynamics of the behavior of small molecules in complex solvents. more specifically, the following scientific questions will be answered: (1) what is the physical environment of the carbon dioxide solvate complex at the electrode-electrolyte interface? and (2) what is the impact of the interface structure on electron and proton transfer and selectivity of the carbon dioxide reduction mechanism? the results from this study will contribute to the understanding of electrical double layer structures of h<sub>2</sub>o electrolytes, as they cannot be explained by the traditional models suitable for dilute systems. the results will also impact the discussions on the role of the electrolyte in carbon dioxide co-catalysis. the project will apply the stem educational concept of "learning by drawing" and artistic illustration in undergraduate and graduate-level courses and public outreach. learning by drawing is expected to enhance student engagement in engineering courses, improve visual literacy, promote knowledge retention, increase \*\*diversity\*\* among students pursuing stem-related fields, as well foster interdisciplinary communication between art and engineering students. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: CAREER: Knowledge-Rich Neural Text Comprehension and Reasoning

Awardee: University of Washington

Amount: \$549,843.00

Abstract: enormous amounts of ever-changing knowledge are available online in diverse textual styles (e.g., news vs. science text) and diverse formats (knowledge bases vs. web pages vs. textual documents). this proposal addresses the question of textual comprehension and reasoning given

this **diversity**: how can artificial intelligence (ai) help applications comprehend and combine evidence from variable, evolving sources of textual knowledge to make complex inferences and draw logical conclusions? recent advances in deep learning algorithms, large-scale datasets, and industry-scale computational resources are spurring progress in many natural language processing (nlp) tasks, including question answering. nevertheless, current models lack the ability to answer complex questions that require them to reason intelligently across diverse sources and explain their decisions. further, these models cannot scale up when task-annotated training data are scarce and computational resources are limited. our results will give rise to the next generation of question answering and fact checking algorithms that offer rich natural language comprehension using multi-hop and interpretable reasoning even when annotated training data is scarce. with a focus on textual comprehension and reasoning, this research will integrate capabilities of symbolic ai approaches into current deep learning algorithms. it will devise hybrid, interpretable algorithms that understand and reason about textual knowledge across varied formats and styles, generalize to emerging domains with scarce training data (are robust), and operate efficiently under resource limitations (are scalable). toward this end, this research will focus on four transformative research initiatives: (1) defining a general-purpose formalism to promote data comprehension through knowledge-rich neural representations, (2) devising an interpretable, multi-hop inference and reasoning engine, (3) developing robust and scalable algorithms to demonstrate generalizable domain and device adaptation, and (4) building applications and datasets in question answering and fact checking tasks that will have lasting general-purpose utility. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: CAREER: Untangling Inter-Area Communication in the Brain Using Multi-Region Neural Networks

Awardee: Icahn School of Medicine at Mount Sinai

Amount: \$549,323.00

Abstract: human and animal behaviors like learning, remembering, and deciding require the interactions of neurons and circuits across regions of the brain. however, despite the importance of these interactions, remarkably little is known about the processes regulating these brain-wide communications. this research builds computer models of the brain based on measurements taken from humans and animals performing behaviors, and uses those models to identify how different brain regions communicate and work together to produce behaviors. this work will identify shared and distinct features of brain-wide communication to guide new experimental studies and enable new computer models to better define brain functions. additionally, this project promotes community engagement, **\*\*diversity\*\***, and inclusion through two complementary programs: "comp-ic book neuroscience," which brings research findings from computational neuroscience into under-served classrooms in new york city through the jargon-free and visually appealing medium of comics; and the student outreach for neuroscience integrated with cs (sonic) program, an annual lab-based summer school to give nyc-area senior college and graduate students hands-on experience with visualizing and modeling brain data. while rapid advances in neuroscience have catalyzed a deeper understanding of individual brain regions and their functions, these regions generally do not operate in isolation. yet, little is known about processes regulating the brain-wide communication underlying many behavioral outputs. to reveal fundamental principles of brain-wide communication, this project will produce (1) a new, scalable, robust, and flexible class of multi-region recurrent-neural network (rnn) models with inter-area communication; and (2) analysis methods to infer the direction and magnitude of interactions within and between areas. multi-region rnns will be constrained with real neural data to uncover mechanisms of the real biological system, for instance, how the cooperative activity of neurons within and across brain regions gives rise to complex behaviors like decision-making. reverse-engineering these models will reveal how multi-area brain circuits use biological plasticity to acquire a new skill. finally, rnn modeling of human

electrophysiology data will help identify inter-area communication processes that are conserved or divergent across multiple species. wider adoption of the new models and tools will transform the understanding of how interacting brain areas function cohesively to orchestrate complex behaviors and inform future experimental paradigms. the research will also promote cross-fertilization between neuroscience and artificial intelligence/machine learning communities, and provide quantitative techniques shared in the broader neuroscience community. furthermore, the project will foster an inclusive, welcoming environment for a diverse new generation of computational neuroscientists. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: NSF-AoF: FET: Small: Ubiquitous in-sensor computing for adaptive intelligent systems

Awardee: University of Massachusetts Amherst

Amount: \$547,998.00

Abstract: miniaturized sensor systems with built-in memory and computing functionalities are the cornerstones of artificial intelligence at the edge. however, in currently deployed systems, sensing and computing occur in separate physical locations, imposing massive data shuttling between the sensor module and the cloud-computing platform. this is unsustainable in terms of energy efficiency, latency, and capacity to process sensor data, and hence has a negative environmental impact with billions of sensors connected in the era of the internet of things (iot). the proposed project intends to go beyond state-of-the-art by system-level integration of sensing, memory, and computing functionalities into one chip, allowing for ubiquitous applications at low energy budget and low latency. furthermore, building such systems on flexible substrates will enable affordable and biodegradable smart-wearables electronics capable of monitoring human health continuously and adaptively. the proposed educational and outreach activities will promote stem careers, encourage **\*\*diversity\*\*** in engineering education and research, and significantly impact securing the future prosperity of the u.s. and the european collaborative partner (finland). the proposed research aims at delivering intelligent and energy-efficient wearable electronics that will become ubiquitous in the era of iot. the specific objectives towards this goal are as follows: 1) to design and fabricate emerging materials and devices for flexible sensors; 2) to integrate ferroelectric sensors and memristor crossbar arrays into a flexible near-sensor computing system with embedded security functionality; and 3) to demonstrate an in-sensor computing platform where emerging devices will be used as both sensing and non-volatile memory elements for in-pixel intelligent processing of images. the proposed research will enable the next-generation smart and flexible wearable electronics to process the acquired information onsite. by integrating the sensor module with the computing engine, the emerging hardware technologies will substantially improve power efficiency and computing throughput. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: BPC-A: LEAP Alliance: Diversifying Future Leadership in the Professoriate

Awardee: University of Illinois at Urbana-Champaign

Amount: \$541,167.00

Abstract: only 5.3% of the faculty at phd-granting universities are from the following underrepresented communities: black or african-american, hispanic, or american indian/alaska native. diversifying the computing professoriate is critical for providing excellent role models, shaping departmental programs and policies, and bringing diverse perspectives into research projects and programs. the leap alliance aims to increase the **\*\*diversity\*\*** of leadership in the computing professoriate by intentionally bringing together four cohorts of universities, each with common strengths and a common agenda. this work builds upon the lessons learned from a first cohort comprised of institutions producing a large percentage of computing faculty and adds three additional cohorts to further strengthen the pipeline to the computing professoriate. the goal of the leap alliance is to address the broadening participation challenge of increasing the **\*\*diversity\*\*** of the future leadership in the computing professoriate at research universities as a way to increase **\*\*diversity\*\*** across the field. key national leadership roles, such as serving on national committees that impact the field of computing, often come from research universities, making these institutions a critical point of focus. the alliance has previously piloted this effort in an initial cohort of 11 research universities who were found to produce over 50% of the faculty at the top 55 research institutions. they will continue to bring together similar institutions in a second cohort, as well as cohorts that focus on institutions graduate a large percentage of computing phds and computing undergraduates, respectively. ultimately, the alliance aims to increase the **\*\*diversity\*\*** of phd graduates from the institutions that are the top producers of computing faculty, increase the exposure of academic careers at the institutions that already have good **\*\*diversity\*\*** in their phd

graduates, and increase the retention of diverse undergraduate students at the institutions who send students to graduate school that go on to be faculty. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: CDS&E: Multi-scale Coherent Structure Extraction and Tracking For Modern CFD Data Analysis

Awardee: University of Houston

Amount: \$539,899.00

Abstract: coherent structures are persistent and recognizable patterns that can be found in fluid flows. in turbulent flows, coherent structures are closely related to a diverse range of physical phenomena, and understanding their behavior is crucial for characterizing, predicting and controlling these flows. however, reliable identification and characterization of coherent structures is challenging due to their **\*\*diversity\*\*** and complex inter-relations across different space- and time-scales. this project brings together experts from both the data visualization and fluid mechanics communities to investigate novel solutions to multi-scale coherent structure extraction, separation, tracking, and visualization. it aims at significantly advancing the ability to analyze large datasets of turbulent flows stemming from computational fluid dynamic (cfd) simulations in a wide range of engineering and scientific applications. this project provides opportunities for both undergraduate and graduate students with different and diverse backgrounds to participate in the proposed research. the research outcomes can be integrated into the development of a number of undergraduate and graduate courses taught at the university of houston. the outreach activities enabled by the proposed research help motivate more students to pursue a career in stem related fields. to achieve an efficient and reliable analysis for large-scale turbulent flow data, this project aims to investigate a new multi-scale coherent structure representation that encodes relevant flow

physics, statistics, and uncertainty information, and to develop a robust computation and exploration framework based on this new representation to support data-driven research. to enable this multi-scale analysis, this project applies a number of spatial and temporal domain decomposition strategies to the computational fluid dynamic (cfd) data. multi-field analysis and high-dimensional data projection techniques are adapted to incorporate different physical attributes to the representation. a novel graph representation is leveraged to encode this multifaceted information in a concise and dimension-independent form to enable multi-scale feature extraction and tracking. a matrix representation of this graph is employed to accelerate its processing by utilizing the recent advances in large-scale matrix calculation. a new visual analytic paradigm is devised based on the proposed graph representation to aid the exploration and comprehension of different turbulence structures individually or collectively. the developed techniques implemented as a number of software libraries can be integrated into existing software, e.g., paraview, for domain scientists to use in their daily research. the developed techniques can also be used as pre-processing toolboxes to quantify and extract coherent structures, which can then be visualized by existing software that are not suitable for direct library integration. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Edge CMT: Polygenic traits of heat stress phenome in coral "dark genes" from genome to functional applications

Awardee: University of Miami

Amount: \$537,475.00

Abstract: in this project, the researchers will use genomics, genetics, and cell biology to understand the function of coral genes during heat stress. thermal stress often causes the "bleaching" (whitening) of corals that is harming reefs worldwide and is a threat to marine biodiversity. genes

are the functional unit of dna and how the coral reacts to heat stress is called its phenotype. there are many genes involved in achieving the heat response phenotype and they will be studied in this project. this is important because the function of many of these and other genes and how they influence the phenotype of corals are not understood. in addition, many of the coral stress genes are unknown in other organisms (i.e., they arose in corals), and therefore present the opportunity to discover the function of novel genes. this research is important because it will help in the understanding of how both known and novel genes function, which can aid in the conservation of coral reefs- a resource that is important for national security and economic growth. lastly, this project will fund early career scientists and lead to broader impacts through the training and education of a diverse workforce in science. the overarching goal of this proposal is to determine the mechanistic drivers of the stress response in multicellular organisms, with a focus on the ecologically important corals. to achieve this goal, application of an end-to-end approach that extends from genes to phenotypes, to cell biology, using multi-omics and network methods with both holobiont and single cell data will be applied. this work will elucidate the coral stress phenome in species with differing reproductive strategies and geographical origins to determine the functions of both known and unknown (dark) genes. generating this knowledge base will transform coral biology and more broadly, provide a research platform for testing hypotheses about the resilience of other ecosystems, marine and terrestrial, which is particularly important under accelerating climate change. this project aims to increase the understanding and predictive capability of how key properties of living systems emerge from the interaction of genomes. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: CAREER: Topological dynamics of three-dimensional active fluids

Awardee: Brandeis University

Amount: \$535,193.00

**Abstract:** non-technical abstract spontaneous collective motion can be witnessed at different scales in nature: flocks of birds, migrating ants, and even cells within our own body moving collectively to close a wound. the goal of this research project is to better understand how these collective motions appear by employing simple three-dimensional biomimetic materials. these active materials are composed of proteins that can self-propel by harvesting energy from their environment. two types of 3d liquid crystals will be investigated where the propulsion is driven by either molecular motors or by biofilaments that grow from one end and shrink from the other, recapitulating two fundamental mechanisms employed by living cells to migrate. this research project will address how to relate the forces generated at the microscopic scale to the emergent collective properties in 3d, a critical step towards the predictive design of novel active materials for robotic or bioengineering applications. on the educational side, this project will improve **\*\*diversity\*\*** and retainment of underrepresented minorities at each academic level, from kindergarten through postsecondary education. the principal investigator will leverage the tangible nature of active matter to i) create a bilingual science children's book, ii) monthly science/pizza talks and iii) interactive demonstrations in local schools, and iv) an annual active matter bootcamp for reu students.

**technical abstract** simple biomimetic materials composed of biopolymers have become a paradigm for studying active fluids that spontaneously flow. at the macroscale, these flows often drive the nucleation of motile singularities such as topological defects. investigating such topological dynamics in 3d presents novel conceptual and experimental challenges. in addition, connecting these system-sized topological features to the microscopic driving forces is required to rigorously test hydrodynamic theories of active fluids. this career award aims to elucidate how the magnitude and the symmetry of mesoscopic active stresses drive the emergent topological dynamics of 3d active fluids with orientational order, with a particular focus on 3d active nematics and 3d polar fluids. together, these two complementary research projects provide a comprehensive description of the out-of-equilibrium hydrodynamics of motile topological defects in 3d. they will set the foundations for building

advanced biomimetic materials endowed with life-like properties. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: 21 cm Reionization Science with the MWA

Awardee: Brown University

Amount: \$534,990.00

Abstract: the epoch of reionization (eor) is the period of time in the early universe when it is thought that the first stars and galaxies formed. understanding the physics of galaxy formation and feedback during the eor is one of the key goals of modern cosmology and astrophysics. observations of neutral hydrogen in the early universe have the potential to revolutionize our understanding of these first stars and galaxies. this work will improve data analysis with the munchison widefield array telescope so that researchers can make significantly better detections of such faint signals, making the observations much more useful and providing a tool for researchers engaged in similar projects. in addition, this work will continue and expand the initiative to provide research experiences for non-traditional undergraduates. undergraduate research is an essential component in preparing students both for graduate school and for positions in the broader stem workforce. providing this kind of research experience to non-traditional undergraduate students will enable more of them to go on to graduate school, increasing the **\*\*diversity\*\*** of the broader stem community. this award supports the continued work of a successful eor analysis team. over the past four years innovations by the us imaging power spectrum (ps) team have driven the field forward and have led to the deepest eor ps limits in the world. the investigators will make the next steps needed to reduce the limits by another order of magnitude with munchison widefield array (mwa) data. specifically, this work will make improvements in ps analyses with the mwa that will lower limits on the signal strength by an order of magnitude, making deep cuts into the possible

parameter space for eor models. this research will be invaluable for the entire 21 cm community.

Title: Collaborative Research: MRA: Elucidating Plant and Mycorrhizal Fungal Relationships and Consequences across Space and Time

Awardee: University of Tennessee Knoxville

Amount: \$531,657.00

Abstract: many plants are dependent on belowground fungi to help them obtain nutrients and respond to environmental stress. revealing the patterns and drivers of these interactions is important for understanding forest ecology and improving management practices. plant-fungal associations in the soil can dramatically influence plant growth and terrestrial ecosystem function. this research will take the advantage of several existing datasets, including those collected by national ecological observatory network (neon) and the u.s. forest service (usfs), to understand: 1) nation-wide patterns of plant-fungal associations; 2) key factors that influence these associations; and 3) how plant-fungal interactions influence key ecosystem functions such as carbon cycling. this research project will contribute to the fields of microbial ecology, ecosystem science, and global change biology by formulating and testing new theories about plant-fungal associations. results of the project will inform forest managers, policymakers, and other stakeholders on how to improve ecosystem management of plant and fungal bio\*\*diversity\*\* to promote sustainable ecosystems. the project will contribute to the professional development of diverse students at several stages. the goal of this project is to understand the patterns, drivers, and consequences of the linkages between plant and mycorrhizal fungal \*\*diversity\*\* across spatial and temporal scales. this information will enable better predictive understanding of essential ecosystem functions which they control. the project will use a holistic, scale-dependent framework that forecasts the strength and direction of

arbuscular mycorrhizal (am) and ectomycorrhizal (em) fungal-plant associations, and provides greater insight about the consequences for ecosystem functioning across space and over time. specific objectives of the project include: 1) elucidation of patterns of plant and mycorrhizal fungal **diversity** across scales by extensive dna sequencing and analysis; 2) determination of key abiotic and biotic drivers of observed co-occurrence patterns; and (3) forecasting the effects of plant-mycorrhizal fungal couplings on tree productivity and soil c storage, two key forest ecosystem functions. by linking multiple facets of both above- and belowground **diversity** in a scale-dependent context, the project will produce robust continental-wide distribution maps of am and em fungi for the first time. leveraging data-rich sampling of putative biotic and abiotic drivers of plant and fungal **diversity** by neon and the usfs, the project will also provide broad-scale understanding of when and where these drivers serve to couple or decouple plant and mycorrhizal fungal **diversity**. finally, by linking plant and mycorrhizal fungal **diversity** to the consequences they have for plant productivity and soil c storage and stability, the project will improve understanding of ecosystem resilience to environmental stress. the project will train diverse undergraduate and graduate students, postdoctoral scholars, and will enhance the development of three early-career scientists. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Amount: \$531,657.00

Abstract: many plants are dependent on belowground fungi to help them obtain nutrients and respond to environmental stress. revealing the patterns and drivers of these interactions is important

for understanding forest ecology and improving management practices. plant-fungal associations in the soil can dramatically influence plant growth and terrestrial ecosystem function. this research will take the advantage of several existing datasets, including those collected by national ecological observatory network (neon) and the u.s. forest service (usfs), to understand: 1) nation-wide patterns of plant-fungal associations; 2) key factors that influence these associations; and 3) how plant-fungal interactions influence key ecosystem functions such as carbon cycling. this research project will contribute to the fields of microbial ecology, ecosystem science, and global change biology by formulating and testing new theories about plant-fungal associations. results of the project will inform forest managers, policymakers, and other stakeholders on how to improve ecosystem management of plant and fungal bio\*\*diversity\*\* to promote sustainable ecosystems. the project will contribute to the professional development of diverse students at several stages. the goal of this project is to understand the patterns, drivers, and consequences of the linkages between plant and mycorrhizal fungal \*\*diversity\*\* across spatial and temporal scales. this information will enable better predictive understanding of essential ecosystem functions which they control. the project will use a holistic, scale-dependent framework that forecasts the strength and direction of arbuscular mycorrhizal (am) and ectomycorrhizal (em) fungal-plant associations, and provides greater insight about the consequences for ecosystem functioning across space and over time. specific objectives of the project include: 1) elucidation of patterns of plant and mycorrhizal fungal \*\*diversity\*\* across scales by extensive dna sequencing and analysis; 2) determination of key abiotic and biotic drivers of observed co-occurrence patterns; and (3) forecasting the effects of plant-mycorrhizal fungal couplings on tree productivity and soil c storage, two key forest ecosystem functions. by linking multiple facets of both above- and belowground \*\*diversity\*\* in a scale-dependent context, the project will produce robust continental-wide distribution maps of am and em fungi for the first time. leveraging data-rich sampling of putative biotic and abiotic drivers of plant and fungal \*\*diversity\*\* by neon and the usfs, the project will also provide broad-scale understanding of when and where these drivers serve to couple or decouple plant and mycorrhizal

fungal **\*\*diversity\*\***. finally, by linking plant and mycorrhizal fungal **\*\*diversity\*\*** to the consequences they have for plant productivity and soil c storage and stability, the project will improve understanding of ecosystem resilience to environmental stress. the project will train diverse undergraduate and graduate students, postdoctoral scholars, and will enhance the development of three early-career scientists. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Understanding How Students' Sense of Belonging Develops During Undergraduate Field Experiences: Supports, Barriers, and Implications for Faculty

Awardee: Oregon State University

Amount: \$528,940.00

Abstract: this project aims to serve the national interest by addressing a critical need in the scholarship of stem teaching and learning. specifically, it is designed to advance understanding about how students' sense of belonging develops in undergraduate learning experiences outside of the traditional classroom. the project will focus on residential undergraduate field courses, a pivotal learning experience in stem disciplines such as ecology, geology, and geography. a sense of belonging plays an important role in students' mental health and well-being, academic achievement and motivation, and institution-level retention. it is also pivotal for the persistence of students from communities that are underrepresented in stem disciplines. the overarching goal of the project is to build the capacity of geosciences and biology faculty to support the development of students' sense of belonging. in this way, it can help to improve the inclusivity of courses that are a critical pathway for thousands of undergraduate students in field-based stem disciplines. this project has the potential for broad reach and impact on student engagement and learning in multiple stem disciplines and is likely to have a positive impact on the inclusivity of undergraduate field education.

it may be especially important for students from communities that have been historically excluded from field-based stem disciplines, whose persistence is strongly linked to sense of belonging in the scientific community. the project focuses on advancing understanding about how students' sense of belonging develops in residential field experiences and builds capacity for faculty from geosciences and biology to support the growth of students' sense of belonging. the following objectives will guide the project study: 1) identify factors that contribute to and hinder the development of students' sense of belonging during residential geosciences and biology undergraduate field courses; 2) characterize the design and implementation of geosciences and biology undergraduate field courses, specifically what practices faculty are using and what challenges and needs exist for the development of students' sense of belonging during undergraduate field courses; 3) create an empirically-based framework of how students' sense of belonging develops during residential undergraduate field courses; 4) facilitate a community of practice that uses and contributes to promising practices for the design and assessment of inclusive field courses that support the development of students' sense of belonging; and 5) articulate a suite of promising practices that have the potential to promote the development of students' sense of belonging during a range of formats of undergraduate field courses and for students from different backgrounds. using innovative and robust mixed methods research approaches, this work will contribute to the wider body of evidence-based, student-centered practices in undergraduate stem education. the work has the potential to provide a deep and impactful contribution to the fields of discipline-based education research (particularly in geosciences and biology), higher education, education and social psychology, and **\*\*diversity\*\***, equity, and inclusion. the nsf iuse: ehr program supports research and development projects to improve the effectiveness of stem education for all students. through the engaged student learning track, the program supports the creation, exploration, and implementation of promising practices and tools. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: BRITE Pivot: Micro-Macro Modeling of Reactive Flow and Rock Weathering Enhanced by Artificial Intelligence

Awardee: Georgia Tech Research Corporation

Amount: \$525,070.00

Abstract: reactive flow is key to geomechanical instabilities that occur over spatiotemporal scales spanning several orders of magnitude. it is particularly challenging to formally link the microstructure changes induced by chemical reactions and pore deformation to measurable physical and mechanical properties, because the microstructural features that govern macroscopic fluid flow differ from those that dominate elastic, plastic and brittle behaviors. this boosting research ideas for transformative and equitable advances in engineering (brite) pivot award will deploy artificial intelligence (ai) strategies to predict the spatiotemporal scales of thermo-hydro-chemo-mechanical (thcm) instabilities and automatically adapt the representation of the microstructure as localizations occur. this adaptive multi-scale modeling approach will help improve the safety and sustainability of long-term underground geological storage facilities and understanding of chemical weathering processes in the bedrock, which play a central role in nutrient supply, landslide hazards, and the global carbon cycle. the integration of computer science, applied mechanics, geotechnical engineering and geomorphology aims to grow convergence research towards the design of new materials and the fundamental understanding of the behavior of solid and soft matter, hence providing new modeling tools to decipher the rules of life and harness the data revolution through deep neural networks that will highlight hidden correlations between topological features and phenomena. the pi will create multi-semester undergraduate research opportunities and international research experiences for students, develop a **\*\*diversity\*\***/equity/inclusion (dei) seminar series and co-design innovative inclusion metrics in engineering. the exploration of ai for computational geomechanics is at its infancy. the researched integration of ai with the

homogenization theory will spearhead impactful advances in applied mechanics, including the modeling of open thermodynamic systems, the development of a new class of adaptive micro-macro models and applications over a wide range of spatiotemporal scales. the research plan will integrate training, research, dissemination and dei activities for the pi and the students involved in the project, and will be organized around the five following scientific objectives: (1) construct a database of virtual experiments of confined reactive flow with a full-field method; (2) train and test a deep convolutional neural network (cnn) to recognize microstructural features that attract high spatiotemporal variations of field variables; (3) enrich eshelby's homogenization theory with inclusion-specific characteristic times; (4) train and test a deep cnn to adapt the homogenization scheme as a function of the microstructure changes and localizations that occur after characteristic times have elapsed; (5) solve coupled thcm boundary-value problems of geomechanics with the adaptive homogenization method. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Self-Assembly of Multicomponent Nanostructures

Awardee: Ohio State University

Amount: \$525,000.00

Abstract: with the support of the macromolecular, supramolecular and nanochemistry program in the nsf division of chemistry, professor jon parquette of ohio state university will develop new strategies to construct multicomponent nanomaterials via the self-assembly of simple building blocks. the capability to build abiological nanomaterials comprised of discrete, self-sorted domains is expected to enable the emergence of novel properties that will drive the development of novel biomaterials, drug delivery modalities, catalysts, and optoelectronic materials. this work will create a platform to also address other problems in human health and society, such as renewable energy, greenhouse

gas conversion, and medicine. this project will be used to enhance public awareness of nanoscience in society and will expose a **\*\*diversity\*\*** of students to scientific research. the pi will achieve these goals by supervising undergraduate and high school students in research, by mentoring undergraduate career clubs, and by participating in science exhibitions at columbus center of science and industry (cosi) as a member the center of applied plant science (caps) at ohio state university. this research aims to gain a better fundamental understanding of the factors that govern "self/non-self" interaction at the nanostructure level and to establish new design principles to construct multicomponent hierarchical architectures by the coassembly of spatially sorted domains of components. this is important because the nanoscale organization of the components of an assembled structure critically impacts the functional attributes of a nanomaterial. the first aim of this work will construct block sequences of two types of supramolecular rings within a self-assembled nanotube via a heterogeneous nucleation-elongation mechanism. the second aim facilitates the interactions between the separate domains by incorporating an intervening polydopamine layer to stabilize one component and mediate further interactions with additional assembled structures. transient nanostructures that only persist in the presence of fuel play critical roles in living cells, such as controlling the mechanical properties of the cytoskeleton. thus, the third aim of this work will focus on the design of transient multicomponent hydrogels that exhibit time-dependent physical/optical characteristics, whose temporal evolution can be directly visualized using confocal light microscopy.

this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: IntBIO COLLABORATIVE RESEARCH: Integrating trait diversity across hierarchical scales to predict biological resilience in an era of extreme environmental change

Awardee: University of North Carolina Greensboro

Amount: \$524,421.00

Abstract: extreme climate events, such as drought or wildfire, may occur in high frequency and/or in tandem. these extremes are likely to occur more frequently over the coming decades and will likely have more severe effects on natural and human landscapes than when extreme events occur alone. many parts of southern africa suffered the effects of compound extremes in 2015 and 2016 when drought and heavy wildlife use caused substantial declines in vegetative cover and mass wildlife mortality in national parks. many areas are yet to fully recover. ecosystem recovery after compound extremes is critical for maintaining important services that landscapes provide, such as wildlife habitat, food production, and carbon storage. the mechanisms behind recovery after extreme events are not well understood, although there is mounting evidence that the **diversity** of organisms (i.e., **bio**diversity****) within ecosystems may be key. this award will experimentally impose compound extremes in a south african savanna and incorporate measured outcomes into computer models to understand how **diversity** of plant life controls ecosystem recovery after compound extremes. the information and tools created by this project will be important for land managers and policy makers to maximize the recovery potential of public and private lands through the promotion of **bio**diversity****. additionally, this project will provide important training and education opportunities for a diverse assemblage of people (local south african stakeholders, high school, undergraduate and graduate students, and postdoctoral scholars), and will prioritize advancement of **diversity**, equity, and inclusion in the sciences. currently, the importance of **bio**diversity**** for ecosystem recovery (i.e., resilience) is recognized at the community level, but the mechanisms underlying species **diversity** that can extend these concepts to other spatial and hierarchical scales are not

well understood. organismal traits provide a useful framework for understanding these mechanisms because the coordination of physiological, morphological, and anatomical characteristics determine the response of individuals to their environment; this facilitates scaling from organisms to populations, communities, and ecosystems using first principles. this study will first extend bio\*\*diversity\*\*-resilience ideas beyond simple species \*\*diversity\*\* by using methods to examine \*\*diversity\*\* of plant traits (e.g., functional dispersion). second, it will scale bio\*\*diversity\*\*-resilience relationships from individual organisms, through populations and communities, to entire ecosystems. to these ends, this project will experimentally impose extreme drought, extreme grazing, and extreme fire, singly and in combination, in a south african savanna and determine (1) \*\*diversity\*\* of functional traits before, during, and after treatments to link with (2) responses of individuals, populations, communities, and the ecosystem during and after treatments. empirical data will then be used to parameterize and benchmark a mechanistic demographic vegetation model to expand the inference of these effects to longer time frames and a wider range of bio\*\*diversity\*\* scenarios. the three overarching questions this project will address are: (1) how does \*\*diversity\*\* at different hierarchical scales control resilience of biological function after perturbations? (2) how do perturbations affect bio\*\*diversity\*\* at multiple hierarchical scales? (3) how does \*\*diversity\*\* and resilience change with frequency and compound perturbations? this project is jointly funded by emerging frontiers in the directorate for biological sciences and the established program to stimulate competitive research (epscor). this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: CCRI: New: Medium: A Development and Experimental Environment for Privacy-preserving and Secure (DEEPSECURE) Machine Learning

Awardee: SUNY at Buffalo

Amount: \$520,000.00

Abstract: while machine learning (ml) is embraced as an important tool for various science, engineering, medical, finance, and homeland security applications, it is becoming an increasingly attractive target for cybercriminals. deepsecure is a first-of-its-kind development and experimental platform to support secure and privacy-preserving ml research. with its novel modular design

integrated with fully customizable function blocks and sample modules, deepsecure is a game-changing tool to effectively support research in this emerging field by enabling fast design, prototyping, evaluation, and re-innovation of trust-worthy ml applications. it enables a variety of compelling new research projects that focus on ml security and privacy, leading to breakthroughs to protect ml systems and accelerating their development and widening their adoption. it will contribute significantly to the protection of the future cyber and physical world and safeguard human society. deepsecure receives strong community support from over 20 key stakeholders across the country. the project includes significant efforts for fostering and sustaining an ml security and privacy research community, including monthly virtual open forums to provide a regular update to and seek feedback from the community, quarterly advisory board meetings, annual symposiums, and a training workshop series. the project includes specific measures and plans for inspiring the participation of underrepresented groups and infusing **\*\*diversity\*\*** and inclusion in all deepsecure events and activities. the project output includes an open-source and easy-to-use learning platform for curriculum development and workforce training. to support building a sustainable workforce development pipeline, the project team participates in the existing annual gencyber summer camps for k-12 students and a cyber saturday series to introduce cybersecurity and ai career paths and educational resources to k-12 school counselors, teachers, students, and parents. recent development in privacy-preserving and secure ml draws expertise from both ml and security/privacy to tackle the multi-faceted problem. however, the research community is facing fundamental challenges in this emerging area due to its interdisciplinary nature. on the one hand, although deep learning frameworks such as pytorch and tensorflow have been made widely available, a critical hurdle faced by ml researchers is the steep learning curve to effectively use security techniques and libraries to tackle ml security and privacy problems. on the other hand, while the security community has developed highly efficient cryptographic libraries, it remains nontrivial to integrate them into deep learning models to achieve a computation efficiency suited for practical applications. the overarching goal of the project is to close the gap by developing deepsecure, which integrates a

spectrum of essential functions and building blocks that are ready-to-use to flatten the learning curve for researchers coming from both ml and security/privacy communities. at the same time, deepsecure is fully customizable and scalable, enabling deep and fundamental research toward privacy-preserving and secure ml. to meet the overarching goal, specific project objectives include: (1) acquiring a scalable and re-configurable compute environment based on the latest dell, amd, and nvidia technologies to establish the deepsecure hardware infrastructure across the campuses of old dominion university and university of buffalo; (2) developing a new software platform to support deepsecure sde (software development environment) and mec (multi-user experimental chamber). the platform is integrated with pytorch to enable great usability for both beginners and advanced researchers and feature a scalable and customizable modular framework with seamlessly integrated libraries, function blocks, and sample modules; (3) promoting deepsecure across the nation to ensure broad participation, collaboration, and sharing; (4) leveraging deepsecure to foster a long-lasting, self-sustainable ml security and privacy research community that engages all stakeholders in a sustained and ongoing way; and last but not least, (5) educating and training diverse cybersecurity workforce to safeguard the future intelligent cyber systems. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Tuning Teflon-Coated Earth-Abundant Metal Complexes in Oxidative Catalysis

Awardee: Trustees of Boston University

Amount: \$518,135.00

Abstract: with the support of the chemical catalysis program in the division of chemistry, professor linda doerrer of boston university and professor kimberly ann stieglitz of roxbury community college will study the specific conversion of carbon-hydrogen bonds to carbon-oxygen and carbon-carbon

bonds. these oxidation reactions are widespread and critical reactions in modern chemistry. the cheapest and most sustainable oxidant is atmospheric oxygen ( $\text{O}_2$ ) but oxygen also is capable of oxidatively inactivating many catalyst systems. almost all catalysts that utilize  $\text{O}_2$  in these oxidation reactions contain transition metals that enable these reactions to take place. this work will expand on current efforts to prepare new Cu catalysts supported by fluorine-rich "teflon-coated" ligand systems that provide stability to the molecular catalysts. the researchers will prepare new compounds in which clamping ligands hold metal atoms tightly to control reactivity between  $\text{O}_2$  and the substrate. the project will also probe oxidations using other metals besides Cu, particularly with Mn and V, and will extend the research to Fe-containing systems. an important thrust will be the development of catalysts that perform well in water and air to make these hydrocarbon oxidation systems more sustainable and environmentally friendly. the broader impacts of this work will involve undergraduate course development, student training, and a productive collaboration between Boston University and Roxbury Community College. Roxbury Community College delivers instruction to a high percentage of students from underserved minority groups; thus this collaborative effort will be directed at increasing **diversity**, equity, and inclusion in STEM (science, technology, engineering and mathematics) fields.

in these studies, professors Linda Doerr of Boston University and Kimberly Ann Stieglitz of Roxbury Community College will study the oxidation of C-H bonds. this work builds on prior work of the researchers on Cu/ $\text{O}_2$  chemistry that has demonstrated the effectiveness of fluorinated alkoxide ligands to make highly reactive species for oxidizing C-H bonds. the nature and degree of encapsulation of redox inert counter cations, specifically K, on the catalytic activity will be investigated. other counter cations of Li, Na, Rb, and Cs will also be pursued, as will an Fe-based catalysts system which will be accessed via two complementary routes. a Bordwell square approach will be used to generate a proposed  $\{\text{Mn(III)OH}\}$  reagent in situ that will be used to probe its thermodynamic properties. exploration of the scope and optimization of reaction conditions with a benchtop-stable vanadium compound capable of catalytic C-H bond oxidation will be part of a hands-on experimental synthesis and spectroscopy class taught at Roxbury Community College by

the collaborative team. this continued collaboration brings together expertise in transition metal complexes (doerrer) and in organic compound characterization (stieglitz), and will enhance the training of underrepresented minority students for stem careers while exposing them to research at an r1 university. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Excellence in Research: Investigation of Interfacial Chemical and Ion Transport in Solid Inorganic-Polymer Electrolytes

Awardee: Xavier University of Louisiana

Amount: \$513,443.00

Abstract: limited understanding ion transport at the interfaces in electrochemical systems is a major obstacle in the development of safe, reliable advanced lithium batteries with ultra-high energy density and high power-density. such batteries are needed for the widespread electrification of transportation and storage of renewably generated electricity. fundamental understanding of ion transport and control of interfacial reactions between a composite electrolyte and electrodes will enable engineering of new interfaces containing safer, solid polymer-based composite electrolytes. in this project, the researchers will investigate ion transport at the boundaries of the electrolyte/electrodes as well as between the ceramic/polymer matrix. the team will utilize several different characterization tools to understand the properties of the materials. the students involved in this research project will be engaged in cutting-edge research on a topic of importance to addressing the global energy challenge. this project will contribute to improving **\*\*diversity\*\*** in the stem (science, technology, engineering, and mathematics) workforce by recruiting and retaining highly qualified students from underrepresented minority groups and engaging these students in cutting-edge research and development in energy storage technologies. the overall collaboration

between xavier university of louisiana (xula) and the university of notre dame (nd) which includes summer visits of undergraduate xula researchers to the nd research group will enhance the students' research experiences, promote retention of underrepresented minority students in stem fields, and enable research not possible by either group individually. interfacial research is critically needed for designing new solid electrolyte systems with both high bulk ionic conductivity and that is chemically and dimensionally stable against the li anode with cycling. composite polymer electrolytes have flexibility necessary to withstand electrode volume changes with cycling, yet ion transport is limited between the ceramic and polymer in the bulk electrolyte and between the composite and the electrode surface. the interfacial resistances lead to reduced bulk ionic conductivities, reduced safely achievable cycling rates, and poor li anode performance. in this project by researchers at xula and nd, the interfacial chemistry and ion transport within the system including composite polymer electrolytes and li anodes will be investigated as a function of polymer type to allow for the fundamental understanding of each chemistry and polymer dynamics on interfacial properties. these studies will test the hypotheses that nanoscale void formation between the electrolyte and anode, as well as between ceramic and polymer matrix, causes roughness and small contact area for ion transport which increases the interfacial resistance, and a lithium deficient layer at the interface leads to the formation of space-charge which also contributes to interfacial resistance. this project is jointly funded by the established program to stimulate competitive research (epscor), and the broadening participation in engineering program. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: IntBIO Collaborative Research: An integrative approach for projecting insect responses to a rapidly changing climate

Awardee: University of Alaska Fairbanks Campus

Amount: \$511,073.00

Abstract: projecting species' responses to climate change at continental scales is a current 'grand challenge' of ecological research. insects are sensitive indicators of both climate and land-use change and recent studies indicate widespread declines in many geographic regions. to predict changes across entire ranges, a variety of species distribution models have been developed, but rarely account for regional variability, ecological interactions or a species' potential to adapt to changing conditions. this project spans multiple institutions situated in the united states' southwest, polar north, and temperate eastern regions. a series of physiological experiments will be implemented for five widespread butterfly species with populations sourced from different biomes within each of their ranges. caterpillars will be subjected to a range of conditions mimicking past, current and future climates. their development rate, survivorship, immune response, and genetic

structure and gene expression (which genes are actively coding for proteins) will be measured and used to build models that predict distributional shifts. data collected by community (?citizen?) scientists will be used to validate the models. this project requires substantial cross-disciplinary collaboration, and a central goal is to recruit diverse trainees at the graduate and undergraduate levels and train them in the ?science of team science?. project trainees will develop independent research ideas that align with and expand the project?s scope and travel between and work at collaborating institutions as an inter-lab exchange to learn new techniques and be exposed to different research philosophies. finally, the project has significant management implications for insect bio\*\*diversity\*\* conservation. projecting responses to climate change at continent scales is a current ?grand challenge? of ecological research. insects are the most diverse and ecologically important terrestrial animal taxon and are strongly affected by climate change. to predict changes, species distribution models (sdms) have been widely implemented across many taxa. sdms, however, rarely account for ecological interactions, plasticity or evolutionary adaptive potential owing to the extensive physiological and ecological data required to parameterize such models. the biology of lepidoptera, particularly butterflies, is extremely well observed, thus it is logistically feasible to build upon past knowledge and collect additional data that enables mechanisms to be more seamlessly integrated into sdms. multiple populations for each species will be sourced from different biomes across its range. caterpillars will be reared in common gardens under a range of temperature conditions mimicking past, current and future climates. their development rate, survivorship, immune response, genetic structure and gene expression will be measured and used to build models that predict future distributions. distribution data collected by community (?citizen?) scientists will be used to validate and improve models and allow robust estimates of uncertainty. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: CAREER: Models and Algorithms for Strategic Conservation Planning

Awardee: Arizona State University

Amount: \$511,057.00

Abstract: this faculty early career development program (career) award will contribute to the national health, prosperity, and welfare by improving decision-making in conservation planning through new theory, models, algorithms, and visual analytics tools for landscape and conservation ecology. bio\*\*diversity\*\* has been declining at rapid rates during the last several decades due to habitat loss, landscape deterioration, environmental change, and human-related activities that directly and indirectly affect natural habitats. in addition to its economic and cultural value, bio\*\*diversity\*\* plays an important role in keeping an environment?s ecosystem in balance. disrupting such processes can reduce the provision of natural resources such as food and water, which in turn yields a direct threat to human health. protecting natural areas is fundamental to preserving bio\*\*diversity\*\* and to

mitigate the effects of ongoing environmental change. this award will contribute quantitative methods to support informed decisions on conservation design and effective land use to support species sustainability. these methods integrate realistic ecological features, specific spatial properties of the selected reserves (e.g., connectivity), population dynamics within the spatial assets, and the impact of current and future threats. the educational plan will improve the skills and **diversity** of future generations of engineers via technical training and engagement in transdisciplinary research. the outreach activities aim to increase the students' awareness of current bio**diversity** and conservation challenges. this award supports fundamental research on the design of portfolios of land or marine patches to support species sustainability. these design problems result in very large mixed-integer linear programs whose solutions require innovative formulations and new large-scale optimization methods. the new models and specialized algorithms will allow decision-makers to solve a variety of realistic large-scale corridor and reserve design problems that include patch-specific conservation decisions under spatial, operational, ecological, and biological requirements. these models will feature realistic objectives faced by practitioners, such as maximization of the protected area or the number of species covered and minimization of the conservation cost. the design models will embed stochastic processes to capture the species' spatiotemporal movement across the landscape and to assess the effectiveness of conservation plans, including extinction risks, mortality, and ecosystem disturbances. new bi-level and stochastic optimization models and algorithms will support the design of robust conservation areas, i.e., areas that provide acceptable levels of ecological benefits even under future extreme and adverse events affecting the landscape. a visual analytics tool will integrate the developed tools, facilitating the discussion of optimal conservation plans with practitioners, advocates, and experts. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Varieties of Crises, Elite Responses, and Executive Approval

Awardee: Georgia State University Research Foundation, Inc.

Amount: \$510,490.00

Abstract: this award is funded in whole or in part under the american rescue plan act of 2021 (public law 117-2. this project examines four major types of crises -- economic, security, natural disaster, and public health crises ? and how they influence public support for political leaders in contemporary democracies. this is important to understand because leader approval is a key barometer of policymaker accountability and democratic stability, both of which can be undermined by crises. this project analyzes the interplay of four factors which vary systematically across these different types of crises and how, in turn, these shape public evaluations of political executives: (1) the ability of citizens to assign responsibility for policy decisions and outcomes; (2) the degree of expert consensus on effective policy response; (3) how much a given crisis in one area generates acute challenges or crises in other areas; and (4) the extent to which an effective response depends on citizens acting collectively. several data sets including (quarterly) measures of executive approval

and crises; the tone and salience of leader messaging about the crises; the media's treatment of leader messaging; and (monthly) leader approval for a smaller number of countries for which such data is available; and survey-based experiments in three countries are collected and made publicly available. the award supports education and **\*\*diversity\*\*** by building the research capacity of a student project lab at georgia state university, a minority serving institution, in coordination with pis at four other universities who will also engage graduate and undergraduate students in this work.

puzzling divergences across countries in public reactions to leader responses to the covid-19 public health crisis have revealed major gaps in our understanding of how crisis events translate into public assessments of leaders. to resolve these puzzles, this project advances a unifying theoretical framework that identifies four major types of crises: economic, security, natural disaster, and public health. it then locates these crises on four key dimensions which should condition public support of top officials: the institutional and political context and other factors that impact attribution of responsibility, degree of expert consensus and incentives for politicians to follow expert recommendations, the likelihood and nature of spill-over to other crisis types, and the degree to which citizen action is required for an effective response. the project collects data to test theoretically-motivated hypotheses using: 1) a macro time-series cross-national data set to study the effects of crisis type on public approval for political executives for 48 countries, 2) a high-frequency time-series data set appropriate to test how approval dynamics reflect leader responses, as well as messaging choices and media effects for 18 countries for which this data is available, and 3) conjoint experiments in france, italy, and mexico, countries with different political and institutional settings, to assess the validity of the links between crisis types and dimensions as well as to validate proposed individual-level mechanisms. this project is supported by the accountable institutions and behavior program and the sbe build and broaden program. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Instrument Development: Creating a Tunable, Broad bandwidth 2D IR Microscope for Quantitative Imaging of Chemical Dynamics Near Reactive Surfaces

Awardee: Colorado State University

Amount: \$510,200.00

Abstract: with the support of the chemical measurement and imaging (cmi) program in the division of chemistry, amber krummel of colorado state university will study the structures and motions of molecules near electrode surfaces. a major goal is to produce molecular snapshots during the formation and growth of the solid electrolyte interphase (sei) in a model electrochemical cell. the electrolytes and electrodes used in this project will be chosen to closely model organic battery electrolytes and half-cells contributing to emerging energy storage technologies. dr. krummel and her group will be building new capabilities into an emerging imaging technique? 2-dimensional infrared (2d-ir) microscopy. 2d-ir microscopy holds the promise of visualizing the "molecular dance" taking place near electrode surfaces, due to its ability to provide chemical information at ultrafast time scales and its sensitivity to different types of molecular structures. the efforts supported by this funding will produce new chemical imaging tools crucial to many disciplines of science and technology, such as electrochemical processes associated with clean energy technologies, materials science, biotechnology, and geology. the results of the imaging experiments are expected to provide insights into the fundamental characteristics of sei, which is key for understanding device performance issues encountered in energy storage technologies. further broadening impacts of the project are dr. krummel is helping to train the next generation of spectroscopists and microscopists in the areas of physical chemistry, laser physics, and materials chemistry. the primary goal of building a tunable, broad bandwidth 2d-ir microscope will require integration of knowledge in optical physics, imaging, and ultrafast nonlinear optical spectroscopy tools. finally, through hands-on mentoring, the researchers in the krummel group will learn the art of communicating their innovations to broad audiences and principles of community through direct training in **\*\*diversity\*\***,

equity, inclusion, and social justice issues within their communities. developing an imaging modality capable of reporting chemical dynamics at ultrashort timescales and then connecting the observed dynamics to macroscopic observables is extremely attractive. two-dimensional infrared (2d-ir) spectroscopy is a proven tool for capturing information on chemical structures and dynamics at femtosecond timescales and longer, which limits its recording chemical information about reactions that are extremely fast and key to many crucial chemical processes. this project is expected to significantly reduce the acquisition time of 2d ir spectra, thus making it possible to develop new 2d-ir imaging tools to directly measure molecular interactions across multiple length scales. the scientific inquiry outlined in this project aims to create a new nonlinear optical microscopy tool capable of mapping chemical interactions. the chemical interactions that will be mapped are expected to contain quantitative details of dynamic behaviors in electrolytes near electrode surfaces. the research team will initiate in situ imaging of molecular structures and dynamics during solid electrolyte interphase formation for the first time. these experiments have to potential to increase knowledge of fundamental driving forces present during sei formation at electrode surfaces, providing crucial control parameters of the sei, as well as demonstrating the utility of 2d-ir imaging across a range of scientific disciplines. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Edge CMT: Polygenic traits of heat stress phenome in coral "dark genes" from genome to functional applications

Awardee: Rutgers University New Brunswick

Amount: \$509,125.00

Abstract: in this project, the researchers will use genomics, genetics, and cell biology to understand the function of coral genes during heat stress. thermal stress often causes the "bleaching" (whitening) of corals that is harming reefs worldwide and is a threat to marine biodiversity. genes are the functional unit of dna and how the coral reacts to heat stress is called its phenotype. there are many genes involved in achieving the heat response phenotype and they will be studied in this project. this is important because the function of many of these and other genes and how they influence the phenotype of corals are not understood. in addition, many of the coral stress genes are unknown in other organisms (i.e., they arose in corals), and therefore present the opportunity to discover the function of novel genes. this research is important because it will help in the

understanding of how both known and novel genes function, which can aid in the conservation of coral reefs- a resource that is important for national security and economic growth. lastly, this project will fund early career scientists and lead to broader impacts through the training and education of a diverse workforce in science. the overarching goal of this proposal is to determine the mechanistic drivers of the stress response in multicellular organisms, with a focus on the ecologically important corals. to achieve this goal, application of an end-to-end approach that extends from genes to phenotypes, to cell biology, using multi-omics and network methods with both holobiont and single cell data will be applied. this work will elucidate the coral stress phenome in species with differing reproductive strategies and geographical origins to determine the functions of both known and unknown (dark) genes. generating this knowledge base will transform coral biology and more broadly, provide a research platform for testing hypotheses about the resilience of other ecosystems, marine and terrestrial, which is particularly important under accelerating climate change. this project aims to increase the understanding and predictive capability of how key properties of living systems emerge from the interaction of genomes. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: WINTRE-MIX: Winter Precipitation Type Research Multi-scale Experiment

Awardee: University of Wyoming

Amount: \$507,753.00

Abstract: during near-freezing weather conditions, a **\*\*diversity\*\*** of surface precipitation types are possible, including: rain, drizzle, freezing rain, freezing drizzle, wet snow, ice pellets, and snow. such near freezing precipitation affects wide swaths of the united states and canada, impacting aviation, road transportation, power generation and distribution, winter recreation, ecology, and hydrology.

this award is for a field experiment, named the winter precipitation type research multi-scale experiment (wintre-mix) with the overarching goal of improving understanding of how a variety of processes influence the variability and predictability of the type and amount of precipitation that falls during winter weather events. the project has direct societal impact through the potential for improved forecasting of these events. additionally, the project will have significant student involvement, public outreach events, and citizen science participation. the wintre-mix campaign will be conducted in southern quebec, canada and northern ny and vt in the united states. the canadian national research council convair-580 research aircraft and the university of illinois mobile radars will be deployed along with a host of surface-based instrumentation in february and march of 2022 to make observations that can be used to determine the thermodynamic, dynamic, and microphysical processes that interact to determine near-freezing precipitation type. more specifically, the project has three overarching scientific questions that will be addressed using observations, analysis, and modeling: 1) how do mesoscale dynamics modulate near-freezing precipitation, 2) how do microscale processes modulate near-freezing precipitation, and 3) how do multi-scale processes combine to determine the predictability of near-freezing precipitation? this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: CAREER: Development and Application of First-Principles Dielectric Embedding Many-Body Perturbation Theory for Heterogeneous Interfaces

Awardee: Wayne State University

Amount: \$507,453.00

Abstract: nontechnical summary      this career award supports research and education in computational and theoretical condensed matter and materials physics. the research part of this

project focuses on the development and application of new computational tools to study the electronic properties of heterogeneous interfaces formed between molecules and solid substrates. such interfaces find broad applications in energy conversion materials, such as photovoltaics that convert solar energy into electric current and photocatalytic materials that harvest solar light to drive chemical reactions. to understand and control these complex processes at a fundamental level, it is essential to accurately describe the electronic structure based on quantum mechanical simulations of the materials. given the large system size and the accuracy needed to quantitatively understand the energy conversion mechanisms at heterogeneous interfaces, most conventional simulation methods are unfortunately either inefficient or inaccurate. the objective of the research part of this project is to develop a suite of new computational schemes that are both accurate and efficient in the characterization of the electronic structure at heterogeneous molecule-substrate interfaces. these methods will significantly expand the scope of materials and interfaces that can be routinely modeled as compared to the current state of the art. the basic idea is to divide the interface into its smaller constituents or building blocks and then treat each component with high-level theory while considering it embedded in the environment of the others. using this embedding approach, the team will quantitatively investigate how the electronic structure of each component of the interface is affected by the others, and how the electronic structure of the entire interface is different from those of the individual constituents. the team will apply the new computational approach to a few emerging systems of experimental significance, especially interfaces involving multiple light absorbers and interfaces featuring electronic and optical properties which differ considerably when measured in different directions. the research will lead to new insights into energy conversion mechanisms and the rational design of new energy materials. the research activity is closely integrated with the education and outreach parts of this project. the pi will organize a summer camp annually for local high school students in the southeastern michigan area, promoting the awareness of the importance of computation and its power in scientific research. the summer camp also addresses the **\*\*diversity\*\*** challenge in science, technology, engineering, and mathematics in the metropolitan

detroit area. additionally, the pi will provide summer intern positions in his research group for local high school students and teachers, broadening the impact of the pi's undertaking in educating the next generation of scientists beyond training graduate students. furthermore, the pi will continue the development of a computational chemistry course at wayne state university for both undergraduate and graduate students. the pi will continuously add course content based on his research expertise in materials chemistry and customize the topics to meet the research needs of the enrolled students. moreover, the pi plans to organize mini-workshops on the basic use of mathematical software in the chemistry department at wayne state university for both undergraduate and graduate students, offered twice a year, as an endeavor to mitigate the students' common math anxiety in the learning of science courses.

technical summary      this career award supports research and education in computational and theoretical condensed matter and materials physics. the research part of this project focuses on the development and application of new computational methods to study the quasiparticle electronic structure and optical excitations at heterogeneous interfaces formed between molecules and solid substrates. such interfaces are ubiquitous in nanoscale energy conversion applications, such as photovoltaics and photocatalysis. although many-body perturbation theory such as the gw-bse formalism (g is the green's function, w is the screened coulomb interaction, and bse stands for bethe-salpeter equation) provides a rigorous theoretical framework, first-principles calculations of large molecule-substrate interfaces are computationally expensive. lack of efficient yet reliable computational schemes for large heterogeneous interfaces hinders fundamental understanding of the molecule-substrate interactions and interfacial charge dynamics.

the research part of this project aims to develop a suite of new tools, termed as "dielectric embedding gw-bse", to make such calculations practically affordable for large interfaces without sacrificing accuracy. the essential idea is to confine explicit gw-bse calculations within each component of the interface while treating the effect of the others as a dielectric environment. this project will leverage the newly developed methods to study a few systems of experimental significance, including: (1) interfaces formed between monolayer transition-metal dichalcogenides

(tm<sub>2</sub>S<sub>2</sub>) and (metallo)phthalocyanines, where the gaps and excitons of both components as well as the valley pseudospin of the tmd substrates within the interface will be studied; (2) interfaces involving black phosphorus, where the anisotropy of the dielectric screening at such interfaces will be scrutinized; and (3) charge-transfer systems modulated by interfaces, such as molecular donor-acceptor pairs adsorbed on metal or semiconductor substrates and large organic adsorbates on bilayer tm<sub>2</sub>S<sub>2</sub> featuring inter-layer charge-transfer excitons. the research activity is closely integrated with the education and outreach parts of this project. the pi will organize a summer camp annually for local high school students in the southeastern michigan area, promoting the awareness of the importance of computation and its power in scientific research. the summer camp also addresses the **\*\*diversity\*\*** challenge in science, technology, engineering, and mathematics in the metropolitan detroit area. additionally, the pi will provide summer intern positions in his research group for local high school students and teachers, broadening the impact of the pi's undertaking in educating the next generation of scientists beyond training graduate students. furthermore, the pi will continue the development of a computational chemistry course at wayne state university for both undergraduate and graduate students. the pi will continuously add course content based on his research expertise in materials chemistry and customize the topics to meet the research needs of the enrolled students. moreover, the pi plans to organize mini-workshops on mathematica and wolframalpha in the chemistry department at wayne state university for both undergraduate and graduate students, offered twice a year, as an endeavor to mitigate the students' common math anxiety in the learning of science courses. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

technical summary    this career award supports research and education in computational and theoretical condensed matter and materials physics. the research part of this project focuses on the development and application of new computational methods to study the quasiparticle electronic structure and optical excitations at heterogeneous interfaces formed between molecules and solid substrates. such interfaces are ubiquitous in nanoscale energy conversion applications, such as photovoltaics and photocatalysis. although many-body perturbation theory such as the gw-bse formalism (g is the green's function, w is the screened coulomb interaction, and bse stands for bethe-salpeter equation) provides a rigorous theoretical framework, first-principles calculations of large molecule-substrate interfaces are computationally expensive. lack of efficient yet reliable computational schemes for large heterogeneous interfaces hinders fundamental understanding of the molecule-substrate interactions and interfacial charge dynamics.

the research part of this project aims to develop a suite of new tools, termed as "dielectric embedding gw-bse", to make such calculations practically affordable for large interfaces without

sacrificing accuracy. the essential idea is to confine explicit gw-bse calculations within each component of the interface while treating the effect of the others as a dielectric environment. this project will leverage the newly developed methods to study a few systems of experimental significance, including: (1) interfaces formed between monolayer transition-metal dichalcogenides (tmds) and (metallo)phthalocyanines, where the gaps and excitons of both components as well as the valley pseudospin of the tmd substrates within the interface will be studied; (2) interfaces involving black phosphorus, where the anisotropy of the dielectric screening at such interfaces will be scrutinized; and (3) charge-transfer systems modulated by interfaces, such as molecular donor-acceptor pairs adsorbed on metal or semiconductor substrates and large organic adsorbates on bilayer tmds featuring inter-layer charge-transfer excitons. the research activity is closely integrated with the education and outreach parts of this project. the pi will organize a summer camp annually for local high school students in the southeastern michigan area, promoting the awareness of the importance of computation and its power in scientific research. the summer camp also addresses the **\*\*diversity\*\*** challenge in science, technology, engineering, and mathematics in the metropolitan detroit area. additionally, the pi will provide summer intern positions in his research group for local high school students and teachers, broadening the impact of the pi's undertaking in educating the next generation of scientists beyond training graduate students. furthermore, the pi will continue the development of a computational chemistry course at wayne state university for both undergraduate and graduate students. the pi will continuously add course content based on his research expertise in materials chemistry and customize the topics to meet the research needs of the enrolled students. moreover, the pi plans to organize mini-workshops on mathematica and wolframalpha in the chemistry department at wayne state university for both undergraduate and graduate students, offered twice a year, as an endeavor to mitigate the students' common math anxiety in the learning of science courses. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: EF: Collaborative Research: MTM 2: Marine Invertebrate Microbiome Assembly, Diversification, and Coevolution

Awardee: University of Alabama Tuscaloosa

Amount: \$505,300.00

Abstract: microbes associated with marine invertebrates are of broad interest for establishing the rules of life for host-microbe associations. although some marine invertebrates host only one or two types of microbes, others host thousands of different kinds of microbes. the project goal is to understand how and why particular microbes are hosted by invertebrates; whether the **diversity** of these microorganisms is related to the **diversity** of their hosts; and how these associations change over evolutionary time. the investigators are training graduate, undergraduate, and high school students how to assess microbiome **diversity**; how to use novel software to search, categorize, and compile data from dna sequence archives; and how to identify and classify marine invertebrates. they are integrating graduate students and undergraduate students in the development of a high-school-based program to mentor students in the assessment of marine invertebrate **bio-diversity**, training the next generation of scientists in invertebrate biology, host-microbe ecology, and evolutionary data analyses. in addition, research scientists are being trained to use novel data mining and compilation software to address unexplored questions in host-microbe evolution. this project is investigating three ecological and evolutionary processes that structure the **bio-diversity** of microbiomes: assembly, diversification, and coevolution. while previous studies have focused on the host-specificity of microbiomes, the project shifts the perspective from host evolution to microbial evolution. the project is developing models of host-symbiont interactions that function across multiple spatial, temporal, and taxonomic scales. by incorporating theories from evolutionary ecology and metacommunity ecology, the investigators are assessing the relative importance of environmental filtering, host-associated selection pressures,

spatial connectivity, microbial competition, cospeciation, and host switching on the assembly of microbiomes. through the use of phylogenetic comparative methods, the project is testing whether different clades of symbionts and clades of hosts respond to these forces differently. the investigators are examining how microbiomes both impact and respond to the process of host speciation in sympatry and allopatry. to accomplish these goals, novel software and evolutionary models are being developed to support large-scale analyses of microbial diversification and colonization of eukaryotic hosts. these models are being experimentally tested by using a replicated series of settlement structures to examine the assembly of sessile marine invertebrate communities and the assembly of their associated microbiomes. in addition, marine sponges are being used as model organisms to contrast allopatric and sympatric microbiome divergence over evolutionary time. these investigations are enhancing our broader understanding of the roles of microbiomes in sustaining bio\*\*diversity\*\*. this project is funded by the understanding the rules of life: microbiome theory and mechanisms program, administered as part of nsf's ten big ideas through the division of emerging frontiers in the directorate for biological sciences. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Belmont Forum Collaborative Research: Abandonment and rebound: Societal views on landscape- and land-use change and their impacts on water and soils (ABRESO)

Awardee: University of New Hampshire

Amount: \$504,124.00

Abstract: this award provides support to u.s. researchers participating in a project competitively selected by a 9-country initiative on global change research through the belmont forum. the belmont forum is a consortium of research funding organizations representing over 55 countries focused on support for transdisciplinary approaches to global environmental change challenges and

opportunities. it aims to accelerate delivery of the international research most urgently needed to remove critical barriers to sustainability by aligning and mobilizing international resources. each partner country provides funding for their researchers within a consortium to alleviate the need for funds to cross international borders. this approach facilitates effective leveraging of national resources to support excellent research on topics of global relevance best tackled through a multinational approach, recognizing that global challenges need global solutions. this award provides support for the u.s. researchers to cooperate in consortia that consist of partners from at least three of the participating countries. the research teams will work to identify sustainable pathways to help alleviate the increasing and unprecedented pressure on the natural resources that interact to provide sustainable life support systems and essential benefits to societies such as food production and water quality and quantity. the impacts of changes in land management and urbanization will be evaluated to develop sustainable soils and groundwater management options that will help create and maintain sustainable terrestrial ecosystems. the project seeks to develop a global transdisciplinary platform for understanding the impacts of land abandonment on sustainability of soil and water resources. land abandonment and subsequent land use or land cover change can have profound implications for water resources, as the changing fabric of the critical zone dictates changes in infiltration, runoff, and the delivery of sediment and nitrogen to groundwater and surface waters. the project team will describe social and natural forcing functions that drive land abandonment and subsequent land use change; and quantify impacts on water quality due to this abandonment. the team will also identify gaps in understanding of the impacts and those perceived by stakeholders so that land use change can be better understood and modeled. the team will use this information to develop a modeling framework to assess sustainability of various land use and land abandonment scenarios in the context of the intergovernmental science-policy platform on bio\*\*diversity\*\* and ecosystem services. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: CAREER: New Platforms for Topology, Correlation, and Superconductivity in Quantum Materials

Awardee: University of Florida

Amount: \$504,022.00

Abstract: nontechnical summary this career award supports theoretical research and education on the interplay between strongly correlated quantum materials and topological phases of matter. strongly correlated quantum materials are solids in which the electrons behave collectively rather than an individual particles, while topological phases exhibit behavior that is insensitive to noise, defects, and impurities. over the past decades, driven by these two topics, condensed-matter physics has witnessed great progress, with examples ranging from high-temperature superconductors to topological insulators and topological superconductors. these advances not only deepened our understanding of the quantum physics of many-body systems but also hold enormous potential for revolutionary applications, from commercial mri machines and lossless power transmission to quantum computers that are no longer a futuristic concept. while historically

the two areas of research have, in large part, developed separately, in recently years it has become increasingly clear that their synergy reveals even richer novel phenomena and greater potential for applications. one prominent example is the so-called moire flat-band materials, including the recently discovered magic-angle twisted bilayer graphene superconductor. when two layers of graphene are twisted relative to each other and the electron density varied, the system exhibits a variety of topological phases and unconventional superconducting phases. while potential applications abound, the fundamental mechanism for forming these phases is still under intensive investigation. these developments present an exciting opportunity for breakthroughs at the intersection of topology and correlation effects. the pi will pursue the research goal in multiple directions. the pi will develop the ideas needed for a new topological quantum-computing platform based on the notion of higher-order topological phases, which seem featureless in the bulk and on the edge but host nontrivial states on the corners. the pi will uncover various kinds of topological superconducting phases in topological semimetals, which form an ideal playground for examining topology and interaction effects. to properly address the role of strong correlations, the pi will develop new theoretical and numerical approaches for quantum many-body systems that are not captured by perturbation theory and apply these approaches to topological systems, including moire flat bands. the closely related research topics addressed in this project will advance the forefronts of topological phases and their applications. an integral component of this project is an education plan at high-school, undergraduate and graduate levels, with a specific emphasis on enhancing inclusion and **\*\*diversity\*\*** in academia and the stem workforce. the pi will participate in existing programs at the university of florida to reach out to high school students through lectures and direct mentorship on summer research projects. the pi will host a series of seminars in the physics department that focuses on career development within and outside academia. via adapting and developing graduate-level courses, the pi will fill a gap in the training of junior condensed-matter physicists by bridging traditional topics and modern aspects such as topological phases. by integrating outreach and education into the research plan, this work will provide young citizens of

diverse backgrounds with unique learning and research experiences at the forefront of quantum physics and its potential applications, ensuring the success of the fundamental "quantum leap" identified by nsf as one of the "10 big ideas for future investment".      technical summary      this project focuses on the intersection between topological phases of matter, in particular topological superconductivity, and strongly correlated systems. in the first part of the project, the pi will establish a new classifying framework for higher-order topological phases based on characterization of topological defects in topological insulators and topological ordered states. the pi will demonstrate the potential application of higher-order topological superconductivity as a new platform for braiding non-abelian anyons. the second part focuses on demonstrating interacting topological semimetals as natural hosts of novel topological phases, including higher-order topological superconductivity and ultra-nodal topological superconductors with bogoliubov fermi surfaces. the final part is devoted to a close examination of theoretical models that admit topological superconducting instabilities. these models involve low-energy fermions in the vicinity of a quantum-critical point interacting with soft bosonic modes, which induce unconventional superconducting instabilities. to further understand the strong correlation and rich phases in these models, the pi will adopt and develop quantum monte carlo methods and a sachdev-ye-kitaev-like model that is exactly solvable in a large-n limit. in broader terms, these results will connect two thriving fields of condensed matter physics: unconventional superconductivity and topological phases of matter. combining tools and ideas from both rapidly developing fields will tremendously deepen our understanding of quantum many-body physics.      the project also has three main educational components targeting students at different career stages. in collaboration with the university of florida's center for precollegiate education and training, the pi will actively engage motivated high-school students through lectures on the basics of quantum computing and through individual research projects. with an emphasis on enhancing inclusion and **\*\*diversity\*\*** in academia and the stem workforce, the education plan includes a series of seminars focused on career development for physics majors and physics graduate students. through a long-term plan of

special-topic and regular graduate courses, the pi will develop a new pedagogical framework for quantum many-body physics that naturally incorporates perturbative, non-perturbative, and topological aspects of these systems, which better suits modern research activities in condensed-matter physics. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: CAREER: Impact of Pesticide and Antibiotic Cocktails on Nitrogen Removal Processes in Treatment Wetlands

Awardee: University of Kentucky Research Foundation

Amount: \$501,479.00

Abstract: nitrate is the most commonly observed chemical contaminant of ground and surface water in the world. this prevalence leads to nitrate being the major cause for drinking water impairment. common use pesticides and antibiotics have also become ubiquitous in waterways worldwide, particularly in agricultural settings. while these chemicals are important for agricultural productivity, their release to the environment has resulted in significant impacts to agroecosystem food webs and human health, including bee colony disruptions, human reproductive and development disruption, and the spread of antibiotic resistance. treatment wetland systems have the potential to be a cost-effective alternative to prevent the release of these chemicals and other emerging contaminants to the environment. however, there is a lack of understanding whether treatment wetlands can remove both nitrate and contaminant mixtures that exist in runoff; a critical knowledge gap that prevents more widespread adoption of this technology. the goal of this project is to develop science-based guidance for the use of treatment wetlands to remove contaminant mixtures and nitrate to improve water quality. this goal will be achieved by evaluating the influence of specific contaminants on wetland treatment processes using state-of-the-science tracers and automated

sensing technology. successful completion of this project may lead to cost-effective treatment alternatives for contaminants to protect human and ecological health in low income, rural communities. these results will be used to develop innovative community water quality education programs both locally and remotely. additional engagement of community members will advance scientific literacy and **\*\*diversity\*\*** through hands-on engineering experiences for underrepresented groups in stem. these groups are often among those most impacted by degraded water quality and, as a result, have the greatest potential ability to benefit from these efforts. the twin goals of this career project are to improve understanding of how antibiotics and pesticides impact nitrate removal in wetlands while engaging communities through an innovative citizen science and education platform to advance science literacy and stem workforce development. the following specific objectives are designed to achieve these goals: i) identify water quality parameters that impact nutrient removal efficacy through the use of  $^{15}\text{N}$  isotopic enrichment studies in land-based and floating treatment wetland systems; ii) create a toolkit for identifying ideal placement and sizing of wetlands using three-dimensional multiparameter in-situ sensor technologies; iii) train future practitioners through mentorship and the development of pre-k and high school curricula to deliver hands-on ecological systems education; and iv) provide citizen science opportunities and water quality training virtually and at field locations to engage affected rural communities. field and laboratory scale experimental approaches will bridge gaps between observation and kinetic modeling from microcosm and mesocosm experiments with field-scale monitoring and modeling. successful completion of this research will advance knowledge by elucidating mechanisms controlling nitrogen removal and transformation in two distinct wetland treatment systems. knowledge will also be advanced through understanding how contaminants of emerging concern impact microbially mediated denitrification in wetlands. further benefits result from improved protection of downstream water quality and reservoir resilience by evaluating the influence of specific contaminants of emerging concern on wetland ecosystem services. these results have potential to benefit society by accelerating the development of treatment wetland design and

management based on science-based observation to enhance treatment options for water in agricultural and other settings. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: CAREER: Information-Theoretic Approach to Turbulence: Causality, Modeling & Control

Awardee: Massachusetts Institute of Technology

Amount: \$500,000.00

Abstract: many flows of engineering interest are dominated by the presence of turbulence, which is the chaotic and multiscale motion of fluids. to date, real-world turbulence limits our ability to fully understand, model, and control complex systems. the lack of a rigorous framework to evaluate cause-and-effect interactions in turbulence is a cross-cutting concept at the core of discovery. the goal of the present proposal is to advance the field of turbulence research by reformulating the problems of causality, modeling, and control using information theory or the science of message communication. in this new framework, turbulence is envisioned as a sequence of bits, and its dynamics is characterized by the transfer of bits among flow variables. the theoretical foundations of this project will provide a new perspective to tackle problems in turbulence research ranging from aircraft aerodynamics to geophysical and planetary flows. the project will also leverage transformative programs to promote **\*\*diversity\*\*** and inclusion in engineering, including the participation in annual summer research programs and undergraduate research opportunities to engage women and underrepresented minorities. the goal of this project is to formulate the problems of causality, modeling, and control for turbulent flows using information theory. the central quantity of the formulation is the shannon entropy, which measures the amount of information in the states of the system. within this framework, causality in a turbulent flow can be quantified by the information flux among the variables of interest. reduced-order modeling is posed as a problem on

the conservation of information, in which models aim at preserving the maximum amount of information from the original system. similarly, control theory can be cast in information-theoretic terms by envisioning the tandem sensor-actuator as a device reducing the unknown information of the state to be controlled. this new formulation will be exploited to advance three outstanding problems in turbulent flows: (i) causality of the energy transfer in the turbulent cascade, (ii) subgrid-scale modeling for large-eddy simulation, and (iii) suppression of turbulent separation bubbles with active flow control. the cases of study range from canonical flat plate turbulence to complex flows such as realistic aircraft configurations. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: SHF: Small: Transforming Computer Architecture Evaluation with Statistical Model Checking

Awardee: Duke University

Amount: \$500,000.00

Abstract: this project is developing a statistically rigorous framework for the experimental evaluation of computer processors. the evaluation of a new processor design involves many experiments, in which the processor is simulated in different hardware configurations and with different software running on it. the current state of the art is to perform some number of these experiments and present the results, but this methodology provides no statistical guarantees; there is no bound on the probability that subsequent experiments would show very different results. this project is adapting and enhancing a rigorous statistical technique, called statistical model checking (smc), that is used in other fields that have required stronger guarantees, like cyber-physical systems (e.g., implanted medical devices). with the newly enhanced smc that this project is developing, it is possible to not only provide statistical guarantees, but it is also possible to evaluate system properties that are not analyzable with current methodologies (e.g., security hyper-properties that

depend on the differences between multiple experiments). enhancements to smc are necessary to accommodate computer architecture research and to enable, for the first time, rigorous analysis of important issues, like the impact of very rare events and the processor's behavior in worst-case scenarios. the project's infrastructure will be made publicly available, so computer architects in academia and industry can benefit from it, with the ultimate result being better processor designs in which architects and society can be more confident. this project involves undergraduate research assistants through duke's data+ and code+ programs, two well-established university-wide summer outreach programs with exceptional **diversity**. the project's research is also incorporated into a new cross-listed (ece and compsci) class in experimental evaluation of computer systems. the pi and co-pi will develop and present a tutorial on smc for computer architects at a major computer architecture conference. the project's results and framework will be transferred to industry via the extensive industry contacts of the pi and co-pi. this project pioneers the use of statistical model checking (smc) in computer architecture, thus enabling architects to reason about their experimental results with statistical rigor. this project provides architects with a novel framework for performing experimental evaluations. part of the development of the framework involves the development of expressive properties and hyper-properties that allow architects to evaluate conditions and situations they do not currently consider. this project uses smc to mitigate the longstanding problem of how to evaluate the impact of rare events, through a new event injection methodology. this project also uses smc and machine learning to provide the first statistically rigorous scheme for identifying the worst-case situation when using a mechanism (e.g., power management, computational sprinting). this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Preparing the Next Generation of Environmental Scientists through Research-based Coursework and Community Internships

Awardee: University of Puerto Rico-Rio Piedras

Amount: \$500,000.00

Abstract: there is a critical need for a more robust environmental workforce in puerto rico that mirrors similar demands across the united states in multiple sectors, including energy generation, food cultivation, and environmental protection. additionally, a larger cohort of well-prepared professionals could positively impact the island's future ability to respond to unexpected environmental catastrophes including increased frequency and intensity of hurricanes, flooding, coastal erosion, coral reef mortality, and reduced bio\*\*diversity\*\*. to address this opportunity, this project - with support from the improving undergraduate stem education: hispanic-serving institutions (hsi program) - aims to provide experiences that will engage undergraduate students in the study of environmental science and lead to an expansion of this critical workforce. in particular, the project targets students during their first two years as undergraduates, which are known to be crucial in fostering positive student perceptions towards the discipline and successful academic outcomes. incoming freshman will participate in a summer research project that will provide hands-on experiences to build excitement and contribute to a more thorough understanding of future careers. throughout their course of study, students will engage in four content-rich courses with substantial field work components and will have opportunities to participate in community-facing internships. the proposed courses and experiences will be embedded in the regular environmental science undergraduate curriculum, thereby enriching the current degree requirements while providing innovative academic strategies for students through practical experiences created with the purpose of improving student retention. the proposed project has three main objectives. first is to create annual el verde field station (evfs) summer research experiences to attract 30 incoming freshmen. second is to design an environmental analysis training curriculum to improve technical skills. and third is to develop a paid internship program to bring environmental science undergraduates and local employers together. a longitudinal, quasi-experimental study will be employed to evaluate the hypothesis that the treatment sequence in the program will contribute to improving environmental

science student retention, enhancing content knowledge, and expanding students' technical skills. quantitative and qualitative approaches will provide evidence-based data to determine if there is an individual and/or additive effect of the project components on participant students' attitudes and persistence in environmental science undergraduate studies. expected products include student-generated environmental science research videos demonstrating techniques and documenting their experiences in the program, conference presentations, journal publications, and meetings and workshops at university of puerto rico-rio piedras with high school teachers and counselors to share project outcomes. furthermore, curricula, educational resources, and research instruments will be available for sharing with teachers and researchers. the hsi program aims to enhance undergraduate stem education, broaden participation in stem, and build capacity at hsis. achieving these aims, given the diverse nature and context of the hsis, requires innovative approaches that incentivize institutional and community transformation and promote fundamental research (i) on engaged student learning, (ii) about what it takes to diversify and increase participation in stem effectively, and (iii) that improves our understanding of how to build institutional capacity at hsis. projects supported by the hsi program will also draw from these approaches to generate new knowledge on how to achieve these aims. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: CNS Core: Small: Offline Inference for Ultra-Efficient Memory Management

Awardee: University of California-Los Angeles

Amount: \$500,000.00

Abstract: machine learning (ml) has made its way into systems of various kinds, helping them make informed decisions at critical points. a typical approach to ml-for-systems is to perform inference online by querying a model with runtime data. online inference incurs non-trivial overheads,

imposing a tight restriction on model size and complexity. in fact, systems that involve ml in their decision making often use very simple models (e.g., linear models) with inferior accuracy. this project develops a transformative approach to ml-for-systems - instead of doing online inference, this project advocates to train models that can predict runtime properties directly from program source code. as such, inference can be done offline and their results can be encoded and efficiently looked up during execution. given that inference no longer contributes to run time, the proposed approach removes the above-discussed restrictions, enabling systems to employ state-of-the-art model architectures. this project further applies offline inference to memory management tasks that are critical to cloud applications. modern society relies on services provided by large-scale systems. improving the throughput and efficiency of such systems improves the service-level efficiency and scalability that human can experience in their lives. replacing complicated and heuristics-driven decision making in today's memory management systems with learning has a potential to dramatically reduce the cost of allocation and deallocation, which is a significant component in an application's execution. traditionally, inference is performed online, restricting what models to use and how high the accuracy can reach. this project develops techniques that make ml a more appealing approach by removing these restrictions. the techniques proposed span runtime system and ml. this interdisciplinary nature produces research that has impact in both areas. the project also makes efforts in education and **\*\*diversity\*\*** by incorporating research into courses and recruiting researchers from underrepresented groups. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

-----

Title: CCF: Small: Real-Number Function Encoding Driven Error Resilient Signal Processing and Control: Application to Nonlinear Systems from Adaptive Filters to DNNs

Awardee: Georgia Tech Research Corporation

Amount: \$500,000.00

Abstract: technology scaling, device integration and high circuit speeds have increased the risk of errors in digital processors running computing and control applications. such errors can jeopardize the operational safety of autonomous systems employing embedded processors in the field, causing severe loss of performance, accidents, or damage to life and property. to put this in perspective, applications such as self-driving cars and drones demand tera-ops of computation throughput and yet must perform with exacting levels of reliability and safety. the latter reliability and safety demands must be met with minimal degrees of hardware and software redundancy without negatively impacting dependability, power consumption, payload, form factor and cost considerations that are critical for commercial success. to alleviate relevant safety threats, this project aims to deploy low-cost and efficient methods for detecting and mitigating the effects of monitored errors in real time and in the field as effectively and rapidly as possible. this will enable a paradigm shift in the way failure-tolerance technologies are applied to autonomous systems while maintaining their reliability, affordability and cost. the project integrates research with education involving development of educational infrastructure for teaching and laboratory work, incorporation of **\*\*diversity\*\*** in student participation, exchanges with industry, technology transfer and engagement with undergraduate and high-school students, all with the goal of producing highly qualified trained engineers for the workplace of the future. today, implementing failure tolerance for nonlinear signal-processing and control algorithms is dependent on some form of computation duplication. the algorithm-based fault-tolerance techniques of the past were designed mostly for linear computations and are not directly applicable to error control in nonlinear computations of modern autonomous systems. to resolve this, the project is built around the concept of algorithmic checks that encode nonlinear computations with linearized or nonlinear checking mechanisms. the checks are created using analytical methods for weakly nonlinear systems or by machine-learning algorithms for generic nonlinear systems and enable real-time error detection in switched capacitor circuits, nonlinear digital filters, adaptive state-estimation filters, nonlinear control algorithms and

deep neural networks. error correction is performed via state restoration in which the system state after error detection is restored to a prior fault-free system state or by using probabilistic error-compensation techniques. the core techniques can be applied to different aspects of the core computations performed in embedded computing infrastructure for autonomous systems, namely perception, intelligence, decision-making and control to make them error-resilient and trustworthy. the underlying science is enabling the design of entirely new classes of self-checking reliable autonomous systems that are beyond the scope of the current state of the art. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: CNS Core: Small: Principled Methodologies and Systems Support for Automated Cost-Effective Service Blending in the Emerging Public Cloud

Awardee: Pennsylvania State Univ University Park

Amount: \$500,000.00

Abstract: a growing number of individuals and organizations rely on public cloud providers for their information technology (it) needs. many of these cloud users are budget-constrained and, therefore, interested in ways to reduce their cloud bills while still meeting their applications' performance needs. cloud providers offer myriad service types (spanning infrastructure-, platform-, and software-as-a-service and **\*\*diversity\*\*** within each of these) and blending these can offer significant cost savings to users over prevalent techniques that tend to be limited to a small number of service types. however, getting such blending right is non-trivial and may itself pose significant effort and cost. this project aims to help users overcome such hurdles by significantly automating the process of cost-effectively blending and sizing cloud services. in particular, this automation will be realized via a cloud cost optimizing compiler called coco. a framework for application code annotation will allow users to convey blending-related hints based on their domain expertise. coco will require

fundamentally novel optimization techniques and heuristics to transform user code into its cloud-ready form which will be cost-effective while meeting performance requirements. finally, a runtime system for continual adaptation to dynamic workload changes will also be developed. all of these ideas will be prototyped on state of the art public cloud platforms and open-sourced. this project has the potential to significantly simplify the task of migrating user applications to the public cloud with attendant cost savings. perhaps more importantly, the transformed code is expected to incur lower recurring cloud bills owing to careful blending and sizing of cloud service types that adapts to dynamic conditions. these innovations are likely to be especially useful to small/medium-sized users for whom cloud migration can pose significant technical and cost hurdles. the educational and outreach components of the project will create awareness of such cost savings offered by service blending and, in combination with our open-source prototypes, will help spur further innovations on related themes within the cloud computing research community. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: FET: Medium: Neuroplane: Scalable Deep Learning through Gate-tunable MoS2 Crossbars

Awardee: Northwestern University

Amount: \$500,000.00

Abstract: the increasing complexity of deep-learning systems has pushed conventional computing technologies to their limits. while the memristor is one of the prevailing technologies for deep-learning acceleration, it is only suited for classical learning layers where two operands, namely weights and inputs, are processed at a time. meanwhile, to improve the computational efficiency of deep learning for emerging applications, a variety of non-traditional layers, requiring concurrent higher-order processing of many operands, are becoming popular. for example, hypernetworks

improve their predictive robustness by simultaneously processing weights and inputs against the application context. two-electrode memristor grids cannot natively support such operations of emerging layers. addressing the unmet need, this research will develop neuroplane -- a novel deep-learning accelerator of gated memtransistor crossbars. exploiting crossbars' gate controllability, multiple operands can be processed within the same crossbar unit in neuroplane. many advanced inference architectures that can generalize beyond a typical passive crossbar will thus be possible. overall, the ultra-low-power, higher-order processing of neuroplane will harness high robustness and efficiency of emerging deep-learning layers within area/power-constrained devices such as mobile, sensor, and embedded systems. the investigators will develop fabrication methods for nanometer node gate-tunable dual-gated crossbars of mos2 memtransistors. a self-aligned fabrication method with defect passivation and process variability compensation will be created. exploiting the gate-tunability of mos2 memtransistors, a new generation of crossbar platforms with many runtime control knobs will be developed, rendering the design a high elasticity and agile computing space. for example, computing methods will be created for the gated crossbars to utilize crossbar elements for product-sum digitization, thereby preventing the critical overheads in current crossbar technologies. similarly, control-flow methods will be developed for gated crossbars to adapt their inference paths depending on the input characteristics by dynamically deactivating input/output neurons to conserve processing energy. a coherent collection of software and hardware-based correction techniques is proposed to minimize the impact of process variability. unlike the current schemes, by following the train-once-deploy-anywhere tenet, the proposed crossbar correction methods can scale to millions of deployments without considerable overhead. an annual workshop will be conducted at local high schools with substantial ethnic and gender **\*\*diversity\*\*** to mentor underrepresented students. undergraduate research projects will be sponsored using paid summer internships and university-level programs such as summer undergraduate fellowship. an inter-university senior-design mentoring program will be created for students among participating institutions. this award reflects nsf's statutory mission and has been

deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: CAREER: Modernizing Risk Assessment Through Systematic Integration of Probabilistic Risk Assessment (PRA) and Prognostics and Health Management (PHM)

Awardee: University of Maryland, College Park

Amount: \$500,000.00

Abstract: safe, reliable, affordable energy is intricately connected to broad advances in health, science, prosperity, and our national defense. engineering risk assessment is an essential tool used in designing the regulations, codes, and standards that enhance energy system safety and resilience without imposing unreasonable regulatory burden. advancing the science behind

risk-informed regulation is essential as systems become more complex and new challenges emerge. this faculty early career development (career) project investigates how principles from two domains of reliability engineering can be systematically integrated to advance this science. this research that probabilistic risk assessment (pra) and prognostics and health management (phm) have complementary characteristics that can offset their individual weaknesses. the research will establish and validate a conceptual framework along with mathematical and computational methods to systematically integrate pra and phm methods, data, and models. direct engagement with interdisciplinary stakeholders from nuclear power plant and hydrogen transportation infrastructure applications will facilitate both validation and adoption of the new methods. the results will provide new knowledge about the range of data and models that can be used in regulatory design and decision making. integrated educational initiatives include design of the first public museum exhibit on energy system risk assessment, enhanced reliability engineering coursework, and **\*\*diversity\*\*** and inclusion initiatives for women and underrepresented minorities in engineering. the overarching goal of this project is to establish a strong foundation of integrated research and educational activities centered on energy system risk assessment. the research focuses on transforming risk-informed regulation for energy systems through systematic integration of concepts, data and methods drawn from pra and phm and rigorous validation using both energy system case studies and expert stakeholder engagement. the educational activities enhance k-12 and public education through a new museum exhibit on energy system risk assessment that will be displayed in the nation's only nuclear history and science museum and that will also be made available to a broad network of affiliated museums. graduate coursework in reliability engineering will be enhanced through development of new active learning exercises based on this research. the research draws upon engineering techniques of pra, which provides a comprehensive quantitative approach for synthesizing data, scenarios, and probability models to assess risk under uncertainty for complex engineering systems; and phm, which provides powerful algorithms for using sensor data and failure models to understand and predict health of components. to date, there has been little work at the

intersection of pra and phm. unlike previous approaches which seek to make pra more dynamic or to extend phm to more complicated components within their current architectures, this research seeks to deconstruct pra and phm and engineer a new approach which leverages the benefits of both approaches. the research starts by defining the conceptual framework and then defining mathematical and computational structures. the candidate structures will be compared and validated using energy system case studies and stakeholder-based validation. nuclear power plants and hydrogen fueling stations are used as testbeds to ensure that the results are generalizable beyond a single energy system or regulatory process. the research has broader societal impact by creating new knowledge and methods that will impact the design of regulations for nuclear power plants, hydrogen infrastructure, pipelines, and other energy systems and critical infrastructures. the integrated educational activities broaden k-12, graduate student, and public understanding of the science behind energy system safety. broader participation of women and underrepresented minorities in engineering will be encouraged via the enhancement of graduate student recruitment and mentoring activities. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: (Radio)Fluorination and Other Nucleophilic Functionalizations Enabled by Photocatalytic Radical-Polar Crossover

Awardee: University of California-Los Angeles

Amount: \$500,000.00

Abstract: with the support of the chemical synthesis (syn) program in the division of chemistry, professor abigail doyle of university of california, los angeles is developing new chemical reactions that will enable the synthesis of organofluorine compounds; namely those that contain a c-f bond. such bond constructions are in high demand as c-f bonds are found in next-generation medicines,

agrochemicals, and biomedical imaging agents. the chemical reactions under development here use a catalyst that can harness the energy in visible light to generate a high-energy reactive intermediate, a carbocation, that is most often only accessible under harsh (thermal or strongly acidic or lewis-acidic) conditions. because the strategy being pursued by professor doyle and her students accesses this intermediate under the mild conditions associated with visible light irradiation, reactions are being developed that generate chemical structures that were previously challenging to access, starting from abundant and inexpensive reagents. the researchers will use a variety of tools to help them understand how the reactions work at the molecular level such that this knowledge can be used to discover new processes and design improved reactions. students conducting these research activities will have the opportunity to develop a broad skill set, both scientific in nature and with respect to communication, mentorship, leadership, and also with respect to embracing and building **\*\*diversity\*\***, equity, inclusion and belonging, that will help them become leaders in their independent careers. broader impacts of this work also include the development of activities directed at recruitment and retention of students from underrepresented groups to science, technology, engineering, and mathematics (stem). for example, the program includes the development of undergraduate teaching material to highlight scientific contributions from researchers of diverse backgrounds, experiences and perspectives and the design of workshops for entering graduate students on topics such as citation bias, conflict management, and micro-aggression.

carbocations are reactive intermediates in a broad range of synthetic transformations because they undergo reaction with abundant and stable nucleophiles like water, alcohols, halides, amines, and olefins. nevertheless, the generation of carbocation intermediates typically requires harsh reaction conditions and requires use of pre-oxidized precursors such as alkyl halides. these limitations preclude applications in more complex settings, such as in the synthesis of bioactive compounds or radiolabelling, and access to desirable products. this program seeks to address these challenges by using a photocatalyst and light to convert abundant and stable  $c(sp^3)OH$ ,  $RNH_2$  and  $RH$  precursors to radicals and then to carbocations (a so-called radical-polar

crossover). a focus of these efforts will be to use fluoride to trap the carbocation intermediates in order to generate organofluorine products that are useful in the pharmaceutical and agrochemical industries. mechanistic studies will accompany these synthetic efforts and the most efficient strategies will also be adapted for the synthesis of 18-fluorine-radiolabelled small molecules for use in positron emission tomography (pet), an important diagnostic tool for detecting disease. this research will provide a rigorous and multi-disciplinary training environment for a diverse group of graduate and undergraduate students and postdoctoral fellows. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Side-Chain Driven Assembly of Polymer Semiconductors

Awardee: Georgia Tech Research Corporation

Amount: \$500,000.00

Abstract: with the support of the macromolecular, supramolecular and nanochemistry program in the division of chemistry, prof. natalie stingelin and dr. anna m. österholm of georgia institute of technology are studying fundamental processes that underlie the assembly of polymer semiconductors. the local arrangements of these long chain macromolecules dictate important photophysical, electronic and electrochemical processes in this broad class of materials. all of these processes are important in a range of optoelectronic device platforms, such as led (light-emitted) screens, wearable electronics, and even bioelectronics. in this research, semiconducting polymers will be prepared in which the main polymer backbone is decorated with side-chains of different lengths, densities, and polarity. optoelectronic properties will then be investigated to gain further understanding on how they depend on side-chain arrangement and subsequent backbone ordering. as opposed to conventional synthetic approaches, this research will use electricity and blending with surfactants to manipulate and control side-chain assembly. relevant physical processes associated with polymer dynamics will be investigated using a plethora of sophisticated experimental tools. they include linear and vibrational spectroscopies, thermal analysis, and electrochemical measurements that allow for rapid evaluation of polymer assembly motifs. this project will create a highly multidisciplinary and diverse research and education environment for students where they will be exposed to academic and industrial perspectives, national laboratories, as well as national and international collaborators. the research team will also partner with the georgia tech's center for organic photonics and electronics, the georgia tech polymer network, and groups such as women in

materials science and engineering (wimse) and women in chemistry (wic) to develop a set of **\*\*diversity\*\***-supported programs focusing on preparing underrepresented minorities for faculty positions. this research aims to provide fundamental insights of the physics underlying the assembly of polymer semiconductors, focusing on answering the question of what role side-chain design plays in dictating backbone order/disorder. particular emphasis is placed on the use of electrochemical and physicochemical approaches to control the side-chain interactions and subsequent backbone order in various polydioxothiophenes to deliver an assembly framework that exploits the sidechain arrangement for dictating backbone ordering. side-chain motifs that promote supramolecular assembly in neat polymer semiconductor systems into solid-state structures with little backbone distortion will first be identified with a strong emphasis on chemical structure, side-chain branching point location, and side-chain density. electrochemical doping will then be utilized to investigate changes in polymer assemblies and how they influence both redox and charge transport properties. lastly, small molecule additives will be blended with a polymer semiconductor to examine their effect on backbone conformation. this research will address fundamental questions in the field of conjugated polymers through extrinsic approaches rather than the synthetic ones. if successful, the proposed work will have a major impact on the semiconducting polymer field, particularly optoelectronic device platforms, such as organic light-emitting diodes, organic photovoltaics, organic field-effect transistors, as well as emerging technologies for bioelectronics and neuromorphic sensing. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Giant Polymer Brushes: How Fluid-Like Hyaluronan Brushes Minimize Biofilm Adhesion

Awardee: Georgia Tech Research Corporation

Amount: \$500,000.00

Abstract: non-technical abstract it is surprising how much can be accomplished by changing the properties of a surface. when made hydrophobic, a surface repels water and can, for example, protect paper or wood from moisture intrusion and damage. when made reactive to a specific gas or biomolecule, it can become an ultra-sensitive detector, for example a biosensor for coronavirus particles. one very successful way to control surface properties, so as to create designer materials like those described above, is to anchor polymers to the surface at such a high density that they align and stretch away from the surface because of crowding by their neighbors. this configuration is

known as a polymer brush. polymer brushes have been used in a stunning variety of practical applications. this grant has a twofold scientific purpose. the first purpose is to leverage nature's molecular machines to produce polymer brushes by growing molecules directly from the surface. amazingly, this new technology enables the production of polymer brush layers nearly one hundred times thicker than the those achievable with conventional techniques. this presents exciting new properties for the strategic design of materials. the second purpose is to address an important problem that plagues mankind: the formation of biofilms ? that is communities of recalcitrant bacteria entrenched and protected in a mucous-like goo of their own making. polymer brushes are a popular strategy to delay biofilm attachment but ultimately, they still fail. motivated by promising preliminary results, the project explores in this grant whether the giant molecular-machine generated brush and its corresponding fluid-like interface can lead to a surface that the bacteria are unable to tether to ? a new strategy only recently introduced in other contexts. to ensure that any bacteria which still manage to adhere are quickly eliminated, the researchers will embed antimicrobials within the large volume of the brush. together, these measures will result in the maturation of an exciting new polymer brush technology addressing the age-old problem of bacterial infection and contamination of man-made materials. in outreach and education, the curtis lab will publish a series of short playful cartoon videos about the science, biomaterials, and applications of this interdisciplinary project. the videos will be shared on a you tube channel and disseminated widely. topics will include anti-microbial materials, biofilms, polymer brushes, and molecular machines for making polymers.

technical abstract polymer brushes are an important tool for engineering interfaces in a variety of applications such as drug delivery, implants, catalysis, and anti-microbial materials. this grant will focus on pinpointing the origin and extent of the anti-fouling properties of a non-traditional, ultra-thick polymer brush recently established in the curtis lab. fabricated by surfaces coated with hyaluronan synthase, the enzyme-derived brushes are the thickest ever created by almost two orders of magnitude. preliminary results demonstrate that these hyaluronan brushes repel bacteria and prevent biofilm adhesion for up to a week, performing an order of magnitude better than hyaluronan

films, which are recognized as having superior anti-fouling properties. the curtis lab will test the hypothesis that the superior performance of these brushes arises from their fluid-like interface, similar to other recent very successful materials introduced for anti-biofilm applications. in addition, they will optimize the anti-fouling performance of the brushes with systematic studies of its dependence on brush grafting density and molecular weight. lastly, to maximize the anti-biofilm properties of the brush, they will immobilize biocides throughout the material to create a multi-functional biointerface with optimal anti-microbial performance. more broadly, this research will contribute to the continued development of a new class of polymer brush, which is expected to find broader applications in materials science. in outreach and education, the curtis lab will publish a series of short playful cartoon videos about the science, biomaterials, and applications of this project. the videos will be shared on a you tube channel and disseminated widely. topics will include anti-fouling materials, biofilms, polymer brushes, etc. additionally, dr. curtis will continue her efforts to increase **\*\*diversity\*\*** in stem by using the period of this grant to establish contacts and build lasting relationships with faculty, advisors, and students at historically black colleges and universities. these activities have the primary goals of (1) building effective relationships to help improve recruitment and retention of minority students and (2) learning through conversations how to enhance the climate at georgia tech to make it more welcoming and supportive for students of color. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Fundamental Studies on Spider Egg Case Silk Biomaterials and their Mimics

Awardee: Arizona State University

Amount: \$500,000.00

Abstract: non-technical summary    silk is a fascinating, naturally occurring biomaterial that has had a large impact on human civilization. although silkworm silk is the most investigated biomaterial, in part because of wide availability, the **\*\*diversity\*\*** of spider silks available can lead to new generations of hitherto unexplored biomaterials. spiders produce many different forms of silk including ones used to construct egg cases. spider egg case silk proteins and biopolymer fibers have scarcely been studied, compared to spider dragline silk (commonly used to as the scaffolding of spider webs) and silkworm silk. yet, its mechanical properties (i.e., toughness) and conserved and repetitive gene sequence have been studied and shown to be significantly different from other spider silks. the molecular structure- and mechanical-function relationship in spider egg case silks and biomaterial composites with nanoparticles will allow for the development of new bionanomaterials with predictably tunable optical, mechanical and thermal properties. this biomaterials research brings together aspects of biochemistry, biomaterials and bioengineering, which requires a diverse scientific team, including physicists, chemists, biochemists and bioengineers from arizona state university (asu) and collaborations with argonne national laboratory (anl). this multi-institutional and multi-disciplinary research will expose graduate, undergraduate and high school students to modern transdisciplinary research and modern communication and teamwork tools for building and maintaining research across multiple labs and institutes.

technical summary    spiders produce different forms of silk proteins or spidroins, of which, tubuliform and aciniform silk is used to construct egg cases. the mechanical properties (i.e., toughness) and conserved and repetitive gene sequence are known for many spider's egg case silk proteins and shown to be significantly different from other proteins used to make the more commonly studied dragline spider silks. the proposed research team plans to explore the structure-function relationship in spider egg case silks, spider silk polypeptides derived from spider

egg case silk protein motifs, and biomaterial nanocomposites of egg case silks with nanoparticles. using recently developed methods for obtaining appreciable quantities of isotopically enriched spider egg case silks, molecular structure and dynamics will be investigated using advanced magnetic resonance techniques. besides natural spider silks, significant effort will be placed on peptide mimics derived from spider egg case proteins repetitive motifs, allowing structure-function studies, self-assembly and potentially in the long-term overcoming the bioproduction bottleneck for practical application. using both spider silk polypeptides and processed spider egg case silk, nanoparticle-silk composite biomaterials with tunable properties will be designed and generated for specific biomaterials applications. the biocompatibility of the spider silk polypeptides, their mimics and nanocomposites will be studied comprehensively in vitro and in vivo. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: NSF-BSF: Designing semiconductor-based membranes for photoelectrochemical modulation of cardiac systems

Awardee: University of Chicago

Amount: \$500,000.00

Abstract: non-technical summary finding biomaterials to replace the wires in heart pacemakers remains a challenge for society. many biomaterial approaches have been developed for pacing heart tissue without leads; the wires that connect to the tissue. existing alternative strategies have not been successful in clinical settings. in this collaborative project between nsf and the u.s.-israel binational science foundation (bsf), drs. tian and dvir propose to develop a new class of silicon (si) and silicon carbide (sic)-based nanostructured membranes for optically controlled stimulation of cardiac tissues. the semiconductor-based membranes are flexible and biocompatible, and are capable of bypassing many of the current limitations faced by traditional cardiac pacing tools. the

team will use the pulsed light illumination of the si and sic membranes to trigger the excitation of heart cells under physiological conditions. this research will provide new data that are critical for understanding and developing biomaterials-based tools to meet the needs of future cardiac therapy. the educational goals include providing learning opportunities for students in a highly interdisciplinary area. dr. tian will build on existing model programs at the university of chicago to increase **\*\*diversity\*\*** in science and engineering by offering summer research opportunities to high-school and undergraduate students. other educational activities include an international student exchange program to provide us students with unforgettable awareness and lifelong appreciation of the science and engineering research in israel. the research and education results will be disseminated broadly through peer-reviewed publications, seminars, conference presentations, and websites.

technical summary      many biomaterial approaches for leadless cardiac pacing capabilities, including those based on infrared photothermal effect, electromagnetic induction, and ultrasound-mediated energy transfer, have failed to translate clinically. therefore, new biomaterial tools and biointerfaces are still highly desired for understanding the treatment of arrhythmias and conduction disorders. drs. tian and dvir propose to develop a new class of silicon (si) and silicon carbide (sic)-based nanostructured membranes for optically controlled, non-genetic modulation of cardiac tissues. the semiconductor-based membranes are flexible and biocompatible, and are capable of bypassing many of the current limitations faced by traditional modulatory devices. when activated by pulsed light illumination, the si and sic nanostructures can trigger membrane depolarization of cardiomyocytes under physiological conditions, causing the interfaced cardiomyocytes to fire action potentials. this research will provide new data that are critical for the fundamental understanding and development of biomaterials-based tools to enable future leadless cardiac resynchronization therapy. the research activities will provide learning opportunities for students in a highly interdisciplinary area. the proposed study will also provide a unique knowledge and skill set that can open new endeavors in the semiconductor or detector industry. dr. tian will build on existing model programs at the university of chicago to increase **\*\*diversity\*\*** in science and

engineering by offering summer research opportunities to high-school and undergraduate students. through an international summer exchange program, the team will provide the us students the experience to establish unforgettable awareness and lifelong appreciation of the science and engineering research in israel. the research and education results will be disseminated broadly through peer-reviewed publications, seminars, conference presentations, and websites. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Designing Inclusive Computational Thinking Metrics to Broaden Participation in Computer Science

Awardee: Northeastern University

Amount: \$499,999.00

Abstract: broadening participation in computer science requires helping students understand how they can use computer science in ways that they see as valuable. this includes students? learning by designing their own games. the experience of game design has proven effective at helping them learn about algorithms, computational thinking, and programming in meaningful ways. tools such as scratch programming enable students to engage in such game design learning. however, interpreting and assessing students? understanding of computer science in these environments is challenging. automated approaches to assessing the products students create may have biases or may not account for diverse approaches to game design. automated assessments have the potential to provide feedback on their work to students in real time and help them learn about computer science effectively. this project seeks to understand how to create methods for automatically analyzing students? computational thinking that are equitable, inclusive, and diverse.

the work addresses three critical needs in computer science education: (1) improving computational thinking metrics to support automated assessment of computational thinking; (2)

providing students with real-time feedback that helps them monitor their progress in computational thinking and programming to build confidence in their skills; and (3) creating context-sensitive assessment and feedback tools that promote inclusivity and encourage students to learn about computer science, computational thinking, and programming. the key research question in this project is: how do we address inclusivity and **diversity** in existing metrics-based automated computational thinking assessments to help broaden participation in computer science? the project will use assessment data gathered from eighth-grade students using scratch who created games connected to science concepts. the analysis of students' products will document how students' computational thinking development, design practices, and programming routines are assessed currently. subsequent work will create metrics that are more inclusive and equitable. the project will use machine learning techniques to analyze data (e.g., to identify patterns in the students' products). the project will also use measures of self-efficacy in computer science to understand students' product design. in later phases of the project, a participatory design process will be used to redesign the metrics to enhance inclusivity in the assessment of computational thinking via game design in scratch. this project is funded through the cs for all: research and rpps program this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Computational Thinking Funds of Knowledge: A Culturally-Relevant Assessment for Early Elementary Students

Awardee: University of Massachusetts Amherst

Amount: \$499,999.00

Abstract: this award is funded in whole or in part under the american rescue plan act of 2021 (public law 117-2). it is developing equitable computational thinking (ct) assessments for historically marginalized black and hispanic students in the early grades. children and their families engage in ct

in their everyday lives, with such experiences serving as potentially powerful learning and assessment opportunities. the everyday knowledge of black and hispanic families and communities, in particular, must be interwoven with instructional and assessment opportunities, as too often they are not reflected in standard instruction and assessment. given the lack of **\*\*diversity\*\*** in computer science, uncovering the rich ct resources of black and hispanic families through research will aid in the development of culturally sustaining assessments tools (csat) for ct. this will help educators leverage what students know in order to find ways to support these underrepresented students. this knowledge will subsequently provide a foundation for development of more equitable ct assessment materials. this approach is transformative, in that it puts family and community knowledge at the heart of assessment development. it addresses concerns related to the problem of cultural bias in standardized measures of achievement. while focusing on the lived experiences of black and hispanic families in springfield, massachusetts, the team anticipates that the csat for ct will be useful for black and hispanic families in mid-sized cities similar to springfield, and will, therefore, have a broad national impact.

computational thinking funds of knowledge (ctfok) is a research project focused on the development of csat for ct for students from kindergarten to second grade. it seeks to broaden participation in computer science (cs) by explicitly focusing on the rich resources of black and hispanic families as regards their ctfok enacted through activities of daily living and by creating valid assessments that reflect that knowledge and cultural context. through classroom observations, family interviews, and teacher interviews, research in this project will focus on: identifying family and community ctfok with which children enter school; the effectiveness of the csat for measuring ct; young students? conceptual understanding of ct (grades k-2); teachers? experience on the project, especially as reflected in knowledge of and valuing of strengths-based approaches to working with black and hispanic families and students, and in integrating cs/ct concepts into these teachers? instructional practices. traditional assessments have been shown to embed cultural bias, thus perpetuating disadvantage for children of color. therefore, it is vitally important that the cs educational research community develop assessment methods that are equitable. the work is

transformative on two levels: first it centers family and community knowledge as foundational to children's prior and future knowledge; and second, it uses this information to create equitable assessment materials. this work will have a broad impact in providing the results of research to the cased community at large. this project is supported through the cs for all: research and rpps program.

this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Excellence in Research: Collaborative Research: Computational Modeling and Experimental Investigation on Multivalent Interaction at Nano-Bio Interface for 2D Materials

Awardee: Clark Atlanta University

Amount: \$499,999.00

Abstract: part 1: non-technical summary nano-materials are extremely small sized materials. nano-materials become biomaterials when they directly or indirectly interact with living things, and also when they are used as biosensors, bioimaging or therapeutic agents. understanding the interactions occurring at the interface of such nano-materials and biological molecules is very important for several potential applications. the current project will develop novel, two-dimensional (2d) nano-materials and examine their physical and chemical interactions with biomolecules. this will be accomplished by coupling computational simulations and experimental investigations. the expected outcome is that novel nano-platforms will be developed, and they will have capability to be explored for numerous promising applications in industry. successful completion of this project will offer many fascinating physicochemical properties that will generate exciting opportunities for future two-dimensional nanomaterials-based biosensing, bioimaging, and therapeutic applications. the project will provide excellent research and education opportunities for underrepresented minority undergraduate and graduate students from clark atlanta university and jackson state university. the current project will increase the skilled workforce in the important fields of computation and

emerging novel material design, with an emphasis on enhancing and promoting **diversity** from underrepresented groups.      part 2:      technical summary      the project will provide a better understanding of the nano-bio interface at the cellular and molecular levels, which is extremely important to guide the rational design of 2d material for biomedical devices. the proposed research will address essential new questions on how the heterogeneous nature of the biological system influences the dynamics of nano-bio interactions. the research and educational activities of this project include: (i) development, computational exploration, and characterization of chemically functionalized 2d materials of graphene oxide and phosphorene; (ii) elucidation of the multivalent interactions at nano-bio interfaces between 2d materials with dna/rna, proteins, and peptides; (iii) understanding how corona formation on 2d nano-material changes the biological fate, using cell viability and cellular uptake experiment; (iv) performing computational modeling to understand the interactions of 2d materials with biomolecules; and (v) engaging minority students in advanced research on emerging nano-bio technologies. the current project will provide opportunities for underrepresented minority participants to become next generation materials scientists through innovative research and education in emerging 2d material-based biotechnology research areas. the successful execution of this project may lead to the development of safe nano-materials for bio-nano technologies.      this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: FIRED UP: An immersive early field experience program to build community, support inclusivity, and foster large-scale research ideas

Awardee: University of Colorado at Boulder

Amount: \$499,997.00

Abstract: this national science foundation innovations in graduate education (ige) award to the university of colorado boulder will test the efficacy of a first-year graduate student program designed

to promote the inclusion of students from diverse identities as well as provide discipline-specific training in field methods. currently, ecology and evolutionary biology graduate programs in the us lag behind other biological disciplines in the representation of peer students (persons excluded due to ethnicity and race). this project aims to address this issue by piloting a program that aims to increase peer recruitment, create a cohort community, improve the sense of belonging among students, increase early access to expert field methods training, and expand training to address ecological questions relevant to global environmental change. challenging issues related to environmental change, such as bio\*\*diversity\*\* loss and climate change, require a diverse workforce of highly trained biologists who can collaborate across disciplines and produce solution-oriented scientific approaches. while our program is tailored to the disciplines of ecology and evolution, the basic elements of the program could be adapted to many stem disciplines and broaden the impact of this approach. the pis of this project will work to increase peer graduate student recruitment efforts through connection with multiple conferences and networks that promote student \*\*diversity\*\*. the design of the graduate education model draws on theories of human motivation and personality (self-determination theory and sources of self-efficacy) to target psychological needs that, when satisfied, foster well-being and success in graduate school: autonomy, competence, and relatedness. by providing an early immersive field experience for a cohort of students the summer before they begin graduate school, our program will work to remove the barriers that fieldwork poses to peer students interested in ecology while providing critical early-training and cohort building to increase retention and students' success. the project will take advantage of the well-established niwot ridge long-term ecological research (nwt lter) program and the mountain research station at cu boulder. evaluation of the program will focus on understanding how programmatic components support students in developing competence in the field and analytical methods, autonomy and independence as researchers, and a sense of belonging within the field. the project aims to publish and disseminate the approaches used to be accessible for a variety of stem fields in addition to the discipline-specific results in ecological science. the innovations in graduate education (ige)

program is focused on research in graduate education. the goals of ige are to pilot, test and validate innovative approaches to graduate education and to generate the knowledge required to move these approaches into the broader community. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: III:Small: Interpretable Deep Generative Models for Drug Development

Awardee: Ohio State University

Amount: \$499,995.00

Abstract: drug discovery is time-consuming and costly: it takes approximately 10-15 years and between \$500 million to \$2 billion to fully develop a new drug. molecule optimization is a critical step in drug discovery to improve desired properties of drug candidates through chemical modification. for example, in lead (molecules showing both activity and selectivity towards a given target) optimization, the chemical structures of the lead molecules can be altered to improve their selectivity and specificity. conventionally, this process is facilitated based on knowledge, intuition and experience of medicinal chemists, and is done via fragment-based screening or synthesis. such an approach is not scalable. the objective of this project is to develop a new class of artificial intelligence (ai) methods and tools to conduct in silico molecule generation. specifically, this project will focus on the following important aspects in ai-based in silico molecule optimization: 1) major scaffold retention, 2) molecule **\*\*diversity\*\***, 3) molecule synthesizability; 4) multi-property optimization; and 5) interpretability. the central hypothesis underlying the proposed research is that the increasing amount of publicly available molecule data, including molecule properties, synthesis pathways and drug-likeness, contains a wealth of information that, if properly analyzed and utilized, can provide key insights in revealing, characterizing and automating the computational molecule generation and optimization process. developing a new class of ai methods for in silico drug

molecule optimization will require the development of novel ai models and methods for in silico molecule optimization. examining designs based on new deep generative models, deep graph convolutional networks, conditional sampling approaches and reinforcement learning methods that learn from pairs of molecular graphs, and accordingly generate new molecular graphs with improved biochemical and biophysical properties, is necessary. the proposed research will also provide a holistic framework to explore prospective molecules that are sufficiently different from one another; and will investigate molecular graph search approaches and bayesian optimization methods to guide search in the latent embedding (representation) space. for multi-property optimization, the proposed research will provide a pipeline structure and new reinforcement learning approaches. to understand and facilitate interpretable generative models, the proposed research will develop a set of novel methods including network dissection, perturbation-based attribution methods, self-explaining methods and disentanglement. this project will have substantial societal and educational impacts, and will enhance **\*\*diversity\*\*** in stem through education and research dissemination. the broader scientific contributions of the will be the development of innovative ai methodologies and tools that will aid drug development. these technical innovations will not only address the key computational challenges in generative models for molecules, but also potentially generalize to other problems (e.g. cheminformatics, materials design) in which generation of structural data is highly needed and interpretation of such generation process is critical. the proposed research can potentially reduce the investment costs during drug discovery, increase its successful rate significantly, and ultimately aid in the improvement of the us health care quality. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: RCN-UBE: Biologists and Graph Interpretation: Professional development for an online curriculum to foster data literacy and value diverse identities

Awardee: SUNY College at Geneseo

Amount: \$499,978.00

Abstract: like other stem disciplines, biology undergraduate students from historically excluded groups graduate at lower rates than their counterparts. to increase student persistence in biology, classrooms should promote student confidence and foster students' sense of belonging. specific strategies towards these goals include improving representation of diverse scientists in the curriculum and incorporating data interpretation skills, which are increasingly critical for student success in biology. however, faculty often lack the experience and resources to create curricula on their own that both highlight counter stereotypical scientists while also addressing complex data literacy skills. in this project, a research coordination network of faculty participants will work collaboratively to create, revise, and disseminate the "biologists and graph interpretation" curricular materials. modules within the curriculum will teach students data literacy skills through an activity that highlights the work of a counter stereotypical scientist. each module will also contain a video interview with that scientist and offer students a moment to reflect on diverse representation in biology. curricular materials produced by network participants will cover both introductory and advanced topics, will include extensive instructor guidelines for classroom implementation, and will be available as open access resources on the quantitative undergraduate biology education and synthesis hub. to further facilitate dissemination of the curriculum, network participants will also lead workshops that guide faculty through the process of finding and incorporating a module into their course. the database of biologists and graph interpretation modules will provide an accessible alternative to textbook resources that historically have not highlighted the work of counter stereotypical scientists. this project will create multiple faculty development opportunities within a supportive network as faculty generate, disseminate, and train others to use "biologists and graph interpretation" curricular materials. to achieve this goal, online faculty mentoring networks will first create, pilot, revise, and publish curricular materials on the quantitative undergraduate biology education and synthesis hub (qubeshub). next, workshops will train new faculty participants in the

implementation of the curriculum. participants will have the opportunity to take leadership roles in future iterations of faculty mentoring networks and workshops. throughout, participants can engage with and support one another via network-wide online activities and discussion boards. partnerships established between this network and other initiatives will facilitate continued growth of this supportive faculty community. the efficacy of the network's professional development will be assessed by monitoring faculty gains, while the impact of the curriculum will be assessed by measuring student outcomes. the **\*\*diversity\*\*** of scientists featured in the curriculum will also be quantified relative to standard textbooks. with more diverse representation and deliberate integration of data literacy skills in biology courses, all students are expected to have a greater sense of belonging as well as an increased confidence in the biology classroom. this project is funded by the directorate for biological sciences, division of biological infrastructure as part of efforts to address the challenges posed in vision and change in undergraduate biology education: a call to action (<http://visionandchange/finalreport/>). this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Dimensions US-China-South Africa: Establishing genetic, phylogenetic and functional mechanisms that shape microbiome diversity of polar and alpine soils

Awardee: University of Delaware

Amount: \$499,973.00

Abstract: microorganisms are the foundations of ecosystems and drive the biology and chemistry in soils, e.g. the conversion of soil organic matter into the greenhouse gases carbon dioxide and methane, as well as nitrogen and phosphorous compounds that can be used by plants. soil microbial community **\*\*diversity\*\*** maintains ecosystem stability and sustainability. understanding the ecology of these microorganisms is one of the most compelling scientific challenges. this project will

focus on the microbial ecology of soil ecosystems in the arctic, antarctic, and tibetan plateau. these ?tri-polar? soils are chosen for study as they are disproportionately impacted by climate change and predicted to show increased microbial activity and enhanced turnover of soil organic matter in the future. while microbes excel at adapting to environmental change, the functional implications of microbial community transitions remain to be characterized. laboratory- and field-based approaches will identify microorganisms that are successful in these ?tri-polar? soil ecosystems and why, i.e., which bacterial species/strains are successful and what functional traits make them successful. understanding how soil ecosystems respond in these polar regions is critical for evaluating the controls of biogeochemical cycling and clarifying microbial feedbacks in a changing world. this project will assemble an international team and recruit young scholars to reflect a blend of expertise in microbiology, ecology and environmental sciences. research will be integrated with educational activities by involving samples and data into hands-on classroom training at the k-12, undergraduate, and graduate levels. this project will delineate mechanisms that lead to diverse soil microbial communities that are hallmarks of stable and sustainable soils. we lack predictive understanding of mechanisms that regulate and maintain microbial bio\*\*diversity\*\* and how this relates to biogeochemically relevant microbial functions. integrative approaches are needed to identify the principles that shape and maintain this bio\*\*diversity\*\*. this project combines genetic, phylogenetic, and functional dimensions of bio\*\*diversity\*\* to probe factors that shape the ?morass of \*\*diversity\*\*? of soil systems. the overarching hypothesis is that resource partitioning, selective predation, and temporal separation of activity each contribute to the success of particular bacterial strains/species in polar and alpine systems. the international research team will focus on testing these hypotheses in soils across arctic, antarctic and tibetan plateau habitats with the acidobacteria as a model microbial phylum for study. laboratory- and field-based approaches will be linked to describe the genetic, phylogenetic and functional \*\*diversity\*\* the acidobacteria, one of the most ubiquitous but elusive bacterial phyla found in terrestrial ecosystems around the globe. the study will identify their ecosystem functions in soils, their interactions with other microbes, their adaptations to

environmental stress such as climate change, and will assess their in situ dynamics and activity. integration of these data will address which organisms compete for resources, avoid predation, and ultimately, occupy fundamentally distinct niches in these ecosystems. elucidating these equalizing/stabilizing mechanisms can begin to explain the tremendous bacterial **\*\*diversity\*\*** observed in soil microbiomes. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: III: Medium: Collaborative Research: MUDL: Multidimensional Uncertainty-Aware Deep Learning Framework

Awardee: University of Texas at Dallas

Amount: \$499,955.00

Abstract: people encounter serious hurdles in finding effective decision-making solutions to real world problems because of uncertainty from a lack of information, conflicting information, and/or unsure observations. critical safety concerns have been consistently highlighted because how to interpret this uncertainty has not been carefully investigated. if the uncertainty is misinterpreted, this can result in unnecessary risk. for example, a self-driving autonomous car can misdetect a human in the road. an artificial intelligence-based medical assistant may misdiagnose cancer as a benign tumor. further, a phishing email can be detected as a normal email. the consequences of all these misdetections or misclassifications caused by different types of uncertainty adds risk and potential adverse events. artificial intelligence (ai) researchers have actively explored how to solve various decision-making problems under uncertainty. however, no prior research has looked into how different approaches of studying uncertainty in ai can leverage each other. this project studies how to measure different causes of uncertainty and use them to solve diverse decision-making problems more effectively. this project can help develop trustworthy ai algorithms that can be used in many

real world decision-making problems. in addition, this project is highly transdisciplinary so that it can encourage broader, newer, and more diverse approaches. to magnify the impact of this project in research and education, this project leverages multicultural, **\*\*diversity\*\***, and stem programs for students with diverse backgrounds and under-represented populations. this project also includes seminar talks, workshops, short courses, and/or research projects for high school and community college students.

this project aims to develop a suite of deep learning (dl) techniques by considering multiple types of uncertainties caused by different root causes and employ them to maximize the effectiveness of decision-making in the presence of highly intelligent, adversarial attacks. this project makes a synergistic but transformative research effort to study: (1) how different types of uncertainties can be quantified based on belief theory; (2) how the estimates of different types of uncertainties can be considered in dl-based approaches; and (3) how multiple types of uncertainties influence the effectiveness and efficiency of decision-making in high-dimensional, complex problems. this project advances the state-of-the-art research by performing the following: (1) proposing a scalable, robust unified dl-based framework to effectively infer predictive multidimensional uncertainty caused by heterogeneous root causes in adversarial environments. (2) dealing with multidimensional uncertainty based on neural networks. (3) enhancing both decision effectiveness and efficiency by considering multidimensional uncertainty-aware designs. (4) testing proposed approaches to ensure their robustness in the presence of intelligent adversarial attackers with advanced deception tactics based on both simulation models and visualization tools. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: RCN: Feedbacks between geological, climatological, and biological dynamics associated with the formation of the Galápagos Islands: The Island Systems Integration Consortium (ISIC)

Awardee: Regents of the University of Idaho

Amount: \$499,866.00

Abstract: the dynamic and changing nature of our planet has long been recognized by researchers in fields such as geology, climatology, and biology. geological and climatological forces influence the formation and maintenance of biological **\*\*diversity\*\***, and evidence from these disciplines is often used to understand these biological patterns. yet, how signatures of current and past bio**\*\*diversity\*\*** patterns may inform geological and climatological models has often been overlooked. this project establishes the island systems integration consortium research coordination network (isic-rcn), a consortium of geologists, climatologists, and biologists focused on determining the potential for each field to inform the others in novel, previously unexplored ways. to do so, the researchers will focus on the galapagos archipelago, an oceanic island system for which ample data have been assembled and that is ripe for such cross-disciplinary analyses. the isic-rcn participants will: (1) form a long-lasting community of researchers whose discipline-focused skills will spawn new interdisciplinary ideas and research directions; (2) quantify the current state of the knowledge about the geological, climatological, and biological understanding of these islands and of ocean islands around the world; and (3) move that understanding forward by addressing outstanding questions in new ways. finally, the isic-rcn will extend its interdisciplinary framework to wider audiences in both the scientific and public spheres by maximizing the **\*\*diversity\*\*** of participants, conducting hands-on training in science communication, providing opportunities and tools to organize galapagos outreach activities, and creation of a website to share galapagos research, isic-rcn scientific advances, outreach activities, and a student-led interactive learning app. the isic-rcn will use the galapagos archipelago as a model to leverage the power of cross-disciplinary research to address fundamental questions too challenging or impossible to address through single disciplinary approaches. activities will align along three primary axes: (1) fostering a unique interdisciplinary community around island systems, using the galapagos archipelago as a focal point, (2) creating new research directions through cross-disciplinary collaboration, and (3) facilitating training and educational activities for

scientists and the general public. to develop and maintain this novel scientific community, the isic-rcn will conduct a series of virtual and in-person meetings, facilitate data sharing and dissemination of scientific knowledge through a web-portal, and support the formation of working groups focused on specific cross-disciplinary scientific questions. products of the isic-rcn include a new community focused on innovative research approaches, new collaborations, white papers on the state of the field and promising avenues of interdisciplinary research, and scientific publications.

Awardee: Georgia State University Research Foundation, Inc.

Amount: \$499,245.00

Abstract: the goal of the project is to train current and future research workforce members in trustworthy artificial intelligence (ai) by developing instructional materials that expose students to various challenges of trustworthy ai systems. the project is focused on the vital national need for well-trained and highly knowledgeable researchers in trustworthy ai who are capable of solving real world problems in complex ai systems and help enable secure and safe adoption of ai systems. the project will have direct and long-term impact in both the public and private sectors by training the research workforce to address trustworthy ai challenges. georgia state university is a minority-serving institution (msi), and the project will form a coordination network consisting of research universities, 4-year colleges, historically black colleges and universities (hbcus), hispanic-serving institutions (hsis), and women's colleges in metro atlanta and the broader region. the collaboration will significantly increase the collective impact of the project, benefit numerous students from underrepresented groups and help increase the **\*\*diversity\*\*** of the research workforce. the project team will develop interactive instructional materials including a set of hands-on labs that employ state-of-the-art trustworthy ai techniques to address the various challenges of ai systems. the instructional materials to be developed include modules on adversarial machine learning, evasion attacks and defenses, data poisoning attacks and defenses, privacy attacks and defenses, testing and verification, and fairness, accountability, transparency, and ethics (fate). the project employs learning science principles, specifically the active learning and inquiry-based learning strategies that result in deeper understanding by students and provide formative feedback to instructors. the instructional materials are based on real-world systems and are designed to systematically cover fundamental principles in trustworthy ai and practical skills. the project also will provide guidelines to help instructors integrate the modules into their curriculum. the hands-on labs will be built based on only open-source software and tools that are free to use for educational purposes and will be distributed via free cloud platforms. the project evaluation includes formative and summative evaluations that use both quantitative and qualitative approaches and will be conducted by an experienced external evaluator with help from the project team. the project will

disseminate the developed materials through training workshops for the educational and research communities. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Redefining the footprint of deep ocean methane seepage for benthic ecosystems

Awardee: University of California-San Diego Scripps Inst of Oceanography

Amount: \$498,985.00

Abstract: this research examines the role of deep-sea organisms in determining the fate and footprint of methane, a potent greenhouse gas, on pacific continental margins. the investigators are evaluating the deep ocean methanosphere defined by the microbial communities that consume methane and the animals that directly feed on or form symbioses with methane-consuming microbes. they are also investigating animal communities that gain energy indirectly from methane, as well as those that take advantage of carbonate rocks, the physical manifestation of methane consumption in seafloor sediments. the study of methane seeps in the deep waters of both alaska (4400-5500 meters) and southern california (450-1040 meters) is enabling comparisons of the methanosphere under different food-limitation and oxygen regimes. by applying diverse chemical, isotopic, microscopy, and genetic-based analyses to seep microbes and fauna, this study is advancing understanding of the contribution of methane to deep-sea bio\*\*diversity\*\* and ecosystem function, information that can inform management and conservation actions in us waters. in addition to training for graduate and undergraduate students at their home institutions, the investigators are collaborating with the alaska native science and engineering program (ansep). they are recruiting alaskan undergraduates to participate in the research, contributing to ansep?s online resources that promote interaction between scientists and middle and high school students, and participating in ansep?s annual residential career exploration in marine science programs to engage middle school

students in learning about deep-sea ecosystems and the variety of career pathways available in marine related fields. microbial production and consumption of methane is dynamic and widespread along continental margins, and some animals within deep-sea methane seeps rely on the oxidation and sequestration of methane for nutrition. at the same time, understanding of methane-dependent processes and symbioses in the deep-sea environment is still rudimentary. the goals of this study are to 1) examine the **diversity** of animals involved in methane-based symbioses and heterotrophic consumption of methane-oxidizing microbes and how these symbioses extend the periphery of seeps, contributing to non-seep, continental slope food webs; and 2) determine whether carbonates on the seep periphery sustain active methanotrophic microbial assemblages, providing a localized food source or chemical fuel for thiotrophic symbioses, via anaerobic oxidation of methane, or free-living, sulfide-oxidizing bacteria consumed by animals. the investigators are addressing these goals by surveying, sampling, and characterizing microbes, water, sediments, carbonates and animals at a deep seep site on the aleutian margin and a shallow site off southern california. shipboard experiments and laboratory analyses are using molecular, isotopic, geochemical, and radiotracer tools to understand transfer of methane-sourced carbon from aerobic methanotrophs under multiple oxygen levels, pressures, and photosynthetic food inputs. this approach offers a wide lens by which to examine the methane seep footprint, allow reinterpretation of past observations, and identify new scientific areas for future study. improved characterization of the deep continental margin methanosphere informs climate science, bio**diversity** conservation, and resource management. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: CICI: UCSS: Helix++: Securing Open Science Platforms

Awardee: University of Virginia Main Campus

Amount: \$498,021.00

Abstract: the helix++ project's goal is to use recently developed, promising cybersecurity research results to secure open-science platforms. securing these open-science platforms is vital because compromise of research infrastructure can have severe consequences, including the delay of critical research, corruption of research results, theft of intellectual property, and exposure of personally identifiable information. beyond providing researchers customized, secure packages of widely used open software, the helix++ project will provide insights and directions for future research and strategies for protecting critical cyber infrastructure. using two existing operational open-science platforms at the university of virginia, the project will investigate the interaction of technical and policy issues which are fundamental to infrastructure protection. the open-source helix++ project improves the security posture of open science platforms by applying cutting-edge cybersecurity techniques to diversify and harden software automatically. a distinguishing feature of helix++ is that it does not require source code or build artifacts. it operates directly on software in binary form—even stripped executables and libraries. this feature is key as rebuilding applications from source is a time-consuming and often frustrating process. helix++ enables the rapid generation and deployment of secure containers and virtual machines, wherein various applications and libraries are transformed to incorporate the helix++ protections. diversification breaks the software monoculture and makes attacks harder to execute as information needed for a successful attack will have changed unpredictably. diversification also forces attackers to customize an attack for each target instead of attackers crafting an exploit that works reliably on all similarly configured targets. hardening directly targets key attack classes. the combination of **diversity** and hardening provides defense-in-depth, as well as a moving target defense. helix++ is evaluated on two open science platforms to demonstrate its efficacy and usability. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: MIM: The impact of the fungal microbiome in metal tolerance and soil biogeochemical transformations

Awardee: University of New Mexico

Amount: \$497,969.00

Abstract: some metals are essential nutrients for life, while some are non-essential or even harmful to living organisms. fungi and bacteria are microorganisms that often live in a close association and play a key role in transforming and detoxifying metals in the environment. in spite of this importance, there is relatively little understanding of how the interactions between bacteria and fungi influence the transformation and/or detoxification of metals. the goal of this project is to address this knowledge gap by identifying how fungal-bacterial interactions affect metal transformation. this will be achieved through a novel multidisciplinary research approach employing advanced, state-of-the-science analytical techniques. knowledge gained through this project will allow the engineered control of metal transformations for a wide range of applications in environmental cleanup, biorefining, production of nanoparticles, and other beneficial applications. successful completion of this research has strong potential to benefit society through improvements in environmental remediation and industrial manufacturing. this project will improve the nation's stem workforce by providing a unique training opportunity for student researchers that bridges diverse fields such as environmental engineering, microbiology, geochemistry, bioinformatics, and art. remediation of metal contamination is a major environmental challenge because, unlike many organic pollutants, metal species cannot be degraded and can only be extracted or biotransformed to less toxic forms. while past approaches to biotransform metals have focused primarily on single microorganisms, host-microbiome interactions have shown potential to biotransform surrounding environments and improve host resiliency. however, the mechanisms for metal biotransformation by microbial host-microbiome systems are largely unknown. the overall goal of this project is to elucidate the rules of life that govern fungal microbiomes. this goal will be achieved through a

specific focus on fungal microbiomes, which include a fungal host, endosymbionts (endobacteria), and symbionts (exobacteria that live extracellularly) as a model host-microbiome system. the specific research objectives of this project designed to achieve the goal are to: understand the effects of metals and metalloids on the **\*\*diversity\*\*** and transmission of fungal microbiomes (facultative and obligatory); and determine the role of fungal microbiomes in metal tolerance by mediating the uptake, transformation, and sorption of metal ions, nanoparticles, or other metal species. a deeply integrated multidisciplinary approach will be used to investigate physiological, genetic/genomic, and metabolic processes that govern the structure and function of fungal microbiomes in the presence of metals. this will be achieved using novel state-of-the-science isotope probing, advanced microscopy, spectroscopy, and integrated genomics, transcriptomics, and metallomics to elucidate how the microbiome influences the metabolic activity of the host towards metal ions. successful completion of this research has strong potential to identify new genes and/or pathways for metal tolerance and biotransformation, as well as expand our mechanistic understanding of the structure and function of fungal microbiomes in nature. this knowledge has strong potential to benefit society by facilitating applications in remediation, water treatment, electronics manufacturing, antimicrobial production, medicine, and related fields. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: RCN-UBE: The River Field Studies Network: Connecting rivers, people, & science through immersive field-based education

Awardee: Virginia Commonwealth University

Amount: \$497,139.00

Abstract: rivers perform a broad set of functions essential to human societies and the landscapes rivers flow through. the relationship between humans and rivers are often impaired, which threatens both rivers and people. restoring these relationships will require a diverse workforce of interdisciplinary problem solvers. field studies are essential to creating this workforce because they connect students to learning objectives, peers, instructors, and society through immersive active learning in real world environments. they help overcome achievement gaps, propel inclusion, catalyze career interest, and create informed and engaged citizens. however, to achieve these benefits, field instructors must overcome a unique and growing set of challenges. in addition to knowledge of their stem discipline, field studies instructors require a sophisticated grasp of

specialized pedagogy and assessment, fundraising, negotiating institutional bureaucracy, issues of **diversity**, equity, and inclusion, and multiple dimensions of risk management. mastering these is more than many self-taught instructors will be able to manage on their own. without a network for support and guidance, instructors will burn out, risk-averse institutions will shy away, and field studies will continue to decline. the river field studies network is a response to the paired crises of rivers and field studies. at this moment of critical vulnerability, we must restore and expand the capacity to bring students and rivers into contact through active learning. the river field studies network aims to advance stem education and support healthy rivers by connecting rivers, people, and science through immersive field education. to accomplish this, the network will, create a dual-track professional-development structure, including a network for mentorship and curricular exchange as well as a more intensive field-based certificate program; develop an online library of open-source lessons and other content for instructors, featuring innovative modules designed to enable student collaboration across institutions and regions; recruit intentionally to overcome barriers to **diversity** of all kinds, and train participants in pedagogical methods that foster inclusivity; tackle the pressing need for informed risk management in field-based education through in-person instruction and expert tutorial videos; reach out to a wider community by building the premier public-facing website for river field studies and creating structures to facilitate student exchange; and incorporate assessment at every level to evaluate and continually refine our programming. these are the essential elements needed to form a sustainable community of practice in river-based education that shares expertise, imparts specialized skills, and cultivates the next generations of leaders, ultimately closing the gaps in institutional capacity that currently threaten the future of the field. this project is funded by the directorate for biological sciences, division of biological infrastructure, as part of their efforts to address the challenges posed in vision and change in undergraduate biology education: a call to action (<http://visionandchange/finalreport/>). this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Nonequilibrium Molecular Dynamics: Dynamical Consistency Across Scales

Awardee: Johns Hopkins University

Amount: \$497,000.00

Abstract: with support from the chemical theory, models and computational methods (ctmc) program in the division of chemistry, professor rigoberto hernandez of johns hopkins university and his team will work to advance the rules describing molecular science at multiple scales. a fundamental challenge to the use of simulation and theory to predict and design chemistry is the requirement that such systems must be specified at atomic resolution, at the scale in which the system functions (generally as large as beaker or a chemical refinery), and everything in between. the coarse-graining of electrons, allowing for the propagation of all-atom molecular dynamics has already proved to be critical in revealing the properties of molecules and assemblies with nearly up to a billion atoms. professor hernandez will develop coarse-grained representations and the equations of motion needed to accurately describe molecular-specified solutions and materials through the middle scales in length and time for systems ranging from a billion to a septillion atoms. dr. hernandez will also advance science generally through his leadership and mentoring of students, staff, chemistry faculties and broader audiences through approaches increasing **\*\*diversity\*\***, equity and inclusion within the chemical enterprise. rigoberto hernandez of johns hopkins university will work to advance understanding and tools for propagating chemical systems that are structurally and dynamically consistent in the sense that observables and their non-equilibrium behavior can be accurately and precisely described at every scale. specifically, the major objectives of his work are to: (i) characterize far-from-equilibrium dynamics of molecular to mesoscale systems driven by macroscale disturbances using reduced-dimensional models; (ii) develop the theory to predict the intrinsic pathways for nonequilibrium pathways in processes involving many particles heterogeneously which is preserved across multiple space and time scales, and (iii) advance the

stochastic hard core (shc) model for complex solvents, benchmark the proposed algorithms for structural and dynamical consistency, and develop a new framework for approximately identifying the pathways in heterogeneous chemical systems exhibiting a hierarchy of interactions at multiple time and length scales. dr. hernandez has also been involved and will continue to be involved in efforts to (i) broaden the use of theoretical and computational tools in chemical dynamics beyond its developers, (ii) increase learning and appreciation of chemistry in the education of undergraduate students and graduate students both inside and outside of the classroom, (iii) engage the general public, and (iv) help diversify the faculty in research-active chemistry departments through his direction of the open chemistry collaborative in **diversity** equity (oxide) and the academic leadership training (alt) workshops. his research findings will be disseminated widely through peer-reviewed publications, and postings on everywherechem, and through scientific and public lectures. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: The Merian Survey. Characterizing Dark Matter and Feedback in Star Forming Dwarf Galaxies

Awardee: University of California-Santa Cruz

Amount: \$496,989.00

Abstract: while most of the mass in the universe is unseen, the smallest galaxies in the universe (the so-called dwarf galaxies) pose significant challenges to this ?dark matter? model. in order to further test our best dark matter models, a large observational survey of dwarf galaxies is needed. this project focuses on the meriam survey, which will observe 100,000 dwarf galaxies with known distances. furthermore, each of the dwarf galaxies in this survey has constraints on their dark matter content from other methods. the new data will provide their stellar structure and colors. these results can all be taken together to test our ideas of dark matter in the universe. the team will place priority

on recruiting a diverse group of students who will carry out the data mining that will be required in the era of the vera rubin observatory. established programs at both princeton and uc santa cruz recruit historically underserved students for summer research and then continuing cohort support. these students will be trained in "big-data" and modern science analysis with merian. extensive studies of dwarf galaxies have revealed a considerable scatter in many of their fundamental properties. in particular, galaxies with stellar mass of  $10^8 - 10^9$  msun present a **\*\*diversity\*\*** of star formation rates and rotation-curve shapes which are in tension with theoretical models. reliably characterizing the dark matter distribution and baryonic processes in these galaxies, such as feedback, is key to in order to establish a complete picture of dark matter on small scales. the merian survey will obtain a volume-limited census of dwarf galaxies in this mass range at  $z=0.058-0.1$ . using two custom made filters, merian will provide redshifts to a complete sample of 100,000 star forming dwarf galaxies (two orders of magnitude larger than sdss+gama) over an area of 870 deg<sup>2</sup>. combined with deep+high spatial resolution imaging from the hyper-suprime camera, this program will result in high s/n weak lensing profile measurements for dwarf galaxies, probing their dark matter halos out to their virial radii. also, hyper-suprime camera imaging will be used to measure dwarf sizes and shapes. the next generation of scientists must be trained to deal with the deluge of vera rubin observatory data coming in the next decade. programs at both princeton and uc santa cruz recruit historically underserved students for summer research and then continuing cohort support. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Genome editing approaches to unravel microRNA roles in stochastic multistable networks

Awardee: University of Texas at Dallas

Amount: \$493,291.00

Abstract: one of the fundamental questions in biology is to understand the roles of the gene regulatory networks driving cellular decisions; cellular decisions drive everything from an organism's development to a cell's fate as healthy or diseased. microRNAs (miRNAs) are small RNA molecules that bind to the mRNA of target genes, acting as regulators of gene expression. Previous studies have demonstrated the critical roles of miRNAs in a variety of biological processes such as cell growth and cell differentiation. However, what is still not well understood concerns possible synergistic effects from multiple miRNA molecules targeting different binding sites of the same mRNA and concerns how miRNA interactions operate within a complex gene regulatory network. To address these issues, an interdisciplinary platform that combines genome editing, live-cell imaging, and mathematical modeling will be developed in this project. The broader impacts of the project from the University of Texas at Dallas side will include support for the International Genetically Engineered Machine (iGEM) team and developing custom educational modules for local schools (Plano ISD) and summer camps, organizing public educational events at the interface of the biological and physical sciences, and the recruitment of underrepresented minorities. From the Northeastern University side, the group will take advantage of the investigators' participation in the NSF Center for Theoretical Biological Physics ongoing **\*\*diversity\*\*** efforts to recruit undergraduates from under-represented to work on this project, and spearhead an effort to create a modeling and computational track for undergraduate bioengineering majors. Finally, both groups will be directly involved in reaching out to local biomedical groups to create more appreciation for the types of rapid progress that can be made by combining advanced tools such as CRISPR with state-of-the-art computational methodology including both mechanistic studies and machine learning approaches. Lying at the heart of intricate relationships that determine the epithelial-mesenchymal transition (EMT) and mesenchymal-epithelial transition (MET) phenotypes is a core regulatory unit that consists of transcription factors and microRNAs. The project will focus on miRNAs targeting the master transcription factor (TF) families of EMTs, Snail and Zeb during the cellular decision process of EMT in multiple cell lines. The team will first perform CRISPR-based screens and custom genome and base editing modifications on miRNA

binding sites that are located at the 3'-utr of the transcription factor families snail and zeb. the effects of binding site modifications in emt and isolated respective clones will be evaluated. second, the team will prepare and optimize an rna imaging platform in live cells and measure time-series data and population distributions for mirna, mrna and protein levels of corresponding genes. using this data, the team will develop stochastic kinetic models of mirna regulation and infer the combinatorial effects of multiple mirna species binding to multiple sites of the same mrna. third, the team will integrate the kinetic models for each mirna interaction into full transcription factor-mirna network models for different cell lines. the models will be refined by calibrating model predictions with experimental observations on the distributions of gene expression and the distribution of cells in various emt states. this project brings together investigators who have extensive experience in genome editing/systems biology (bleris), epithelial?mesenchymal networks (levine), and systems biology/mathematics (lu). this award reflects nsfs statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Role of electric fields and a dynamic local environment in protein-RNA molecular recognition

Awardee: University of Utah

Amount: \$492,516.00

Abstract: ribonucleic acids (rna) are biopolymers with substantial amounts of negative electrical charge, and the surfaces of proteins that bind them often contain amino acid residues with electrical charge that can help attract, direct, and bind their targets. importantly, these are large and flexible molecules so fluctuations in their structure and local environment play a significant role in their function. this project seeks to understand how the process of molecular recognition between rna and proteins is influenced by their electrostatic interactions and by the dynamic environment in which binding occurs by developing a multimodal instrumentation that combines a variety of spectroscopic

techniques. this research will train students in a multidisciplinary skillset at the interface of physical chemistry and biophysics, with broader impacts that include the development of transferrable methods for quantitative characterization of biomolecular interactions. in this project, scalable and quantitative experiment kits for remote learning will be designed and implemented with the goal of expanding hands-on, experience-based education beyond typical teaching laboratory settings.

interactions between proteins and rna show significant **\*\*diversity\*\*** ? proteins can recognize their rna targets in ways that are specific to their sequence, to their structure, to both, or to neither. to uncover the molecular-scale mechanisms that tune substrate recruitment, complex stability, and cooperative target recognition by multiple protein domains, this project integrates electrochemical and spectroscopic tools to measure the dynamic signatures of protein-rna binding, their conformational fluctuations, and their response to non-equilibrium perturbations ? all under the effects of a controlled electrostatic environment. rna substrates will be localized at an electrode surface to tune their electrostatic interactions with proteins in solution, and the resulting protein-rna complexes will be probed with a multimodal instrument that combines electrochemistry with mid-infrared plasmonics, ultrafast multi-channel fluorescence, and pump-probe spectroscopies. the outcomes of this research will reveal the way electrostatic interactions and fast dynamics of biomolecular structure and solvation affect the thermodynamics and kinetics of formation, stability, and dissociation of protein-rna complexes. this project is supported by the molecular biophysics cluster of the division of molecular and cellular biosciences. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Predicting impacts of coastal species redistribution in a changing climate

Awardee: University of California-Irvine

Amount: \$492,382.00

Abstract: this project will improve our ability to anticipate the impacts of shifts in the geographic range of coastal species in a changing climate. although range shifts may be necessary for some species to avoid extinction as the climate warms, the arrival of new ones to an ecosystem can also lead to population declines and loss of bio\*\*diversity\*\*. the investigator is developing approaches to predict the impacts of range shifts along pacific shorelines using techniques that have been previously validated for risk assessments for invasive species. the research objectives of this study are integrated with educational activities: engagement of undergraduate and graduate students in data collection and analysis and implementation of a hierarchical mentoring program to serve english language learners within the investigator's minority serving institution. the investigator is also partnering with outreach organizations in the u.s. and mexico to educate k-12 students and multiple stakeholder groups about climate-driven range shifts and tools for predicting outcomes of redistribution, which can assist practitioners in creating management plans and policies. this study is developing a framework for understanding the impacts of marine species redistribution with a focus on poleward-moving carnivorous whelk species in rocky shorelines from northern california to baja, mexico. project goals are to 1) quantify the impacts of shifting species on populations and communities in the expanded range; 2) assess whether impacts of shifting species differ between their native and expanded ranges; and 3) predict future impacts under climate warming. the investigator is addressing fundamental questions in community ecology about the degree to which species interactions are density- and context-dependent. she is combining observational and experimental approaches with a broader data synthesis effort to test whether the impacts of species redistribution can be predicted by key indicators of invasion impacts: abundance, trophic level, and impacts in the native range. empirical data combined with paired demographic and distribution modeling will be used to project future impacts across the expanded ranges of these coastal marine species. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: CAREER: Leveraging Microfluidics for High-Throughput in Vitro Investigations of Transcriptional Regulation

Awardee: Stanford University

Amount: \$490,977.00

Abstract: all biological processes depend on the precise regulation of when genes are transcribed and how many rna transcripts are produced. this regulation is driven primarily by transcription factor (tf) proteins that bind specific dna sequences in the genome and then recruit additional "effector" proteins to either activate or repress gene transcription. while scientists have "cracked" the dna code specifying the sequences of rna and protein molecules produced from protein-coding dna, it remains unclear how the tf/dna "regulatory" code that governs the strength and timing of gene expression. it is not known how closely related tfs with apparently similar dna binding preferences recognize different sites in the genome to regulate distinct transcriptional programs. there is little known about the web of interactions between tfs and the "effector" proteins required to activate transcription. this project will utilize new microfluidic technologies that enable accurate measurement of 1000s of protein/dna and protein/protein binding interactions simultaneously and at low cost. this project will apply these technologies to better understand how tfs find and bind their dna targets, how bound tfs recruit "effector" proteins, and the degree to which the "regulatory code" relies on thermodynamics. the pi will expand a hands-on microfluidics device laboratory to provide inquiry-based summer research experiences to community college students, increasing training opportunities for student populations traditionally underrepresented in stem. regulated gene expression is central to biology, sculpting the transformation from embryo to animal and enabling cells to respond dynamically to environmental changes. at a molecular level, this regulation is accomplished primarily by transcription factor (tf) proteins that bind dna regulatory elements and then recruit additional protein cofactors to either activate or repress transcription. biological \*\*diversity\*\* is simply too vast for us to ever measure tf binding and transcription in all organisms

and all tissues under all conditions of interest. this project will provide in vitro measurements that quantify thermodynamic and kinetic constants of reconstituted macromolecular interactions at unprecedented scale by using multiple novel microfluidic platforms capable of measuring affinities and kinetics for up to one million protein/dna or protein/protein interactions in parallel that were developed in the pi's laboratory. in this project, these in vitro technologies will be used to develop quantitative and predictive models of how tfs find and bind their genomic targets and how bound tfs recruit cofactors to regulate gene expression. using cutting-edge in silico tools, these measurements will then be integrated with existing in vivo data sets to develop quantitative models that, in turn, will be directly tested in vivo by quantifying tf and cofactor binding and gene expression for sequence variants. this project is funded by the molecular biophysics and genetic mechanisms clusters in the division of molecular and cellular biosciences. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: NSF-BSF: Elucidating Interactions between Multiple Optical Cycling Centers in Hypermetallic Polyatomic Molecules

Awardee: Smithsonian Institution Astrophysical Observatory

Amount: \$490,503.00

Abstract: laser-cooled molecules are a powerful tool for exploring the frontiers of quantum science and ultracold physics, provided their energy can be cooled in all degrees of freedom to temperatures very close to absolute zero. although certain classes of molecules can be cooled with precisely engineered laser-light, particularly those containing a single heavy atom, extending efficient laser cooling to molecules more generally has proven challenging. this project aims to understand the general design principles that affect the performance of exotic, new classes of laser-coolable molecules containing multiple heavy atoms. through a collaborative national science foundation - us

israel binational science foundation experimental program, the investigators will explore how light from radio to visible wavelengths interacts with such molecules. this effort will broaden the **\*\*diversity\*\*** of cold molecule applications spanning quantum computing and simulation to tabletop searches for new physics. such cutting-edge yet fundamental measurements are well suited to educating and training students in stem fields, and such mentorship is a core project aim. all demonstrations of direct laser-cooling to date have used molecules containing a single heavy-atom photon-cycling center. more complex species containing multiple optical centers have the potential to greatly increase the versatility of laser-cooled molecules, but have not been thoroughly explored experimentally. this program comprises a systematic spectroscopic study of substituted hydrocarbons, including acetylene chains and benzene rings, containing multiple alkaline earth or alkaline-earth-like atoms. by combining broadband optical and microwave data, the investigators will directly probe how the intricacies of electronic structure and chemical bonding influence the molecular properties relevant to laser-cooling applications, as well as the molecular physics of these exotic, biradical species in general. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Awardee: Indiana University

Amount: \$490,000.00

Abstract: with support of the macromolecular, supramolecular, and nanochemistry program in the division of chemistry, professor amar flood of indiana university will undertake a project to understand how to design molecular compounds to capture negatively charged ions (anions) and use them to synthesize more complex chemical compounds. the significance of studying anions stems from their many global impact areas spanning from the use of nitrate and phosphate as fertilizer, which impact food production and water quality, through to organic phosphates that are the workhorse anions in lithium ion batteries. the significance of anion-directed synthesis is inspired by nature's use of bottom-up self-assembly and has the potential to impact the future of nano-manufacturing. the planned activity will benefit society by training graduate, undergraduate and postdoctoral coworkers in research, communication and collaboration both nationally and internationally. inclusive practices will be developed that foster a culture that embraces **\*\*diversity\*\*** and equity in stem (science, technology, engineering and mathematics). this project also has the potential to broaden understanding of anion-based chemistry for the public and undergraduate communities with videos and laboratory experiments. outputs from this research are expected to offer benefits to researchers in other areas of chemistry, and to industries that need to manipulate

anions. in this project on anion recognition and anion-driven hierarchical assembly, professor amar flood and his team will synthesize a series of anions to control their modes of self-assembly, study their anion recognition by cyanostar macrocycles, and examine their mechanisms and cooperativities of self-assembly. the project has three aims. aim 1 seeks to determine how the sterics, electronics and charge of substituents on anions composed of trifluoroborates control formation of cyanostar complexes by using synthesis, titration data and crystal structures. aim 2 aims to establish the correlation between the structures of substituted phosphates and their mechanisms of threading inside cyanostar macrocycles and to make threaded polymers with beads-on-a-string structures. aim 3 seeks to expand the role of anions in hierarchical self-assembly synthesis by understanding how anions and cyanostar structures need to be programmed to produce specific architectures that include network gels, cyclic polymers, and spherical cages. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: AF: Medium: A Unified Framework for Geometric and Topological Signature-Based Shape Comparison

Awardee: Tulane University

Amount: \$489,744.00

Abstract: a fundamental aspect for data analysis is the ability to compare data sets, in order to measure (dis)similarity and quantify patterns present in the data. however, data is often too large and complex to analyze in its entirety, and therefore different techniques are used to summarize the data in order to work with smaller, more manageable representations of it. this project studies the data-comparison problem through the lens of mathematics, using geometric and topological signatures to represent these shapes concisely. this project will consider a variety of different kinds of shape data which live in some larger geometric or topological space (e.g., gis trajectories, point

sets, meshes, 3d scans, or graphs), and consider classes of algebraic, geometric, and graphical signatures which can be used to represent these shapes concisely. the project draws primarily upon the nascent yet rapidly developing area of topological data analysis, where tools from topology like homology or homotopy are combined with geometric measures to create robust analysis tools for analyzing the shape of data. graduate and undergraduate students will be tightly integrated into the project, and special efforts will be made to involve students from underrepresented groups. additional efforts by the research team include planning a workshop focused on women in this field, as well as broadening **\*\*diversity\*\*** and inclusion efforts in their own universities. the project focuses on shapes that have some common underlying annotation framework on top of the signature, which is usually additional structural or geometric information from the original embedding. the research consists of two major components. in the first, the investigators are initiating a principled study of algorithms and approaches to develop a unified framework which leverages multiple signatures for shape comparison. the goal of this phase is to provide theoretical results as well as empirical evaluations on a variety of data sets and signatures. the second major component of the project studies inverse problems, which aim to reconstruct shapes from a combination of signatures. such problems are notoriously difficult for geometric or topological signatures, as they are necessarily lossy and remove certain types of information. during the course of the project, the investigators are also developing a shape signatures toolkit that enables computation of a range of signatures and distances, adding to the software both existing notions of distance and new ones developed over the course of the project. this project is jointly funded by the algorithmic foundations core program and by the established program to stimulate competitive research (epscor). this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Testing the reduction of aerobic habitat as a common kill mechanism for major mass extinction events

Awardee: Syracuse University

Amount: \$488,302.00

Abstract: the project will study the response of marine animal ecosystems to environmental change using three mass extinction events from the geological record as study systems. specifically, the project will test the hypothesis that a large proportion of extinction during these events can be explained by the stresses that elevated temperatures and reduced oxygen availability place on animal respiration. geochemical data will be used to constrain computer simulations of changing ocean conditions during these mass extinction events. results from laboratory studies on animal respiration will then be paired with fossil data to assess whether differences in extinction intensity in space and across taxonomic groups can be explained by spatial variation in environmental change or differences among taxonomic groups in their ability to withstand environmental change. the project will provide interdisciplinary training to a group of graduate students and post-docs. it will further impact stem education through the creation of a website that will allow access to model results so that students can visualize and explore model output to understand cause-effect relationships between continental configuration, ocean conditions, and biological **diversity**. the investigators will also offer short-courses on earth system modeling and data interpretation at major conferences that will be recorded for asynchronous use. the project will also involve the development of a podcast series addressing how we reconstruct the ancient earth system and use these reconstructions to better understand the present and predict the future. in this project, the hypothesis will be tested that the loss of habitat through constraints on aerobic respiration under climate change and ocean deoxygenation can explain the magnitude, taxonomic selectivity, and latitude variation in intensity for the late devonian (frasnian-famnenian), end-permian, and end-triassic mass extinction events. paleoredox and paleoclimate proxy data and geochemical indicators of diagenetic alteration will be used for both global average and local conditions before

and after each major event combined with predictions from earth system models and occurrence data from the fossil record of marine animals to separate aspects of extinction than can be explained by physiological stress from those that require other explanations. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Testing Hypotheses about Rates of Diversification & Controls on Diversification related to the Opportunities for Speciation vs Fate of Incipient Divergences

Awardee: Mississippi State University

Amount: \$487,275.00

Abstract: all of combined planetary bio\*\*diversity\*\* owes its existence to the formation of new species. it is the newly formed boundaries separating one group of individuals from others that maintain the distinct and unique characteristics of individuals in each species. new species can form quickly or slowly. depending upon this pace of species formation (i.e., the rate of diversification), the numbers of species within a group will differ. however, the diversification rate itself is not sufficient to understand why species \*\*diversity\*\* varies because there are multiple potential explanations for any estimated diversification rate. this research project will focus on statistically distinguishing among these different explanations in order to understand why species \*\*diversity\*\* differs across

space, time, and among different groups of organisms. specifically, by applying newly developed statistical models of species formation to genomic sequences from individuals collected across multiple populations within each of several hundred species, the research will distinguish between various potential controls on diversification. these alternative controls have never previously been tested within a single study. as such, the research will provide unprecedented insights into how the frequency of formation and persistence of isolated populations (and hence, the opportunities for new species to form) affects diversification rates. the targeted study group (north american melanoplinae grasshoppers) includes representatives that span the climatic, geographic, and ecological conditions theorized to affect species formation, which will provide robust tests of how bio\*\*diversity\*\* is shaped. by illustrating the utility of population-level sampling within species in tests of species formation, the project will set a new benchmark for other researchers to consider for their own bio\*\*diversity\*\* studies. such research is important to avoid misinterpretations about why bio\*\*diversity\*\* differs across geographic regions, or among habitats, or among groups of organisms that co-occur. the research will also highlight the importance of museum collections for genomic-era bio\*\*diversity\*\* studies, while enhancing this publicly accessible community resource through the addition of newly collected and curated specimens, including their dna, ecological and geographic information. a complementary program of public and educational outreach activities built around the core research objective of why diversification might be promoted (or inhibited) across different landscapes or organismal groups will reach a diverse audience.       \*\*diversity\*\* differences

observed across taxonomic groups reflect different rates of diversification. however, there are two fundamentally different controls on diversification dynamics (meaning there are different explanations for any given diversification rate): the evolution of reproductive isolation that affects the fate of incipient divergences versus the frequency with which isolated populations form and persist affecting the opportunities for speciation. because diversification studies are typically carried out on phylogenetic estimates of species lineages, it has not been possible to test hypotheses about the opportunities for speciation. this research addresses this knowledge gap. through combined

theoretical and empirical studies and the generation of large-scale genomic data, the research will apply newly developed analytical methods to test hypotheses about diversification rates (based on phylogenetic estimates of species lineages) vs. the controls on diversification dynamics (based on phylogenetic estimates of species and population lineages). by testing for linkages between different controls on diversification dynamics with factors potentially affecting the formation of new species (e.g., fragmented habitats, topographically complex landscapes, or periods of climatic change, and species-specific traits), the work will address why these conditions might promote or inhibit the formation of new species. this will be the first study to establish potential linkages between the various controls on **diversity** dynamics (e.g., topographic complexity, geologic and climatic events, and selectively driven divergence). leveraging the researchers' extensive specimen collections with advances in collecting large-scale genomic data across hundreds of thousands of individuals and state-of-the-art analytics, the empirical dataset will contain almost complete taxonomic coverage of over 600 closely related grasshopper species (355 of which are from a single genus) that radiated recently (i.e., within the pleistocene and pliocene) in north america and mexico. by combining the skillsets of researchers with taxonomic expertise and genomic and quantitative analytics, the research team will promote broad training and mentoring of graduate students, while also offering public and educational outreach activities developed by researchers with different backgrounds to reach diverse audiences and underserved communities. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Microdiversity drives ecosystem function: SAR11 bacteria as models for oceanic nitrogen loss

Awardee: Montana State University

Amount: \$486,782.00

Abstract: this project studies how low oxygen availability influences the bio\*\*diversity\*\* and ecological role of sar11 bacteria, one of the most abundant microbial groups in the ocean. the work involves oceanographic sampling across a range of oxygen and nutrient levels in the eastern tropical north pacific ocean. using a combination of genomic, microbiological, and biogeochemical methods, the study identifies the mechanisms by which sar11 strains diversify into separate niches and species and contribute biochemically to the ecosystem, likely through removing nitrogen from seawater. the project equips the next generation of researchers and educators, notably those from underrepresented minority groups, to use oceanographic, genomic, and microbiological concepts to meet contemporary scientific challenges. this goal is met through a combination of bioinformatic workshops that target undergraduate students from the university system of puerto rico, middle school teacher-training workshops, and middle or high school teacher internships in the investigator?s labs. this multifaceted research and educational agenda fills a gap in our understanding of marine biological \*\*diversity\*\*, identifies the contribution of sar11 bacteria to nutrient and carbon cycles in low oxygen oceans, and provides lessons and analytical tools to study microbial processes in other ecosystems. this project has two aims. aim 1 employs comparative metagenomic and single-cell genomic analyses to identify metabolic properties that distinguish sar11 clades from low oxygen regions and processes of selection or gene flow operating across the clades. aim 2 combines microbial transcriptomics, incubation experiments with isotope tracers, and culturing to delimit the oxygen and nutrient conditions that define the niche space of each sar11 clade and to correlate sar11 gene transcription with community biochemical outcomes, including nitrogen loss through denitrification. the results of these aims and the informatic methods used to probe microbial micro\*\*diversity\*\* are disseminated through genomics-focused undergraduate workshops, and new teacher-training educational modules, including lab-based modules focused on the importance of microorganisms under environmental change in the oceans. data, manuscripts, and informatics workflows from this project are made publicly available. the results are critical for resolving the processes that create and sustain microbial \*\*diversity\*\* in the oceans and informing

biogeochemical models that predict how **diversity** influences ecosystem processes. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: CSBR: An inordinate fondness for beetles - expanding access to the Triplehorn collection of Coleoptera, phase 2

Awardee: Ohio State University

Amount: \$484,967.00

Abstract: the specimens held in natural history collections are the documentation of the world's bio**\*\*diversity\*\***, including what the species are, where they live, their life history, and their

relationships with other organisms. the specimens and the information associated with them are a timeline that records the changes in flora and fauna that have resulted from growing human populations, changing land use patterns, habitat alterations, species extinctions, and the introduction of invasive species. these specimen records are invaluable and irreplaceable, but they are also irrelevant unless they are both secure and accessible. to be secure, specimens must be protected from environmental hazards such as heat, humidity, light, and pests. accessibility encompasses equally the physical availability the materials for researchers to study through visits and loans as well as free and open access to the data associated with the specimens using information technologies. the process of photographing, copying and uploading data itself requires the ability of workers to remove and handle specimens. recording of data and quality control can be a prolonged and expensive process. however, it is also a valuable opportunity to engage with the general public in the documentation of their own biological heritage. this not only contributes to a better understanding of the inner workings of natural history collections, but how and why scientists explore the natural world. this project will provide the physical and virtual access needed to the hundreds of thousands of beetle specimens housed in the triplehorn insect collection at the ohio state university. beetles are the most species-rich group of plants or animals in the world, and they include many species that are serious pests of food and forests as well as beneficial species that keep pests at low population levels. the researchers in the collection will rehouse the specimens in new, secure cabinets, drawers and unit trays. the work will be coordinated with transcription of the data on the labels attached to each specimen. these data will then go through a quality assurance check before being stored in the collection's electronic database. this information resource is open to the general public, and its contents are automatically shared with idigbio, the national clearinghouse for bio\*\*diversity\*\* information, and the global bio\*\*diversity\*\* information facility, the worldwide counterpart. the data associated with the collection of tiger beetles will be the focus of a citizen science collaboration. the specimens and labels will be photographed and uploaded to notes from nature, and with the help of lay collaborators, the data will be transcribed and then uploaded

into the collection database. this work will then ensure the maintenance and availability of specimens and their data for future research, resources that are the results of more than a century of collecting effort. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: CAREER: Identifying the Role of Tandem Repeats in Great Ape Adaptation through Undergraduate Team Research Using a Novel Statistical Framework

Awardee: San Francisco State University

Amount: \$483,199.00

Abstract: this award is funded in whole or in part under the american rescue plan act of 2021 (public law 117-2). this project will substantially expand our ability to study rapid trait evolution. rapid trait

evolution results in dramatic differences between closely related species, such as chimpanzees and humans. the way genes are used (gene expression) has been implicated in such differences, but the genetic basis for altered gene expression is poorly understood. until recently, because of limits in dna sequencing techniques, a major source of genetic variation (tandem repeats) has been difficult to study. while sequencing technology has advanced so that we can produce these data, we still lack a way to analyze it. this project will create a new analysis tool and will demonstrate its use by studying great ape evolution, addressing longstanding biological problems such brain evolution. further, this project will support the professional development of undergraduate and masters student scientists, mostly persons excluded due to ethnicity, race, and gender, improving the **\*\*diversity\*\***, rigor, and relevance of science in the long term. specifically, this project will complete the following objectives: (1) create treva, a statistical tool that uses tandem repeat (tr) variation data between and within species to test evolutionary hypotheses, in particular to identify trs under balancing or directional selection; (2) apply treva to empirical data to determine how tr variation underlies adaptation in great apes; (3) identify genes impacted by trs under selection and determine the downstream biological processes and traits under selection. this project will integrate education into research using three mechanisms. (1) the research will primarily be carried out by san francisco state university (sfsu) undergraduates and master's students. (2) the project will create the computational research introductory summer program where sfsu masters students will be supported to mentor teams of novice sfsu undergraduates to learn computer science skills and apply them to original research projects. (3) students performing the research will create video abstracts describing their work, which will be used in science classes nationally to engage students with diverse scientists. this project is co-funded by the biological anthropology program in the division of behavioral and cognitive sciences. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Quantum Transport in Self-Assembled Hybrid Superlattices

Awardee: Florida State University

Amount: \$483,006.00

Abstract: new phenomena emerge when two semiconductors are brought together in a periodic structure. such semiconducting superlattices have properties not observed in bulk semiconductor crystals. their unique properties have led to novel devices such as tunable optical filters, infrared photodetectors, and quantum cascade lasers. superlattices are expensive to make, requiring ultrahigh vacuum and meticulous layer by layer assembly. the project aims to discover a new type of superlattice based on hybrid perovskites, materials with both organic and inorganic components. hybrid perovskites can be solution processed, allowing for spontaneous assembly into layered nanostructures. their chemical **diversity** can revolutionize superlattice research with a vastly expanded range of materials with varied properties. this research will enable future superlattice devices that are scalable and cost-effective. this project will also provide interdisciplinary training to undergraduate and graduate students, providing them with critical-thinking and problem-solving skills needed for careers in stem and industry. semiconducting superlattices are quantum heterostructures important to condensed matter physics and with applications in advanced electronic technologies. the constituents of the superlattices to date have been limited to inorganic semiconductors, such as GaAs and AlGaAs. this project will investigate quantum transport in a new class of semiconducting superlattices based on Ruddlesden-Popper halide perovskites. the project will employ theoretical and experimental studies in an iterative manner so as to accelerate materials discovery. first principle density functional theory (DFT) calculations will be used to predict materials structures and the optical and electronic properties will be modeled by combining tight-binding models with the DFT calculations. superlattice structures will be prepared by solution processing and self-assembly, allowing for facile tuning of the electronic structure by varying constituents. the design strategy, using semiconducting organic ligands, will create new possibilities for band

engineering. electrooptical measurements will be used to identify signatures of semiconducting superlattices such as electronic minibands. complementary electrical characterization will be used to search for evidence of quantum transport, using optical excitation to generate charge carriers without unintended effects arising from doping. the project will elucidate the properties of 2d perovskite superlattices, differentiate their behaviors from conventional inorganic superlattices, and determine if their optical and electronic properties can be tailored in a controllable manner. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: CAREER: QUANTUM MATERIALS IN SQUARE-NET BASED COMPOUNDS

Awardee: Princeton University

Amount: \$482,515.00

Abstract: this award is funded in whole or in part under the american rescue plan act of 2021 (public law 117-2). non-technical summary so-called "quantum-materials" are materials that do not follow the laws of classical physics. examples are superconductors, complex magnets, or topological materials. topological materials are a class of quantum matter that show promise to enable future technologies such as new devices for data storage or quantum computing. not much is yet understood, however, about the materials chemistry of topological matter. with this career award, professor leslie schoop at princeton university aims to understand how the discipline of solid-state chemistry can impact the understanding of topological matter. towards this goal, the team will focus on a particular class of crystalline compounds: those in which atoms arrange in a square-net fashion. in these materials, electronic properties can be understood on the basis of the chemical bonds in the square lattice. understanding the nature of the chemical bonds then allows the intentional modification of these bonds and how this effects physical properties, such as electronic and magnetic properties. ultimately, prof. schoop's team will create a recipe for

discovering quantum properties in materials with square nets. this proposal also includes outreach to community colleges by providing support for students from new jersey-based community colleges to spend a summer in the schoop lab to learn more about quantum materials synthesis. the pi will visit these community colleges to give lectures targeted to a general audience to provide basic insights to the complex and exciting field of quantum materials. technical summary with this career award, professor leslie schoop at princeton university aims to establish predictive power for the development of new quantum materials based on a class of compounds with a common structural motif - a square net. in this class of materials, a topological electronic structure can be linked to the type of chemical bonding within the square net. this delocalized bonding has been classified as hypervalent and is in direct competition to a charge density wave-type lattice distortion. the aim here is to understand the effect of such distortions on the topological band structure. charge density waves in topological materials have recently gained attention because they provide a pathway for the creation of multiple new correlated topological phases that still have yet to be discovered. this project addresses the current challenges from a chemical angle. the second aim is to use the structural distortions as a tool to create materials with complex magnetism. magnetism has the potential to add electron-electron correlation to a topological material. such correlated topological materials are believed to result in the discovery of yet unknown physics, which could lead to new quantum devices. the goal will be reached by synthesizing and structurally characterizing multiple square-net materials, as well as by varying their composition. the structural data will be used to derive chemical rules for structural distortions. finally, the magnetic and electronic properties of the synthesized compounds will be investigated. the broader impacts consists of student education; a commitment to **diversity**; service to the community; and the potential for advancing technology. the pi will provide opportunities to new jersey community college students to work in her lab while reaching out to these campuses with public lectures to help underrepresented minority students understand different possible stem career paths. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the

foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Dynamics of Seasonal Forecast Uncertainty: Cross-Basin Ocean-Atmosphere Interactions

Awardee: University of California-San Diego Scripps Inst of Oceanography

Amount: \$482,252.00

Abstract: every few years the pacific ocean warms dramatically in a narrow strip along the equator extending roughly from the south american coast to the dateline. this warming is called an el nino event, and el ninos and their cold la nina opposites are referred to collectively as el nino/southern oscillation (enso) events. while enso events are broadly similar there are important differences, in particular they differ in whether the sea surface temperature (sst) change is greatest in the eastern or central pacific. they also differ in their magnitude, and el nino events are often stronger than la nina events. the consequences of enso are felt worldwide, from changes in the indian monsoon to the severity of winters in canada, and these impacts vary according to the pattern and magnitude of the event. the dynamical mechanisms that cause **\*\*diversity\*\*** in behavior among enso events and their global impacts are thus an important practical problem as well as a topic of scientific interest.

this project examines the idea that much of the **\*\*diversity\*\*** of enso events occurs because of interactions between the developing enso event and a variety of less prominent climate variability modes occurring over the global oceans. for example the pacific meridional mode (pmm) is a variability pattern in which fluctuations of the aleutian low over the north pacific generate warm ssts (or cold, in the opposite phase) which propagate slowly toward the equatorial pacific through air-sea interactions. the overlap between the domains of the pmm and enso makes the pmm a likely suspect in diversifying enso events. likewise, the episodic warming of the indian ocean in the indian ocean dipole (iod) mode affects the trade winds in the western pacific, with potential consequences for enso given the central role of trade wind fluctuations in enso evolution. to examine the effect of

secondary modes on enso **\*\*diversity\*\*** the principal investigators (pis) of this award take advantage of the ensemble method used to predict enso events. ensemble prediction means using a climate model to predict enso based on observed initial conditions (the state of the atmosphere and ocean at a given time) but performing several forecast simulations instead of one, and starting each forecast simulation with slightly different initial conditions. the resulting perturbed initial condition ensemble (pice) gives a best estimate of the evolution of enso and also estimates the uncertainty in the prediction. the idea of this project is that the individual forecast simulations in a pice contain different secondary modes, and the interactions between secondary modes and enso can be assessed by examining differences in enso evolution among the simulations. an advantage of this method is that a large database of pice simulations has been created by the earth system prediction (esp) working group of the community earth system model (cesm). the pice dataset provides a much larger sample size than the observational record, thus statistically robust results can be obtained. the work is of societal importance given its direct connection to enso prediction. in addition to its examination of enso evolution in prediction simulations the research uses the pice simulations to understand how differences among enso events lead to differences in the impacts of enso in populous parts of the world. the project also supports two graduate students and provides internship opportunities for undergraduates. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Life in Ice: Probing Microbial Englacial Activity through Time

Awardee: Montana State University

Amount: \$481,268.00

Abstract: glacial ice cores serve as a museum back in time, providing detailed records of past climatic conditions. in addition to chronological records such as temperature, chemistry and gas

composition, ice provides a unique environment for preserving microbes and other biological materials through time. these microbes provide invaluable insight into the physiological capabilities necessary for survival in the earth's cryosphere and other icy planetary bodies, yet little is known about them. this award supports fundamental research into the activity of microbes in ice, and directly supports major research priorities regarding antarctic biota identified in the 2015 national academies of sciences, engineering, and medicine report, a strategic vision for nsf investments in antarctic and southern ocean research. the broader impacts of this work are that it will be relevant to researchers across paleoclimate and biological fields. it will support two early career researchers, a graduate and an undergraduate student who will conduct laboratory analyses, participate in outreach activities, publish papers in scientific journals and present at conferences. this work will use previously collected ice cores to investigate englacial microbial activity from the holocene back to the last glacial maximum from the blue ice area of taylor glacier, antarctica. the proposal identified making significant contributions to 1) investigating how antarctic organisms evolve and adapt to changing environment, 2) understanding how microbes alter the preservation of paleorecord-relevant gas and trace element information in ice cores, and 3) identifying microbial life in cores and their activity in relation to dust depositional events. two recently developed complementary techniques (bio-orthogonal noncanonical amino acid tagging and deuterium isotope probing) in combination with raman confocal microspectroscopy will be used to assess and quantify microbial activity in ice. during phase one of the project, these methods will be optimized using deaccessioned ice cores available at the national science foundation's ice core facility. in phase two, ice cores in a time series from the taylor glacier will be analyzed for geochemistry and microbial activity. research results will provide a comprehensive view of englacial microbial communities, including their metabolic **diversity** and activity, and the effect of geochemical parameters on microbial assemblages from different climate periods. given the dearth of information available on englacial microbial communities, the results of this research will be of particular significance. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation

using the foundation's intellectual merit and broader impacts review criteria.

Title: CAS: Enhancing the Reactivity and Photoreactivity of Metal Oxide Surfaces through Fluorination

Awardee: Cornell University

Amount: \$480,000.00

Abstract: with the support of the macromolecular, supramolecular, and nanochemistry program in the division of chemistry, dr. melissa hines of cornell university will investigate the reactivity and photoreactivity of fluorinated and fluorine-doped titanium dioxide using scanning tunneling microscopy, x-ray photoelectron spectroscopy, and density functional theory. the resulting atomic-scale understanding of these surfaces is expected to contribute to the development of sustainable, non-toxic, earth-abundant nanocatalysts and photocatalysts. dr. hines and the research team are advancing discovery in nanocatalysis, sustainable chemistry, and surface science. this research is also training the next generation of scientists in a field that is important to maintaining us economic competitiveness. to increase the number and **\*\*diversity\*\*** of students entering science and technology fields, they are developing modules for middle school students that focus on quantitative measurements and scientific experiments that engage both students and faculty. this

research involves the development of chemical reactions and an ultraclean reactor to study the solution-phase chemistry and photochemistry of fluorinated titanium dioxide. this includes the determination of the primary mechanisms that lead to fluorine-functionalized titanium dioxide surfaces and the role of photogenerated charge carriers in these mechanisms, identification of new fluorination agents for preparing atomically flat fluorinated titanium dioxide surfaces, and assessment of the impact of fluorination on the photoreactivity of titanium dioxide. this research will also address the photo-fluorination of organic acids in aqueous solution. developing an atomic-scale understanding of these surfaces and their reactivity has the potential to enable the production of passivated, contamination-resistant metal oxide surfaces and high reactivity photofluorination catalysts that operate under more environmentally friendly conditions than current catalysts. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Novel Imine Formation by ATP Grasp Enzymes

Awardee: University of Florida

Amount: \$480,000.00

Abstract: with the support of the chemistry of life processes program in the division of chemistry, dr. yongsong ding will collaborate with drs. steven bruner and gustavo seabra, all from the university of florida, to study the mechanism for the formation of an imine bond (carbon connected to nitrogen by two bonds) by members of an enzyme superfamily known as atp grasp enzymes. imines are essential to a number of life processes and they are formed during many types of enzyme-catalyzed reactions. however, little is known about how enzymes in the atp grasp enzyme superfamily catalyze

imine formation. the atp grasp superfamily has about 550,000 members, some of which catalyze reactions for central biological pathways, e.g., making proteins, cell-walls, and fatty acids. using a suite of biochemical, structural and computational tools, the research team will characterize how two atp grasp enzymes promote the formation of imines for the production of complex molecules found in nature and discover new compounds and processes driven by imine-forming atp grasp enzymes. this project aims to deliver novel insights into how nature has devised novel functions in the same enzyme family and reveal how these enzymes could aid in making complex molecules for applications in biotechnology. furthermore, this project will provide opportunities for training students, particularly women and underrepresented minorities, in modern scientific techniques, thereby preparing them for advanced careers in science. through established collaborations with the center for undergraduate research, summer undergraduate research at florida, and the center for precollegiate education and training at the university of florida, this project will also engage high school and college students in the research and magnify its broader impacts through outreach activities for high school teachers. the imine is important as a key reactive intermediate species in a number of enzyme catalyzed reactions and as an emerging functional group of bioactive small molecules. atp grasp enzymes are known to form the amide, ester or thioester linkage. however, two atp grasp enzymes mysc and mysd catalyze imine formation for the biosynthesis of natural uv protectants mycosporine-like amino acids (maas), representing new chemistry for this enzyme superfamily. this project will investigate the molecular basis for fundamental deviations from the canonical reaction mechanism for atp-dependent grasp enzymes that favor imine formation here. specifically, the research team will characterize the reaction paths, substrate requirements, kinetic details, and unique structural features of mysc (objective 1) and mysd (objective 2), and explore new reaction manifolds and processes enabled by the new chemistry of atp grasp enzymes (objective 3). as such, this work will likely add to our fundamental understanding of the consequences of protein sequence variation upon protein structure and function. furthermore, the outlined studies will likely provide fresh information about the functional scope of the atp grasp enzyme superfamily in nature,

uncover hidden chemical **\*\*diversity\*\*** and biological processes, and open up longer term applications of these imine-forming enzymes in biotechnology. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Enhancing Laser Based Ion Sources with High Data Rate Techniques

Awardee: Ohio State University

Amount: \$477,683.00

Abstract: as laser technology continues to improve, it is important to investigate how laser interactions with matter can be better controlled and optimized to develop new applications. this research project will investigate two methods to enhance intense laser interactions in order to accelerate protons and ions. one method involves using a machine learning algorithm, which is a form of artificial intelligence, to control the laser system. the other method involves splitting the laser pulse into two beams and using the constructive interference to as much as double the intensity on target without requiring additional laser energy. the goal of both methods is to maximize the numbers and the energies of the protons and ions ejected from intense laser interactions. the intellectual products of this research may have a profound impact on efforts to use intense laser systems to perform proton radiography for a variety of biomedical, industrial, and defense purposes. the project will support several graduate and undergraduate students, and its members will be actively involved in several efforts to increase cultural, socioeconomic, and gender **\*\*diversity\*\*** in stem. there is great potential for intense laser systems to become a useful source of energetic ions for a variety of scientific and engineering applications, but the properties of laser accelerated protons and ions are typically far from ideal and the peak ion energy scales weakly with laser intensity. this project will address these problems by investigating two complementary techniques to enhance and control laser interactions with solid density targets. specifically, machine learning

methods will be used to control multiple experimental parameters on intense laser systems to examine how much optimization and control over the resulting proton spectrum can be achieved. the other technique involves using the constructive interference of two laser pulses to significantly increase the effective intensity and absorption of laser light. both techniques leverage high repetition rate laser systems such as the khz repetition rate extreme light intense laser system at wright patterson air force base, which will be involved in this project. particle-in-cell simulations will be performed to better understand optimal conditions for ion acceleration and to understand the physics of why the double pulse technique is so effective. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: BRITE Pivot: Machine Learning Enabled Rapid and Robust Three-Dimensional Nanomanufacturing

Awardee: Purdue University

Amount: \$475,587.00

Abstract: three-dimensional (3d) printing is one of the most important manufacturing technology developments in recent years for applications ranging from prototyping and product visualization to building functional materials and devices. nanoscale 3d printing has been used to produce a wide range of complex 3d nanostructures and nanodevices with unprecedented properties and

functionalities. however, the slow speed, variable quality and poor reproducibility of current 3d nanoprinting methods, such as point-by-point laser printing, are barriers for their adoption to commercial-scale manufacturing. machine learning (ml) and artificial intelligence (ai) are ideally suited for improving and assuring the quality of the printed structures. this boosting research ideas for transformative and equitable advances in engineering (brite) pivot award develops ai-guided, ml-enabled 3d nanoprinting methods to improve the speed, scale, print quality and robustness of the printed structures and devices. these ai and ml tools for 3d nanomanufacturing enable new applications, such as sensors and wearables, that benefit several sectors of the economy and contribute to us competitiveness and global leadership in advanced nanomanufacturing. this project contributes to **\*\*diversity\*\***, equity and inclusion by recruiting students from underrepresented groups and engaging them in research and education in ai, ml and 3d nanoprinting technologies, thus developing a diverse workforce in advanced manufacturing. the pi has extensive experience and expertise in laser-based nanomanufacturing and device manufacture. recent efforts by the principal investigator (pi)'s group have resulted in the development of a rapid, continuous, layer-by-layer 3d nanoprinting technology. this project allows the pi to acquire new expertise in ml and ai methods through in-depth investigations and applications of these methods to develop rapid and robust 3d nanoprinting technologies. this includes studies and evaluations of various ml and ai methods and selection and implementation of appropriate methods for rapid 3d nanoprinting. the research involves developing methods that combine physics-based models with advanced ml algorithms such as adaptive learning and transfer learning. the femtosecond laser-based 3d nanoprinting process involves understanding the fundamentals of controlling the laser beam characteristics, such as beam size and scan rate, its propagation in the optical system and the laser-induced reactions in the photopolymers. the physics-based models and laser photo-polymerization experiments provide key data and guidance for the development of ml and ai analytic tools for process control and optimization. furthermore, the project studies approaches to develop ml and ai tools using a relatively small amount of experimental data. using results of various printed structures, ml and ai

algorithms are developed to guide the process of printing arbitrary, user-defined structures with high precision. this project advances knowledge in ai-guided, ml-enabled femtosecond laser-based photo-polymerization as a platform for rapid and robust 3d nanomanufacturing. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: A comparative study of the impact of displacement on multilingualism and language endangerment

Awardee: SUNY at Buffalo

Amount: \$474,457.00

Abstract: communities all over the world are frequently impacted by displacement due to events such as natural disasters or political conflict, and displaced people often experience significant changes to their linguistic environment when the areas that they move to are dominated by different languages than those spoken in the regions that they come from. for instance, members of a rural

community speaking an endangered language who move to an urban area after a natural disaster may shift from an environment where most people they meet during the course of a day speak their first language to one where only their close friends and family members do. similarly, refugees fleeing their homes may find themselves in camps occupied by people from many different areas who do not, at least initially, share a common language. moreover, displacement may change more than just the primary language that an individual uses in their day-to-day lives. in many parts of the world, users of languages associated with small communities are multilingual and actively use three or more languages. when they move, they may learn a new language but also stop using other languages that they know, including endangered languages. the impact of displacement on multilingualism and endangerment has yet to be systematically investigated, even though increased knowledge in this domain would help refine policies intended to support minority language maintenance and to improve the conditions of displaced people. this project studies three communities with demonstrated linguistic \*\*diversity\*\* that have experienced recent displacement in different ways. one community is currently experiencing displacement due to active political conflict, and another experienced displacement due to conflict that was resolved decades ago. the third community is a refugee camp housing displaced individuals from a linguistically diverse neighboring region. by studying language use across these three communities, the investigators are able to conduct a comparative analysis of how displacement impacts language vitality in multilingual contexts. the investigators use a range of qualitative and quantitative methods to collect data, including ethnographic observation, sociolinguistic interviews, and language proficiency assessment tasks. documentary records of language use among displaced people will also be created. the project is innovative in that it emphasizes understanding the social dynamics that promote language vitality rather than focusing on endangerment primarily as an outcome of global trends. this project also strengthens connections between linguistics, political science, and other disciplines studying peace and conflict. the project's outcomes can inform the study of societal resilience in the face of adversity. its results also have the potential to inform government policies seeking to promote the

use of minority languages by giving policy makers a clearer perspective of the factors that contribute to speakers continuing to use those languages. results also have the potential to lead to actionable recommendations for organizations that work with displaced people. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: IntBIO COLLABORATIVE RESEARCH: Deep Time, Development, and Design: Evolution of shark skin teeth from genotype to phenotype to prototype.

Awardee: Yale University

Amount: \$474,066.00

Abstract: the skin of sharks is unique among vertebrate animals because it contains tooth-like scales, called dermal denticles, that create a hard external armor. these tooth-like denticles evolved over millions of years and equip the shark with hydrodynamic skin that reduces the cost of moving through the water. this advanced streamlining is currently a subject of great interest, with many industries attempting to take advantage of shark skin technology to create more efficient swimming designs. this project aims to provide a complete integrated understanding of shark denticles: how they form in embryonic sharks, how denticle shape has changed over years of evolution, and which denticle types are the best for drag-reduction and further design advances. this knowledge will enable better use of shark skin technology to make advanced design solutions that help to make a better and more environmentally friendly world. for example, one possible use of shark skin technology is the development of surface structures on airplanes or boats to reduce drag during movement and decrease fuel emissions. in addition to its scientific impact, this project has impact on the stem workforce by supporting principal investigators and trainees across a wide range of career stages and by providing a unique, much-needed accessible research training program for undergraduates with disabilities in interdisciplinary research. the shape and pattern of shark skin

teeth, or denticles, has been refined over millions of years of evolution for functional improvements in aquatic locomotion. this project addresses the evolutionary and developmental trajectories that have led to a vast **\*\*diversity\*\*** of shark skin denticle types with the goals of determining why sharks have different shaped denticles among and within species and what functional advantages these different denticle shapes might offer these animals. from an integrated developmental, genetic, and evolutionary framework, the project will investigate how denticles develop and what factors lead to changes in shape. the approach will include studies of embryonic denticle development from the level of single cell transcriptomics to phenotypes and function to learn what key genes are essential to the production of various denticle shapes in a range of shark species and how these shapes are achieved via developmental innovation. goals include understanding what shapes are most efficient for drag-reduction in both modern and extinct species to enable modeling and testing of new engineering designs to reduce drag in air- and water-borne vehicles and devices. combining 3d printing with engineering methods, new shark-inspired surface structures will be used to create a shift in design solutions for a changing and more environmentally friendly world. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Strategic Course-based Adaptations of an Ecological Belonging Intervention to Broaden Participation in Engineering at Scale

Awardee: Purdue University

Amount: \$471,103.00

Abstract: this project aims to serve the national interest by increasing the number and **\*\*diversity\*\*** of engineers produced in the united states. while science overall has made great progress in increasing the participation of women, engineering has made no overall progress in the last 20 years, with women continuing to earn only 20% of engineering bachelor?s degrees each year. improving retention in the first two years of engineering programs is important in addressing ongoing attrition. in particular, engineering will become more inclusive when the concerns that many students have about feeling alone in thinking they are incapable of mastering the course?s content are addressed. here, short interventions will be implemented that reveal to students that most of the students in their class have these same concerns, that previous students just like them with similar concerns have successfully completed this coursework, and that their instructor believes they are capable of succeeding. prior research by the project team using the intervention in first-year courses has shown that these interventions can entirely eliminate course retention differences by gender as well as by race/ethnicity. a new method for customizing this intervention will be developed, tested, and further improved so that it can have similar strong benefits in many different courses and many different universities. simple interventions that can be easily and scientifically customized to many contexts may have potential for significantly improving engineering outcomes across the united states. this project uses an ecological-belonging intervention approach that only requires a one-class or one-recitation session to implement and has been shown to erase long-standing achievement gaps by gender and race/ethnicity in several introductory stem courses. however, while

simple, the intervention cannot involve a fixed script for different university and course contexts. rather, the content of the intervention needs to be customized to the local context in order to address the specific concerns students have in that specific context. this project brings a highly interdisciplinary team across three strategically-selected universities with the goal of developing an approach to identify which 1st and 2nd year courses need this intervention, reveal student concerns in that course, adapt the intervention to address those concerns, and address other pragmatic constraints of how that course is taught. this systematic approach also includes processes for onboarding all the instructors of the given course. in answering a set of seven core research questions, the project intends to expand knowledge about 1) where (on which outcome variables), when (in which contexts, for which students), and why the ecological belonging intervention has positive effects, and 2) the extent to which this intervention on its own has measurable impacts on the overall problem of representation in the larger challenge of representation within the large engineering pathways that have struggled with representation. this kind of foundational knowledge is critical to making decisions about when to apply the intervention as well as providing important insights into how to apply the intervention. the nsf iuse: ehr program supports research and development projects to improve the effectiveness of stem education for all students. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: WoU-MMA: Galactic Gamma-Ray Astrophysics with HAWC (UW-Madison Group Grant)

Awardee: University of Wisconsin-Madison

Amount: \$470,557.00

Abstract: the high-altitude water cherenkov observatory (hawc) is located at 4100 m above sea level near puebla, mexico. the detector has monitored the gamma-ray and cosmic-ray sky in the energy range from 100 gigaelectronvolts (gev) to 100 teraelectronvolts (tev) with a nearly 100% duty cycle

and a sensitivity unprecedented for a survey instrument, offering an exceptional view into the cosmos. this award provides funding for the uw?madison hawc group to research scientific areas in which hawc can make unique contributions: a search for tev halos surrounding middle-aged pulsars identified by radio and gev gamma-ray observations and a search for microquasars. the key questions motivating these studies include: are tev halos a universal feature of middle-aged pulsars? what drives the formation of tev halos? how do microquasars produce high-energy emissions? can they emit other high-energy messengers such as neutrinos? the hawc group is in the wisconsin icecube particle astrophysics center (wipac), a scientific center at uw-madison with researchers involved in a range of particle astrophysics projects, including the icecube observatory, the askaryan radio array, the hawc experiment, and the cherenkov telescope array. the pi will join the vibrant education and outreach activities of the center and contribute to educating and training future leaders in the field of particle astrophysics. she will lead an effort to support women and gender minorities at the center. along with other colleagues, she will initiate monthly or bi-monthly social events to gather up female and gender minority (such as people who are transgender or nonbinary) students, postdocs, and researchers at wipac. these **\*\*diversity\*\*** meetings will also be open and will facilitate interactions between the local undergraduates, graduate students, and researchers working in particle astrophysics. the study of tev halos and microquasars is closely related to the understanding of high-energy neutrinos. a population of tev?pev neutrinos with astrophysical origin has been observed by the icecube observatory since 2013. the origin of the bulk of the icecube neutrinos remains a mystery. recent multi-messenger follow-up observations provide hints toward the first neutrino sources, including the blazar txs 0506+056 and the vhe gamma-ray emitting region surrounding the pulsar psr j1907.9+0602, mgro j1908+06. with an overlapping energy window, hawc?s observation of these two types of sources will provide important information for neutrino studies. the gamma-ray analyses will be combined with the study of high-energy neutrinos. microquasars are also candidate neutrino sources. the pi will work with the icecube group on the multi-messenger study of the vhe gamma-ray sources, and in particular, to explore the

possibility of a joint analysis of hawc and icecube observations of the potential sources. as a first attempt, they will use the hawc spectra to derive the number of expected neutrinos from each source, assuming that protons produce the gamma-ray emission. the results will be compared with the icecube observation of these sources to understand the role of microquasars as high-energy neutrino emitters. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Frameworks: Convergence of Bayesian inverse methods and scientific machine learning in Earth system models through universal differentiable programming

Awardee: Dartmouth College

Amount: \$461,611.00

Abstract: understanding and quantifying parameter sensitivity of simulated systems, such as the numerical models of physical systems and mathematical renderings of neural networks, are essential in simulation-based science (sbs) and scientific machine learning (sciml). they are the key ingredients in bayesian inference and neural network training. seizing on the opportunity of emerging open-source earth system model development in the julia high-level programming language, this project is endowing these open-source models with automatic differentiation (ad) enabled derivative information, making these converging data science and simulation-based science tools available to a much broader research and data science community. enabling a general-purpose ad framework which can handle both large-scale earth system models as well as sciml algorithms, such as physics-informed neural networks or neural differential equations, will enable seamless integration of these approaches for hybrid bayesian inversion and bayesian machine learning. it merges big data science, in which available data enable model discovery with sparse data science, and the model structure is exploited in the selection of surrogate models

representing data-informed subspaces and fulfilling conservation laws. the emerging julia language engages a new generation of researchers and software engineers, channeling much needed talent into computational science approaches to climate modeling. through dedicated community outreach programs (e.g., hackathons, minisymposia, tutorials) the project team will be working toward increasing equity, **\*\*diversity\*\***, and inclusion across the participating disciplines. the project is developing a framework for universal differentiable programming and open-source, general-purpose ad that unifies these algorithmic frameworks within julia programming language. the general-purpose ad framework in julia leverages the composability of julia software packages and the differentiable programming approach that underlies many of the sciml and high-performance scientific computing packages. compared to most current modeling systems targeted for hpc, julia is ideally suited for heterogeneous parallel computing hardware (e.g., cuda, rocm, oneapi, arm, powerpc, x86 64, tpus). the project is bringing together expertise in ad targeted at earth system data assimilation in high performance computing environments with sciml expertise. the project team is working with the julia computing organization and package developers to ensure sustainability of the developed frameworks. the project's earth system flagship applications consist of (i) an open-source, ad-enabled ocean general circulation model that is being developed separately as part of the climate modelling alliance (clima), and (2) an open-source, ad-enabled ice flow model. each of these application frameworks is being made available to the community for science application, in which derivative (gradient or hessian) information represent key algorithmic enabling tools. these include sciml-based training of surrogate models (data-driven and/or model-informed), parameter and state estimation, data assimilation for model initialization, uncertainty quantification (hessian-based and gradient-informed mcmc) and quantitative observing system design. academic and industry partners are involved, who are using the frameworks for developing efficient power grids, personalized precision pharmacometrics, and improved eeg design. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Ecological legacy effects of megacarcasses in African savanna ecosystems

Awardee: Marquette University

Amount: \$460,049.00

Abstract: large animals such as elephants and rhinoceros, called "megafauna" for their extreme

size, have outsized impacts on the ecosystems they live in. they engineer their environments by knocking down trees and grazing grasses to create large lawns, helping to form habitats that facilitate other animals. but, there is little research that addresses the impact that the carcasses of these megafauna, or "megacarcasses", have on ecosystems after they die. their carcasses represent huge sources of nutrients that have a long-lasting ecological legacy on the areas of ecosystems where their carcasses occur. for example, african elephants are the largest land animals, but almost nothing is known about how the nutrients from their massive carcasses (up to 6,000 kg) affect savanna ecosystems. this award asks the main question: how do elephant megacarcasses affect the ecology of african savannas? the work will address how these megacarcasses affect nutrient cycling in the soil by microbes, plant primary production and species **diversity**, and herbivory by vertebrate herbivores, such as zebra and giraffe, and invertebrate herbivores, such as grasshoppers. this research will support the mentoring of 1 postdoctoral scholar, graduate and undergraduate students in ecology as well as science communication and outreach. the main broader impact will be the production of a scientific documentary, the legacy of megaherbivores, which will follow the life and death of an elephant in the african savanna, that will put the life cycle of these elephants into broader ecological context, understanding how they impact ecosystems and the current implications for ecosystems facing their disappearance. to address the overarching question, the award will use elephant carcasses of different ages (up to 15+ years old) in kruger national park (knp), south africa. combining soil (physical, chemical and biological properties), plant (productivity and **diversity**), and herbivore (vertebrate and invertebrate) surveys at 50 megacarcass sites along with greenhouse experiments, the award will assess how nutrient pulses from elephant carcasses drive integrated responses of ecosystem processes. importantly, the elephant megacarcasses are distributed across gradients of rainfall (375-700 mm) and soil fertility (less-fertile sandy, granitic soils vs. more-fertile clayey, basaltic soils) in knp. these gradients of rainfall and soil nutrients provide a robust experimental framework for testing how the abiotic environment impacts the ecosystem-level legacy effects of terrestrial

megacarcasses. finally, by combining the data from the field on the effects of megacarcasses on ecosystem processes with a database of elephant population across knp, the researchers will use ecological modeling to show how the distribution of megacarcasses generates variability in ecosystem processes across the savanna landscape as elephants naturally die over time. this study will represent the first examination of the ecological legacies of megacarcasses on terrestrial ecosystems. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Precision Tests of Fundamental Physics via Light Pseudoscalar Mesons

Awardee: University of North Carolina at Wilmington

Amount: \$459,754.00

Abstract: understanding how quarks and gluons confine themselves into the neutrons and protons that make the elements, and searching for new physics beyond the standard model (sm) of particle physics are two frontiers in physics. the primary goal of this project is to perform two cutting-edge experiments, primex-eta and jlab eta factory (jef), at jefferson lab to explore both fundamental topics with sensitivities not previously achievable. these measurements will shed light on some fundamental questions: what is the origin and dynamics of quantum chromo dynamic confinement? what is the nature of dark matter that constitutes 85% of matter and what is the cause for the asymmetry of matter and antimatter observed in the universe? the scope of this project, including hardware development, performance of the actual experiment and data analysis, will provide advanced training for a postdoctoral researcher and a group of undergraduate students. students will acquire significant skills in hands-on experimental techniques, data analysis and computation, as well as critical thinking and problem-solving abilities to fulfill the undergraduate curricula and prepare them for careers in stem fields. the opportunities for young researchers (postdoc and students) working at jefferson lab will enhance their experience and global perspectives. the female pi of this

project serves as a role model and promotes **diversity** and inclusion in the stem fields. the primex-eta experiment will measure the  $\eta$  radiative decay width at  $\sim 3\%$  precision via the primakoff effect, using the existing gluex apparatus with a new calorimeter consisting of  $12 \times 12$  array of pbwo4 crystals. it will resolve a longstanding discrepancy ( $\sim 3\%$ ) between the previous experimental results using the primakoff effect and  $e^+e^-$  collisions, and will offer accurate determinations of the light quark-mass ratio and the  $\eta$ - $\eta'$  mixing angle. the jef experiment will measure various  $\eta$  and  $\eta'$  decays with emphasis on rare modes, producing a clean dataset with background suppression of a factor of two orders of magnitude compared to all previous experiments. in addition to the baseline gluex apparatus, the jef experiment will require an upgraded forward calorimeter (fcal-ii) with a high-granularity, high-resolution pbwo4 crystal core in the central region that minimizes shower overlaps and optimizes the resolutions of energy and position. the data collected from the jef experiment will provide sensitive probes to: (a) explore the role of scalar meson dynamics in chiral perturbation theory for the first time; (b) tighten the uncertainty in the light quark mass ratio by the  $\eta \rightarrow \pi\pi$  dalitz distributions; (c) search for various sub-gev dark gauge boson candidates (including vectors, scalars and axion-like particles) by improving the existing bounds by more than two orders of magnitude and is complementary to the ongoing worldwide efforts at high-energy collider and underground facilities; and (d) provide the best direct constraints for c-violating, p-conserving new forces. as an experiment spokesperson, the pi will play a leadership role in both primex-eta and jef. the pi and her team will: (1) analyze the data collected in the phase i run of primex-eta, prepare and perform the phase ii run in fall 2021; (2) develop an upgraded fcal-ii and prepare the jef experiment for the anticipated run in 2024; (3) continue the service responsibility for maintaining and operating the low-granularity pair spectrometer detectors to control the photon flux in hall d. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Leveraging the Power of Reflection and Visual Representation in Middle-Schoolers' Learning During and After an Informal Science Experience

Awardee: Northwestern University

Amount: \$458,419.00

Abstract: this project addresses a longstanding problem in informal science education: how to increase the likelihood of consequential science, technology, engineering, and mathematics (stem) learning from short duration experiences such as field trips. although informal learning experiences can greatly contribute to interest in and knowledge of science, there is a shared concern among educators and researchers that students may have difficulty recalling and using scientific information

and practices emphasized during these experiences, even though doing so would further their science learning. nonetheless, science learning is rarely, if ever, a "one-shot deal." children acquire knowledge about science cumulatively across different contexts and activities. therefore, it is important that informal science learning institutions identify effective practices that support the consolidation of learning and memory from exhibit experiences to foster portable, usable knowledge across contexts, such as from informal science learning institutions, to classrooms, and homes. to this end, this research in service to practice project seeks to harness the power and potential of visual representations (e.g., graphs, drawings, charts, maps, etc.) for enhancing learning and encouraging effective reflection during and after science learning experiences. the project promises to increase learning for the 9,000+ 5th and 6th grade students from across the rurality and growing **\*\*diversity\*\*** of the state of maine who annually participate in labventure, a 2.5-hour exploration of the gulf of maine ecosystem at gulf of maine research institute. the research will provide new and actionable informal science learning practices that promote engagement with visual representations and reflection, and science understandings that can be applied broadly by informal science institutions. this project is funded by the advancing informal stem learning (aisl) and the discovery research prek-12 (drk-12) programs. it supports the aisl program goals to advance new approaches to, and evidence-based understanding of, the design and development of stem learning in informal environments. it supports the drk-12 program goal of enhancing the learning and teaching of stem by prek-12 students and teachers. the project is grounded in the idea that visual representations, including drawings, can both enhance science learning and encourage reflection on doing science that can support extension of that learning beyond a singular informal science experience. the project uses design-based research to address the following research questions: (1) does reflection during an informal science learning experience promote students? retention and subsequent use of science information and practices that are part of the experience? (2) does interpreting and constructing visual representations, such as drawings, improve students? understanding and retention of information, and if so, how and when? and (3) does combining visual representations

and narrative reflections confer benefits on students? science learning and engagement in science practices both during the informal learning experience, and later in their classrooms and at home? these questions will be pursued in collaboration with practitioners (both informal educators and classroom teachers) and a diverse team of graduate and undergraduate student researchers. approximately 600 student groups (roughly 3000 individual students) will be observed during the labventure experience, with further data collection involving a portion of these students at school and at home. the project will yield resources and video demonstrations of field-tested, empirically based practices that promote engagement with visual representations and reflection, and science understandings that can travel within students' learning ecosystem. in support of broadening participation, the undergraduate/graduate student researchers will gain wide understanding and experience connecting research to practice and communicating science to academic and nonacademic audiences. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Did small, non-fossilizing plankton dominate primary productivity and shape the recovery of calcareous plankton after the end Cretaceous mass extinction?

Awardee: University of Colorado at Boulder

Amount: \$458,264.00

Abstract: phytoplankton, which live in the surface ocean, produce organic matter from sunlight and carbon dioxide. this primary production forms the base of most marine food webs and is a critical part of the global carbon cycle. in the modern ocean plankton are being impacted by warming and ocean acidification. natural changes in ocean temperature and chemistry in the geologic past can help us understand the long-term effects of stressors such as warming and acidification. the cretaceous-paleogene (k-pg) mass extinction event ~66 million years ago was one such time of global change. calcareous (fossil-forming) nanoplankton were one of the dominant primary

producers in the cretaceous ocean. however, 93% of species of this group went extinct at the k-pg boundary, and they were never again as dominant. previous studies of the plankton response to the k-pg event have generally been limited to studies of species which leave a physical fossil record. thus, these studies provided only a partial view of ancient plankton ecosystems. the proposed work will overcome this limitation by using chemical fossils called biomarkers. these new data will be used together with traditional physical fossils to reconstruct changes in the marine plankton community following the k-pg event. it has often been assumed that non-fossilizing phytoplankton filled the gap left by the decline in calcareous nannoplankton. this study will help test that hypothesis. documenting the changes in both non-fossilizing and fossilizing plankton will improve our understanding of long-term changes in plankton ecology, and of how those changes could alter the ocean carbon cycle. this project will train early career researchers and undergraduate students, and will disseminate results to broader audiences through outreach and educational activities in partnership with organizations and programs in austin, tx and boulder, co. the project will develop datasets of lipid biomarkers, calcareous nannoplankton, and planktic foraminifera from 5 sites in tunisia, spain, and the us gulf coast. three sites in tunisia (el kef, elles, and el melah) represent a depth transect on a continental shelf (paleodepths of 200-500 m), caravaca represents deeper water (~600-1000 m), while brazos represent a shallow shelf which will allow us to test regional variability between north africa and the us gulf coastal plain. these data will allow tests of the following hypotheses: 1. a low-**diversity** assemblage of non-fossilizing phytoplankton bloomed in the aftermath of the k-pg extinction, during the time of low **diversity** calcareous nannoplankton ?disaster? assemblages. 2. subsequent recovery of calcareous nannoplankton **diversity** is associated with a decline in non-fossilizing phytoplankton. 3. shifts in the heterotrophic planktic foraminifera assemblages are tied to turnover in the whole autotrophic plankton assemblage. 4. the post-extinction community of primary producers was dominated by smaller phytoplankton like algae and cyanobacteria, and would have increased carbon recycling in shallow waters and reduced carbon export to the deep sea. the study will improve our understanding of the recovery after the

end cretaceous mass extinction and in our overall understanding of the role of plankton ecology in marine ecosystem change. additionally, reconstructing the whole plankton ecosystem, and not just the part that fossilizes, would represent a significant improvement of our toolkit to investigate ancient oceans. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: The Simpson Neutron Monitor Network

Awardee: University of Wisconsin-River Falls

Amount: \$453,164.00

Abstract: this three-year collaborative project is focused on building of a network of ground-based cosmic-ray monitors, called neutron monitors (nms), operated by a consortium of three u.s. academic institutions, namely universities of new hampshire, delaware and wisconsin-river falls. invented by prof. john simpson in 1948, following his experience on the manhattan project, nms have been used to detect and measure radiation in space, starting almost ten years before the space age. they are stationed on the ground all over the globe, providing continuous measurements of cosmic radiation for over a half century. nms measure the trends and changes in the radiation levels in space, which is critical information for travel by astronauts to the moon and mars. they can also detect intense, short-term bursts of radiation from the sun that reach the ground. all this activity is driven entirely by what the sun is doing. nms are robust and reliable and have assumed a new importance in recent years when used in conjunction with the international fleet of spacecraft and with neutron monitors in other countries. now, all the nms sponsored by the u.s. are being linked into what will be the simpson neutron monitor network, which will make it more efficient to coordinate operations and science. during this three-year collaborative project, the consortium will carry out this research, teasing new information out of these heritage instruments and providing researchers around the world with up-to-date radiation climate data. cosmic rays entering the earth's

atmosphere are messengers informing us about large-scale heliosphere structure, local space environment and solar activity. they have already passed through and interacted with the interplanetary magnetic field, and they carry information of its detailed structure. some of these cosmic rays possess enough energy to reach the ground. a nm is a ground-based particle detector that records the nucleonic component in particle showers. this directly correlates with the number of high energy cosmic rays striking the earth's atmosphere. the analysis of these data is used to build an understanding of the sun's influence on the solar system. because of the large detector volume exploited by ground-based stations, neutron monitors remain the state-of-the-art instrumentation for measuring rigidity  $>1\text{gv}$  cosmic rays. the programmatic linking of these instruments run by the universities of new hampshire, delaware and wisconsin-river falls will secure a continuity of quality data for the global community, as called out in the national space weather plan and congressional legislation. the data from these instruments are used by many, including, space weather predictors, industry, space scientists, homeland security and hydrologists. the nm stations span a wide range of latitudes, from the south pole to the arctic regions. the contributors to the nm signal include cosmic rays from the galaxy that are heavily modulated by solar activity and from the sun itself in the form of high energy bursts of protons. the variability of these agents reveals conditions in interplanetary space, general solar activity and the fundamental processes that produce cosmic rays throughout the universe. with today's computing resources, we better understand how these instruments detect radiation, and the consortium will thus be able to extract new information from these workhorse devices. this will shed new light on how the distribution of cosmic rays varies with time, geography and particle energy. the consortium will study how to permanently secure the operations of the monitor network and intelligent ways of expanding the network to complement those at existing sites. the education and outreach goals of the project include a research position for a postdoc, a wide variety of opportunities and experiences for undergraduates, as well as opportunities for high school and elementary school students. the research and epo agenda of this collaborative project supports the strategic goals of the ags division in discovery, learning,

**\*\*diversity\*\***, and interdisciplinary research. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Collaborative Research: Exploring the interplay between form and function: the force-velocity trade-off in the spider predatory strike.

Awardee: Smithsonian Institution

Amount: \$453,107.00

Abstract: spiders are important predators of insects and other small animals, and the group has nearly 50,000 described species. they are one of the most diverse and numerous groups of animals and occupy a wide variety of habitats; spiders also play an essential role in controlling pest populations. while great advances have been made in understanding how spiders use silk and venom to capture prey, very little is known about the main feeding structures of spiders, the chelicerae. these in some respects function like jaws of vertebrates since they are used to grasp and process prey. this research focuses on how the chelicerae are used during the predatory strike, when the spider grasps the prey and injects it with venom, and how the shape, speed and strength of chelicerae vary in different groups of spiders. the researchers will compare the anatomy and movements of chelicerae in a wide variety of spiders to better understand the evolution of feeding in the group. this work will also examine details of the super-fast predatory strike, found in certain types of spiders, and determine how it evolved. in addition to revealing the function and evolution of spider chelicerae, the project introduces spider biology to the next generation of scientists, with outreach to several groups ranging from high-school students to postdoctoral scholars. results from this research will also be used to engage and educate the public, including school-aged children, through hands-on lessons that will be displayed at the national museum of natural history and used in a summer day camp at the university of maryland. this research focuses on the comparative

functional morphology of spider chelicerae, and tests the hypothesis that a fundamental biomechanical principle, the force-velocity trade-off, explains the diversification of their morphology and predatory strike dynamics. it is widely assumed that lever-based skeletomuscular systems are optimized to produce either high forces or high velocities, but not both simultaneously. predictions of the force-velocity hypothesis will be tested using a broad sample of species from across the spider tree of life, including the "trap-jaw" spiders, some of which have predatory strikes that are the fastest movements known among arachnids. structural details of the exoskeleton and musculature will be quantified through analysis of computed tomography scans and histological sections, and functional performance variables such as strike velocity will be measured through analysis of high-speed videos. a molecular phylogeny will be generated and used to provide the historical framework for examining the evolution of morphology and strike performance. phylogenetically-informed statistical analyses will be used to determine whether the correlations between form and function anticipated by the force-velocity trade-off are consistent with the biomechanical "diversity" observed in spiders. the results will offer insights into the evolution of form and function in skeletomuscular systems and provide a rich source of new information on spider biology. this award is co-funded by two programs in the directorate for biological sciences, the systematics and bio"diversity" science program in the division of environmental biology, and the physiological mechanisms and biomechanics program in the division of integrative organismal systems. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: GP-IN: CUSP: Connecting Underserved Students to Polar STEM

Awardee: University of Maine

Amount: \$452,008.00

Abstract: recent changes in the polar regions such as atmospheric warming, permafrost thaw, sea

ice decline, and glacier retreat, are having global impacts. understanding these polar changes and predicting their future global impacts require a wide range of future science, technology, engineering, and mathematics (stem) professionals. unfortunately, less than 25% of high school students in the united states receive earth systems science training and polar studies represents a very small component of what is taught. additionally, the majority of earth systems societal challenges disproportionately impact low income and underrepresented populations, yet there is a significant deficiency in the number of underrepresented students receiving training within these fields. in fact, most earth systems science programs lack gender, ethnic, and economic **\*\*diversity\*\***. effective environmental solutions require communication between scientists, policy-makers, and the public, and must also support all communities, in particular, those most at risk. the project aims to help remedy gaps in polar stem education by developing new opportunities for underrepresented high school students to engage in real polar stem education in the classroom and via field experiences. additionally, the project aims to train teachers in high schools to integrate polar stem experiences in their classrooms to increase polar stem literacy within the united states. the researchers specifically propose to help fill the gaps in polar earth systems science education within the united states by developing a collaborative consortium of education programs including the university of maine, juneau icefield research program (jirp), and several department of education funded upward bound programs across the united states to offer 1) new project-based field opportunities in polar stem for high school students from low income or first generation college families, 2) teacher training in polar earth systems sciences 3) help to teachers developing high school lessons using authentic polar stem data, and 4) research focused on determining if our field and classroom education program improves teaching and high-school student learning about polar environments. this project will specifically support justice, equity, **\*\*diversity\*\***, and inclusion, of underrepresented students within the polar geosciences and help develop a more diverse and representative next generation of science leaders in more communities across the united states. this award reflects nsf's statutory mission and has been deemed worthy of support through

evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Noble-Metal Nanocrystals in Metastable Phases

Awardee: Georgia Tech Research Corporation

Amount: \$450,000.00

Abstract: with funding from the macromolecular, supramolecular & nanochemistry program of the chemistry division, dr. younan xia of the georgia institute of technology and dr. manos mavrikakis of the university of wisconsin-madison will conduct fundamental research toward controlling the spatial arrangement (i.e. the crystal phase or structure) of atoms in nanocrystals. such control could provide a versatile means of tailoring the electronic structure and catalytic properties of metal nanocrystals, opening the door to the development of advanced catalytic materials key to energy conversion and key for the production of important chemicals and pharmaceuticals. an important goal is to enable cost-effective and sustainable use of precious metals, some of the scarcest elements in the earth's crust. the multi-disciplinary and collaborative nature of this project offers a natural vehicle to enrich the education and training experiences of all participants. the results from this project will be adapted to enhance classroom teaching, including the development of demonstrations (animations and experiments) related to key concepts in chemistry and chemical engineering. the investigators will promote **\*\*diversity\*\*** in higher education by engaging women, member of underserved groups in this research project. specifically, dr. younan xia and dr. manos mavrikakis are developing colloidal methods for the synthesis of metal (e.g., ruthenium) nanocrystals in non-conventional, metastable crystal phases, together with well-controlled shapes or surface structures. these nanocrystals may open up avenues for observing new phenomena, enhancing existing processes, and enabling innovative applications. currently, there are only a very limited number of reports on the synthesis of metal nanocrystals in metastable phases owing to the lack of a mechanistic understanding. through an integration of experimental studies and computational modeling, the

investigators seek to elucidate the trends and mechanisms involved in the synthesis, striving to establish experimental conditions for the reliable production of a specific crystal phase. the ruthenium nanocrystals will be used as seeds to template the deposition of other noble metals for the facile synthesis of core-shell nanocrystals featuring new, metastable crystal structures. in the context of structure-property relationships, the investigators will evaluate the catalytic activities of the metastable nanocrystals toward the oxygen evolution and oxygen reduction reactions. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Linking Matrix Composition with Spatially Resolved Mechanical Properties in Polymicrobial Biofilms

Awardee: Northwestern University

Amount: \$450,000.00

Abstract: this award will support research to understand the mechanistic underpinnings of biofilm mechanical and physical properties. biofilms are soft multi-component biological materials. they are made of microbial communities attached to surfaces and encased in polymeric substances. it is thought that these polymeric substances provide mechanical stability. detrimental biofilms cause billions of dollars per year of damage via biofouling or corrosion of ship hulls, heat exchangers,

water treatment and distribution infrastructure, membranes, and in the food, oil, and beverage industries. In addition, they account for 65% of infections that originate in hospitals, affecting 17 million people and causing at least 550,000 deaths annually in the US. Conversely, beneficial biofilms can clean water and remediate groundwater and soil. Despite the crucial relevance of biofilms to diverse industrial, medical, and environmental applications, little is known about how local biofilm mechanical properties are mediated by encasement composition, community **diversity**, and biofilm physical structure. This award will support fundamental research to understand the relationship between microscale biofilm mechanical properties, encasement and community composition, and physical structure. This work will study biofilms of increasing complexity, including complex environmentally-relevant mixed-culture biofilms. The results generated from executing this award will directly inform new strategies to manage biofilms in critical applications (e.g., remove when they are undesirable, and retain when they are beneficial), leading to significant cost savings. The project provides additional benefits, including diversifying the nation's STEM workforce through multidisciplinary training for underrepresented students at grade school, undergraduate, and graduate levels. This grant will advance our understanding of critical yet poorly understood interrelationships between molecular composition, physical structure, and mechanical properties in polymicrobial biofilms exposed to disparate environmental cues. The majority of the work to date on biofilm mechanical properties has employed macrorheological tools that neglect the inherent local heterogeneity in biofilms and has focused primarily on pure culture biofilms (e.g., *P. aeruginosa* alone) that are not representative of, and likely differ significantly in extracellular polymeric substances (EPS) composition and mechanical properties from, polymicrobial biofilms that are found in medical, environmental and industrial settings. Specifically, the research team will, 1) study local structure- composition-viscoelastic property relationships in biofilms; 2) study biofilm-substratum adhesion and cohesion properties; and 3) develop homogenization-based constitutive models to predict the multi-scale mechanical properties of biofilms. Project results will elucidate, for the first time, how microscale variations in EPS constituents (e.g., polysaccharides, proteins, eDNA) mediate

local heterogeneity in shear moduli and viscosity, adhesion strength, and cohesive fracture energy in dual and mixed-culture biofilms, and how environmental cues and microbial populations present modify this relationship. this improved understanding of spatially resolved structure/ composition-mechanical property relationships will provide the basis for rational management and control of biofilms. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Synthetic Control over MOF Particle Growth and Surface Chemistry

Awardee: University of Oregon Eugene

Amount: \$450,000.00

Abstract: non-technical summary     membranes based on metal-organic frameworks (mofs), which are three-dimensional (3-d) organic/inorganic compounds, attract intense interest for industrial petroleum refining and gas separations due to their exceptional tunability and synthetic **\*\*diversity\*\***. for mofs to reach widespread attraction and implementation in the industrial sector, however, researchers will be required to go beyond 3-d mofs and develop new types of mof nanoparticles, as they exhibit superior separation performance and generate membranes with superior stability. for the past two decades, bulk powders of mofs occupied the focus of academic mof research, but very recent attention has turned to preparing mof nanoparticles and polymer composites with precise control of particle sizes. despite preliminary demonstrations of the great potential of mof nanoparticles, key fundamental questions remain for achieving reproducible control over mof particle composition and for understanding how particle size and composition impact membrane performance. with this project, supported by the solid state and materials chemistry program in the division of materials research at nsf, prof. carl brozek at the university of oregon and his research group will investigate the chemical principles that control the precise sizes and compositions of mof nanocrystals. mechanistic growth models will be developed in the context of growth models established for other classes of materials so that these results inform the broad field of materials chemistry. similarly, the synthetic techniques pursued in this proposal will influence materials design beyond mof particles, by outlining fundamental tools for molecular control over materials across multiple size regimes. the proposed research is practically relevant to society because precise control over mof nanocrystal sizes will open new frontiers in improved gas separation membranes for industry and the opportunity for elevating mof application performance to becoming practically relevant.

technical summary     this project, supported by the solid state and materials chemistry program in the division of materials research at nsf, will investigate the fundamental growth mechanisms of metal-organic framework (mof) particles, develop methods to control particle surface

chemistry for enhancing their colloidal stability and interfacing with polymer composites, and understand the impact of size and surface composition on molecular- and charge-transport properties. tackling this goal will require basic investigation into the parameters that dictate particle sizes, defect incorporation, and surface functionalization. insight into controlling prenucleation crystal growth of materials in general, reproducible synthesis of mof-based heterostructure composites, and improving the practical relevance of mof materials will result from this research. broader impacts of this proposal include 1) integrating these research aims into educational outreach initiatives that communicate the science of carbon capture technology to underserved students, 2) fostering interdisciplinary training programs that pairs chemistry with architecture students to design air-purification modules, 3) sponsoring industry-academia seminar series on mof-based carbon-capture, and 4) implementing a teaching course on designing outreach initiative offered year-round to university of oregon (uo) chemistry phd students. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: CSBR: Rescuing and Sharing a Unique and Irreplaceable Fossil Collection at the Duke Lemur Center

Awardee: Duke University

Amount: \$442,704.00

Abstract: the duke lemur center is responsible for two unique and irreplaceable collections: the largest living population of lemurs outside of their native madagascar and a natural history collection that includes one of the most diverse primate fossil collections in the united states. the fossil collection ? with specimens from the united states, egypt, madagascar, and colombia ? helps researchers use the tree of life to connect lemur research to other primates, including humans. unfortunately, some of the most important fossils at the dlc, including some of the oldest lemur fossils and some of the oldest monkey fossils, are actively breaking down because unstable salt minerals were embedded in the specimens during fossilization. this project is a rescue mission to stabilize and preserve these fossils in physical and digital form. highly trained fossil technicians will remove salt minerals from the most endangered specimens and store the revitalized fossils in new specimen cabinets that better control the temperature and humidity around the specimens. the team will also create 3d scans of the specimens using x-rays. the scans create a back-up record of the

fossils in case they continue to deteriorate. the scans will be uploaded to morphosource, an online repository that allows educators, students, and researchers to examine fossils in 3d from any device with internet access. with a better-stabilized collection, the dlc fossil collection can open to the public for in-person and virtual tours, and online exhibits and curriculum guides will be created by the dlc education team using scans and 3d prints. the most unstable fossils in the collection come from locality 41 in the fayum depression in egypt. the site is one of the most fossil-dense terrestrial paleogene localities in africa. along with primates like catopithecus and plesiopithecus, the site preserves giant hyraxes, rodents, bats, snakes, birds, and carnivores. the tennis-court sized fossil deposit in the western desert of egypt was actively quarried in the 1980s through 2010s. the most fossil-rich sections were targeted by the excavation teams. this makes the collection at the dlc irreplaceable through additional fieldwork. this project partially supports a fossil preparator who will focus on the egyptian collection as well as other unstable materials in the collection. it also partially supports a digital tomographer who will use the duke microct scanner to generate scans of the most at-risk specimens, and the dlc data manager who will work with the tomographer to backup and upload scan data to morphosource. the data manager will lead the effort to add higher resolution specimen data to the dlc specify database, which will integrate with idigbio (idigbio.org) and the global bio\*\*diversity\*\* information facility (gbif.org). the project also supports microct scanner access and new specimen storage cabinets. the dlc education team will use these newly stable specimens to create curriculum-targeted tours and guides for north carolina k-12 students and visitors to the dlc. ultimately, exceedingly fragile fossil specimens will be available in-person and online to researchers, students, and the general public. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.

Title: Understanding and controlling low angle grain boundaries in additively manufactured metals

Awardee: University of California-Los Angeles

Amount: \$441,850.00

Abstract: non-technical abstract      additive manufacturing (am), or 3d printing, with its ability to integrate materials synthesis and manufacturing into a single print, is attractive for a broad range of technological applications and may help usher industry 4.0 revolution. however, a fundamental understanding of the processing-structure-property relationship in most am materials remains lacking. nearly all am materials are made of numerous crystals called grains. grains form interfaces when attached to each other. these interfaces can often control materials properties. it has been particularly challenging to understand and control grain interfaces in am materials, which may help us to achieve stronger and more bendable materials. this project advances understanding of the relationship between processing, interfaces between these grains, and resultant mechanical properties in a model 3d-printed material through an integrated experimental and computational effort. the ability to control these interfaces via 3d printing could allow the creation for high-performance structural materials for various engineering applications. the involvement of under-represented undergraduate research through samueli **\*\*diversity\*\*** program and collaborations with national laboratories provide educational and career advancement opportunities for young scientists in advanced manufacturing and materials science fields.      technical abstract

the objective of this project is to understand and control low angle grain boundaries (lagbs) in am metals and alloys. the research focuses on pure metals fabricated by laser powder-bed-fusion (l-pbf), which often contain a substantial fraction of lagbs that can lead to high strength, high ductility, and high thermal stability. the project aims at establishing mechanistic understanding of interconnections between laser processing parameters, interfacial microstructures (e.g., lagbs), and resultant mechanical properties. the research comprises of two major thrusts: thrust 1 involves controlled fabrication of model materials with various fractions of lagbs. an inverse pole figure orientation mapping using transmission electron microscopy (tem) is used to characterize interfacial structures and correlate their characteristics to the deformation kinetics parameters and in situ

synchrotron x-ray diffraction experiments. thrust 2 strives to develop processing sensitive models to correlate complex processing parameters and its thermal history with the observed microstructures. the processing model is tightly coupled with microstructure characterizations to reveal the fundamental relationship between the laser scan strategies and processing parameters and resultant microstructures. the mechanistic insights obtained by these studies could guide the optimization of laser processing conditions to create high performance structural materials for diverse applications. collaborations with national laboratories enhance the graduate student's research experience. partnership with the samueli \*\*diversity\*\* program to engage undergraduate students from under-represented groups into these research activities increases the \*\*diversity\*\* of the future stem workforce. this award reflects nsf's statutory mission and has been deemed worthy of support through evaluation using the foundation's intellectual merit and broader impacts review criteria.
